The Alliance commented that the NPRM MY 2016 analysis fleet had been updated with appropriate ratings of rolling resistance improvements, compared to the Draft TAR where vehicles were generally considered to have unimproved tires (meaning the Draft TAR assumed additional improvements were more achievable than in reality).¹⁴⁴³ The Alliance noted that the Draft TAR approach led to the CAFE model adding additional tire rolling resistance improvements even though manufacturers had already made significant improvements with that technology. This meant that the real-world fleet had little remaining opportunity for additional tire-related improvements, ultimately leading to the Draft TAR analysis underpredicting the amount of powertrain technology required for compliance.

The Alliance noted that it is possible to estimate rolling resistance features of a vehicle using road load coefficients, but the process requires various assumptions and is not very accurate. The Alliance concluded that the agencies' use of CBI to assign baseline technology levels correctly was an accurate and practical solution. Similarly, Ford commented in support of the agencies' low rolling resistance tire assignments in the baseline fleet, stating that the accuracy of the baseline fleet assessment had been considerably improved using actual tire rolling resistance data.¹⁴⁴⁴

HDS commented that the analysis fleet "accounts for the distribution of tires below 0.09 as 19% of vehicles in MY 2016 are modeled as having used ROLL10 and 25% of vehicles as having used ROLL20 in the base year, but there is no accounting for the ~25% of vehicles having RRC values 10 to 20% above the 0.09 RRC average."¹⁴⁴⁵ HDS concluded that "[a] stricter accounting of the baseline and, possibly setting specific lower limits for 2025 RRC by vehicle type (as done for aero drag in the PRIA) will show significant additional fleetwide effectiveness from RRC reduction which is a very cost-effective technology."

ICCT commented that the agencies made a "dramatic and unjustified" shift in baseline tire rolling resistance assignments from the 2015 fleet used in the Draft TAR to the 2016 fleet used in the NPRM.¹⁴⁴⁶ ICCT noted that per the agencies' updated baseline value, nearly 20 percent of all vehicles in the MY 2016 analysis fleet achieved 0.0081 (or better) rolling resistance value, and more than 26 percent achieve 0.0072 (or better). ICCT argued that rather than changing the definition of rolling resistance technology to include improvements beyond the baseline, the agencies instead redefined the technology available, reducing the number of vehicles that can use tire improvements in future compliance years within the modeling framework, which artificially forced companies to use other, more expensive technologies.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

ICCT stated that to substantiate the baseline rolling resistance assignments, the agencies need to show data on how these improvements are evident in the fleet and delivering benefits. ICCT alleged that if an improvement of that magnitude were true, it would be evident in fleet level miles-per-gallon and CO₂ levels; however, “none of the quantifiable mpg or CO₂ benefits that would be associated with these additional rolling resistance improvements were reflected with any real-world evidence in the model year 2016 fleet.” ICCT stated this seemed to be a case of the agencies “artificially burying efficiency technology in the baseline, rendering it unusable in the post model year 2016 compliance scenarios.”

ICCT also stated that the agencies must share absolute road load coefficients for each vehicle make and model in the baseline fleet, and the technical justification for each value, in addition to conducting two sensitivity analysis cases “assum[ing] that every baseline make and model is set to 0% rolling resistance improvement and set to the previous baseline rolling resistance (from the Draft TAR) to demonstrate how much the agencies’ decision to load up more baseline technology affects the compliance scenarios, as it appears that the agencies may have made a unsupportable and non-rigorous assumption about rolling resistance technology across the models.” ICCT concluded that because the changes were buried in the datafiles and unexplained, the agencies must issue a new regulatory analysis and allow an additional comment period for review of the methods and analysis.

Based on the comments from HDS and ICCT, the agencies reexamined available tire rolling resistance data. The assignment of ROLL20 technology was revised for some vehicle models based on information on the use of common tires across vehicles that shared a platform. As a consequence, for the final rule, only 20 percent of the MY2017 vehicle fleet is assigned ROLL20. The agencies will continue to investigate additional methods to improve the accuracy of this method, however as the Alliance and Ford noted, the accuracy of the baseline levels had been significantly improved over prior analyses by using actual tire RRC data. The agencies approach is consistent with the NAS recommendation to have two ROLL technology levels. The agencies determined that 30 percent rolling resistance improvement while maintaining other tire characteristics is unlikely to be available in the rulemaking timeframe.

The agencies considered a sensitivity case that assumed no mass reduction, rolling resistance, or aerodynamic improvements had been made to the MY 2017 fleet (i.e., setting all vehicle road levels to zero - MRO, AERO and ROLL0), in response to ICCT’s comment. While this is an unrealistic characterization of the initial fleet, the agencies conducted a sensitivity analysis to understand any affect it may have on technology penetration along other paths (e.g. engine and hybrid technology). Under the CAFE program, the sensitivity analysis shows a slight decrease in reliance on engine technologies (HCR engines, turbocharge engines, and engines utilizing cylinder deactivation) and hybridization (strong hybrids and plug-in hybrids) in the baseline (relative to the central analysis). The consequence of this shift to reliance on lower-level road load technologies is a reduction in compliance cost in the baseline of about \$300 per vehicle (in MY 2026). As a result, cost savings in the preferred alternative are reduced by about \$200 per vehicle. Under the CO₂ program, the general trend in technology shift is less dramatic (though the change in BEVs is larger) than the CAFE results. The cost change is also comparable, but slightly smaller (\$200 per vehicle in the baseline) than the CAFE program results. Cost savings under the preferred alternative are further reduced by about \$100. With the

lower technology costs in all cases, the consumer payback periods decreased as well. These results are consistent with the approach taken by manufacturers who have already deployed many of the low-level road load reduction opportunities to improve fuel economy.

Figure II-11~~Figure VI-21~~ shows the distribution of ROLL technology for the Draft TAR, NPRM and final rule. For the NPRM, 64 percent of the MY 2016 vehicle fleet was assigned ROLL0 and for the final rule, 59 percent of the MY2017 vehicle fleet is assigned ROLL0. This shows that the majority of the fleet is still at the ROLL0 technology level and there is still significant opportunity for the vehicle fleet to improve ROLL technology.

Figure II-11~~42~~ - Distribution of tire rolling resistance technology for the Draft TAR, NPRM and Final Rule

ROLL	Draft TAR (MY 2015 vehicle fleet)	NPRM (MY2016 vehicle fleet)	Final Rule (MY2017 vehicle fleet)
ROLL0	99.80%	64%	59%
ROLL10	0.1%	10%	21%
ROLL20	0.1%	26%	20%

c) *Rolling Resistance Adoption Features*

In some cases, low rolling resistance tires can affect traction, which may adversely impact acceleration, braking and handling characteristics for some high-performance vehicles. Similar to past rulemakings, the agencies recognized in the NPRM that to maintain performance, braking and handling functionality, some high-performance vehicles would not adopt low rolling resistance tire technology. For cars and SUVs with more than 405 horsepower (hp), the agencies restricted the application of ROLL20. For cars and SUVs with more than 500 hp, the agencies restricted the application of any additional rolling resistance technology (ROLL10 or ROLL20). The agencies developed these cutoffs based on a review of confidential business information and the distribution of rolling resistance values in the fleet.

Ford commented that the NPRM analysis appropriately limited the application of ROLL technology where it would be infeasible or would be at odds with the vehicles' intended function, characterizing that the decision to restrict application of ROLL10 and ROLL20 for high performance vehicles as reasonable.¹⁴⁴⁷

Accordingly, the agencies continued with the NPRM methodology of restricting certain ROLL technology for high performance vehicles. In the final rule, we restricted the ROLL technology to ROLL0 and ROLL10 for vehicles with greater than 405 hp and below 505hp. For vehicles greater than 505hp, we restricted the ROLL technology to ROLL0.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

d) *Rolling Resistance Effectiveness Modeling and Resulting Effectiveness Values*

As discussed above, the agencies updated the baseline rolling resistance value to 0.009, based on a thorough review of confidential business information submitted by industry, and a review of other literature. To achieve ROLL10 in the NPRM and for the final rule analysis, the tire rolling resistance must be at least 10 percent better than baseline (.0081 or better). To achieve ROLL20, the tire rolling resistance must be at least 20 percent better than baseline (.0072 or better).

HDS commented that the Autonomie modeling assumed no engine change when drag and rolling resistance reductions were implemented, as well as no change to the transmission gear ratios and axle ratios, which vary by transmission type but not by the tractive load.¹⁴⁴⁸ HDS stated that “reduction in rolling resistance is accompanied by axle ratio adjustments so that the engine operates at about the same load but at lower RPM. The EPA ALPHA model adjusts for this effect, which accounts for the difference in benefit estimates” between Autonomie and the ALPHA model simulations.

As stated in Section [Technology Effectiveness and Modeling], Autonomie builds performance-neutral vehicle models by resizing engines, electric machines, and hybrid electric vehicle battery packs only at specific incremental technology steps. To address product complexity and economies of scale, engine resizing is limited to specific incremental technology changes that would typically be associated with a major vehicle or engine redesign.¹⁴⁴⁹ Manufacturers have repeatedly told the agencies that the high costs for redesign and the increased manufacturing complexity that would result from resizing engines for small technology changes preclude them from doing so. It would be unreasonable and unaffordable to resize powertrains for every unique combination of technologies, and exceedingly so for every unique combination technologies across every vehicle model due to the extreme manufacturing complexity that would be required to do so. The agencies explained in the NPRM that the analysis should not include engine resizing with the application of every technology or for combinations of technologies that drive small performance changes to reflect better what is feasible for manufacturers.¹⁴⁵⁰

Compliance modeling in the CAFE model also accounts for the industry practice of platform, engine, and transmission sharing to manage component complexity and associated costs.¹⁴⁵¹ At a vehicle refresh cycle, a vehicle may inherit an already resized powertrain from

¹⁴⁴⁸ NHTSA-2018-0067-11985.

¹⁴⁴⁹ See 83 FR 43027 (Aug. 24, 2018).

¹⁴⁵⁰ For instance, a vehicle would not get a modestly bigger engine if the vehicle comes with floor mats, nor would the vehicle get a modestly smaller engine without floor mats. This example demonstrates small levels of mass reduction. If manufacturers resized engines for small changes, manufacturers would have dramatically more part complexity, losing economies of scale.

¹⁴⁵¹ Ford EcoBoost Engines are shared across ten different models in MY2019.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

another vehicle within the same engine-sharing platform that adopted the powertrain in an earlier model year. In the Autonomie modeling, when a new vehicle adopts fuel saving technologies (such as ROLL technology) that are inherited, the engine is not resized (the properties from the baseline reference vehicle are used directly and unchanged) and there may be a small change in vehicle performance.

Regarding customizing transmission gear ratios as rolling resistance changes are implemented, the agencies explained in [Section VI.A.2] that it is an observable practice in industry to use a common gear set across multiple platforms and applications. The most recent example is the GM 10L90, a 10-speed automatic transmission that used the same gear set in both pick-up truck and passenger car applications.¹⁴⁵² In Autonomie, optimization of transmission performance is achieved through shift control logic rather than customized hardware (e.g., gear ratios) for each vehicle line. The shift initializer routine was run for every unique Autonomie full vehicle model configuration to generate customized shifting maps. The algorithms' optimization was designed to balance minimization of energy consumption against vehicle performance.¹⁴⁵³ This balance was necessary to achieve the best fuel efficiency while maintaining customer acceptability by meeting performance neutrality requirements. See Section [Performance Neutrality] for more details. If the systems were over-optimized for our modeling, such as applying a unique gear set for each individual vehicle configuration, the analysis would likely over-predict the reasonably achievable fuel economy improvement for the technology. Over-prediction would be exaggerated when applied under real-world large-scale manufacturing constraints necessary to achieve the estimated costs for the transmission technologies.

As HDS noted, the EPA Draft TAR and Proposed Determination analyses performed using the ALPHA model adjusted the effectiveness of every technology combination assuming performance could be held constant for every combination, and did not recognize or account for the extreme complexity nor the associated costs for that impractical assumption. The NPRM and final rule analyses account for real-world practicalities and constraints related to both engine adoption and transmission adoption when other vehicle technologies are implemented, which explains some of the effectiveness and cost differences between the Draft TAR/Proposed Determination and the NPRM/final rule.

Figure II-12~~Figure VI-26~~ below shows the range of effectiveness used for the NPRM analysis for ROLL technologies.

Figure II-1344 – Final Rule Analysis ROLL Technology Effectiveness

e) Rolling Resistance Cost

For the NPRM, the analysis used DMC for ROLL technology from the Draft TAR and updated the values to reflect 2016\$ dollars. The agencies continued to use the same cost assumptions presented in the NPRM for the final rule, and updated the values to 2018\$ dollars. Table II-35Table VI-69 and Figure II-14Figure VI-23 show the different levels of tire rolling resistance technology cost.

Table II-35108 - Cost for tire rolling resistance technologies relative to ROLL0

Technology	Tire Rolling Resistance Technology Costs for MY 2017 (2018\$)		
	Direct Manufacturing Cost	Total Cost (includes RPE and Learning)	Incremental to
ROLL0	\$0.00	\$0.00	Base V
ROLL10	\$5.186	\$7.78	Base V
ROLL20	\$40.54	\$60.81	Base V

Figure II-1445 - Cost (RPE) for ROLL10 and ROLL20 Relative to ROLL0 in 2018\$

7. Other Vehicle Technologies

Four other vehicle technologies were included in the analysis—electric power steering (EPS), improved accessory devices (IACC), low drag brakes (LDB), and secondary axle disconnect (SAX) (which may only be applied to vehicles with all-wheel-drive or four-wheel-drive). The effectiveness of these technologies was applied directly by the CAFE model, with unique effectiveness values for each technology and for each technology class. This methodology was used in these four cases because the effectiveness of these technologies varies little with combinations of other technologies. Also, applying these technologies directly in the CAFE model significantly reduces the number of Autonomie simulations that are needed.

a) Electric Power Steering (EPS)

Electric power steering reduces fuel consumption and CO₂ emissions by reducing load on the engine. Specifically, it reduces or eliminates the parasitic losses associated with engine-driven power steering pumps, which pump hydraulic fluid continuously through the steering actuation system even when no steering input is present. By selectively powering the electric assist only when steering input is applied, the power consumption of the system is reduced in comparison to the traditional “always-on” hydraulic steering system. Power steering may be electrified on light duty vehicles with standard 12V electrical systems and is also an enabler for vehicle electrification because it provides power steering when the engine is off (or when no combustion engine is present).

Power steering systems can be electrified in two ways. Manufacturers may choose to eliminate the hydraulic portion of the steering system and provide electric-only power steering (EPS) driven by an independent electric motor, or they may choose to move the hydraulic pump

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

from a belt-driven configuration to a stand-alone electrically driven hydraulic pump. The latter system is commonly referred to as electro-hydraulic power steering (EHPS). As discussed in the NPRM, manufacturers have informed the agencies that full EPS systems are being developed for all types of light-duty vehicles, including large trucks.

EPS is also discussed in Section [Electrification Modeling in the CAFE model].

b) Improved Accessories (IACC)

Engine accessories typically include the alternator, coolant pump, cooling fan, and oil pump, and are traditionally mechanically-driven via belts, gears, or directly by other rotating engine components such as camshafts or the crankshaft. These can be replaced with improved accessories (IACC) which may include high efficiency alternators, electrically driven (i.e., on-demand) coolant pumps, electric cooling fans, variable geometry oil pumps, and a mild regeneration strategy.¹⁴⁵⁴ Replacing lower-efficiency and/or mechanically-driven components with these improved accessories results in a reduction in fuel consumption, as the improved accessories can conserve energy by being turned on/off “on demand” in some cases, driven at partial load as needed, or by operating more efficiently.

For example, electric coolant pumps and electric powertrain cooling fans provide better control of engine cooling. Flow from an electric coolant pump can be varied, and the cooling fan can be shut off during engine warm-up or cold ambient temperature conditions, reducing warm-up time, fuel enrichment requirements, and, ultimately reducing parasitic losses.

IACC is also discussed in Section [Electrification Modeling in the CAFE model].

c) Low Drag Brakes (LDB)

Low or zero drag brakes reduce or eliminate brake drag force by separating the brake pad from the rotor, either by mechanical or electric methods. Conventional disc brake systems are designed such that the brake pad is in contact with the brake rotor at all times. This is true even when the brakes are not being applied, and although the contact pressure is light in this case, this still produces some drag force on the vehicle.

LDBs have historically employed a caliper and rotor system that allows the piston in the caliper to retract,¹⁴⁵⁵ in turn pulling the brake pads away from the rotor. However, if pads are allowed to move too far away from the rotor, the first pedal application made by the vehicle operator can feel spongy and have excessive travel. This can lead to customer dissatisfaction regarding braking performance and pedal feel. For this reason, in conventional hydraulic-only

¹⁴⁵⁴ IACC in this analysis excludes other electrical accessories such as electric oil pumps and electrically driven air conditioner compressors.

¹⁴⁵⁵ The brake caliper pistons are used to push the brake pad against the brake rotor, or disc.

brake systems, manufacturers are limited by how much they can allow pads to move away from the rotor.

Recent developments in braking systems have resulted in brakes with the potential for zero drag. In these systems, the pedal feel is separated from hydraulics by a pedal simulator. This system is similar to the brake systems designed for hybrid and electric vehicles, where some of the primary braking is done through the recuperation of kinetic energy in the drive system. However, the pedal feel and the deceleration the operator experiences is tuned to provide a braking experience equivalent to that of a conventional hydraulic brake system. These “brake-by-wire” systems have highly tuned pedal simulators that feel like typical hydraulic brakes and seamlessly transition to a conventional system as required by different braking conditions. The application of a pedal simulator and brake-by-wire system is new to non-electrified vehicle applications. By using this type of system, vehicle manufacturers can allow brake pads to move farther away from the rotor and still maintain the initial pedal feel and deceleration associated with a conventional brake system.

In addition to reducing brake drag, the zero drag brake system provides ancillary benefits. It allows for a faster brake application and greater deceleration than is normally applied by the average vehicle operator. It also allows manufacturers to tune the braking for different customer preferences within the same vehicle. This means manufacturers can provide a “sport” mode, which provides greater deceleration with less pedal displacement and a “normal” mode, which might be more appropriate for day-to-day driving.

The zero drag brake system also eliminates the need for a brake booster. This saves cost and weight in the system. Elimination of the conventional vacuum brake booster could also improve the effectiveness of stop-start systems. Typical stop-start systems need to restart the engine if the brake pedal is cycled because the action drains the vacuum stored in the booster. Because the zero drag brake system provides braking assistance electrically, there is no need to supplement lost vacuum during an engine off event.

Finally, many engine technologies being considered to improve efficiency also reduce pumping losses through reduced throttling, and in turn there is less engine vacuum available to power-assist a conventional brake system. The reduction in throttling could require a supplemental vacuum pump to provide vacuum for a conventional brake system. This is the situation in many diesel-powered vehicles. Diesel engines have no throttling and require a supplemental vacuum for conventional brake systems. A zero drag brake system both eliminates brake drag and avoids the need for a supplemental vacuum pump.

d) Secondary Axle Disconnect (SAX)

All-wheel drive (AWD) and four-wheel drive (4WD) vehicles provide improved traction by delivering torque to the front and rear axles, rather than just one axle. When a second axle is rotating, it tends to consume more energy because of additional losses related to lubricant

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

churning, seal friction, bearing friction, and gear train inefficiencies.^{1456,1457} Some of these losses may be reduced by providing a secondary axle disconnect function that disconnects one of the axles when driving conditions do not call for torque to be delivered to both.

The terms AWD and 4WD are often used interchangeably, although they have also developed a colloquial distinction, and are two separate systems. The term AWD has come to be associated with light-duty passenger vehicles providing variable operation of one or both axles on ordinary roads. The term 4WD is often associated with larger truck-based vehicle platforms providing a locked driveline configuration and/or a low range gearing meant primarily for off-road use.

Many 4WD vehicles provide for a single-axle (or two-wheel) drive mode that may be manually selected by the user. In this mode, a primary axle (usually the rear axle) will be powered, while the other axle (known as the secondary axle) is not. However, even though the secondary axle and associated driveline components are not receiving engine power, they are still connected to the non-driven wheels and will rotate when the vehicle is in motion. This unnecessary rotation consumes energy,¹⁴⁵⁸ and leads to increased fuel consumption and CO₂ emissions that could be avoided if the secondary axle components were completely disconnected and not rotating.

Light-duty AWD systems are often designed to divide variably torque between the front and rear axles in normal driving to optimize traction and handling in response to driving conditions. However, even when the secondary axle is not necessary for enhanced traction or handling, in traditional AWD systems it typically remains engaged with the driveline and continues to generate losses that could be avoided if the axle was instead disconnected. The SAX technology observed in the marketplace disengages one axle (typically the rear axle) for 2WD operation, but detects changes in driving conditions and automatically engages AWD mode when it is necessary. The operation in 2WD can result in reduced fuel consumption. For example, Chrysler has estimated the secondary axle disconnect feature in the Jeep Cherokee reduces friction and drag attributable to the secondary axle by 80% when in disconnect mode.¹⁴⁵⁹

e) Analysis Fleet Assignments for Other Vehicle Technologies

The agencies described in the PRIA that the aforementioned technologies have been applied, to some extent, in the MY 2016 fleet. However, these technologies are difficult to observe and assign to the analysis fleet, and the agencies relied heavily on industry engagement and feedback to assign the technologies properly to the NPRM analysis fleet vehicles. In the

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NPRM, the agencies noted that the Draft TAR analysis did not properly account for the presence of these technologies in the analysis fleet, and far too few were assigned. Accordingly, the NPRM analysis reflected higher EPS and IACC application rates than the Draft TAR analysis.

The agencies received a handful of comments stating that the additional technologies were incorrectly applied to the analysis fleet. ICCT stated that the inclusion of EPS, IACC, and LDB in the analysis fleet was unsubstantiated, and removed the technologies from potential use during the subsequent simulated years.¹⁴⁶⁰ ACEEE commented that IACC should not have been applied to certain vehicles in the analysis fleet because those vehicles do not in actuality display the fuel consumption reduction that would confirm the presence of these additional technologies.¹⁴⁶¹ In addition, ACEEE commented that the CAFE model assumes significant baseline SAX penetration that they could not corroborate from Ford F-150 product information brochures.¹⁴⁶² HDS compared the available levels of IACC improvements from the Draft TAR to the NPRM analysis, noting that the NPRM only employed one level of improved accessory technologies.¹⁴⁶³ HDS stated that this implied the effectiveness of what was previously considered IACC1 (the first level of IACC technology improvement available in the Draft TAR) was completely used up in the 2016 analysis fleet for this rule.

As the agencies stated in the PRIA, in part because of the difficulty in observing EPS, IACC, LDB, and SAX on actual vehicles, far too few of those technologies were assigned to vehicles in the Draft TAR analysis fleets. For the final rule, each vehicle in the MY 2017 analysis fleet was studied using confidential and publicly available information to determine whether, as commenters suggested, the agencies had improperly applied any of these additional vehicle technologies. This resulted in some adjustments in the application of the technologies in the analysis fleet. In regard to ACEEE's comment on SAX penetration in the analysis fleet, for the NPRM and final rule analysis, the agencies considered all 4WD vehicles to have the capability manually to disconnect either the front or rear wheel axle and associated rotating components, thus shifting to a 2WD mode. When 4WD operation is required for safety and utility, the consumer can enable this feature. As stated above, this capacity to shift between 2WD and 4WD modes is another form of SAX. For AWD vehicles, publicly available manufacturer information was reviewed to identify the specific vehicles that have SAX technology. Based on market observations and feedback from OEMs, the entire analysis fleet for NPRM and the final rule was considered to have a basic level of improved accessories (comparable to what Draft TAR referred to as IACC1). The application of IACC in the NPRM and final rule analysis fleets represents further improvements to accessories such as electric water pumps and higher efficiency alternators with mild regeneration capacity.

The following distribution of technologies in the analysis fleet from the NPRM to the final rule analysis shows a slight decrease in the portion of total vehicles produced that have EPS and IACC, a very slight increase in the portion of total vehicle production that have LDB, and a slight increase in the portion of 4WD/AWD vehicles with SAX technology.

Figure II-1546 - Distribution of Technologies in Analysis Fleet Production

f) *Effectiveness Estimates for Other Vehicle Technologies*

The effectiveness estimates for these four technologies rely on previous work published as part of the rulemaking process, both for the 2012 rule for MYs 2017-2025 and the Draft TAR. The effectiveness values are unchanged from the Draft TAR.

The effectiveness of both EPS and EHPS is derived from the decoupling of the pump from the crankshaft, and is considered to be practically the same for both. Thus, a single effectiveness value is assigned to all vehicles in the analysis fleet that possess either EPS or EHPS, and the “EPS” designation is applied.

For the Draft TAR analysis, two levels of IACC were offered as a technology path (a low improvement level and a high improvement level). Since much of the market has incorporated some of these technologies in the baseline MY 2016 and 2017 fleets, the NPRM and final rule analyses assumed all vehicles have incorporated what was previously the low level, so only the high level remained as an option for vehicles. The figure above shows the distribution of IACC

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

for NPRM and FRM, which is the equivalent type of technology as the high-level IACC in the DRAFT TAR.

The NPRM analysis carried forward work on the effectiveness of SAX systems conducted in the Draft TAR and EPA Proposed Determination. This work involved gathering information by monitoring press reports, holding meetings with suppliers and OEMs, and attending industry technical conferences. The resulting effectiveness estimates used in the Draft TAR, NPRM, and this final rule are shown below.

Table II-36109 - Fuel Consumption Improvement Values for Other Vehicle Technologies

NPRM / Final Rule Fuel Consumption Improvements				
Tech Class	LDB	EPS	IACC	SAX

PickupHT				

g) *Cost Estimates and Learning Rates for Other Vehicle Technologies*

The cost estimates for these technologies rely on previous work published as part of the rulemaking process, both for the 2012 rule for MYs 2017-2027 and the Draft TAR. The cost values are from the same sources as the Draft TAR and were updated to 2016 dollars for the NPRM and 2018 dollars for the final rule analysis. Learning rates for these technologies are also unchanged since the NPRM, and can be seen in Section [6.B.4.d.4. Cost Learning as Applied in the CAFE Model].

CARB noted that the IACC costs in tables 6-32 and 6-33 of the PRIA did not align with the Technologies central analysis input file.¹⁴⁶⁴ HDS commented, as part of its comparison of IACC penetration in the analysis fleet from the Draft TAR to NPRM, that IACC costs were

¹⁴⁶⁴ CARB, Docket No. NHTSA-2018-0067-12428, at 21.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

based on the difference between IACC1 and IACC2 costs and this appeared to be inconsistent with the cost of accessory electrification which is more expensive.¹⁴⁶⁵

In the PRIA, the cost of IACC was reported in some tables as an absolute cost (the cost of adding IACC to a base vehicle), while the NPRM Technologies central analysis input file showed IACC cost incremental to EPS. This was necessary in the model input file because the accounting method of the NPRM CAFE model utilized incremental costs. In contrast, a change in the CAFE model accounting method for this final rule allows all costs in the input file to be reported as absolute costs, incremental to a base vehicle. It was assumed that EPS must be present on a vehicle in order for it to adopt IACC, and as such the cost of IACC includes the cost of EPS. For further detail on the use of absolute costs in place of incremental costs, see Section [QVI.C.7.g](#)). Although HDS commented that accessory electrification has a higher cost than what is being used in the analysis, no specific additional input was given; the cost of IACC, as was done for Draft TAR (where it was referred to as IACC2), was taken from the 2015 NAS Report.¹⁴⁶⁶

[Table II-37](#)~~Table VI-71~~ below shows the absolute costs for these technologies for select model years. The FRM Technologies central analysis input file shows the costs for all model years.

Table II-~~37~~[37+10](#) - Final Rule Absolute Costs for Other Vehicle Technologies, including Learning Effects and Retail Price Equivalent (2018\$)

Technology	2017	2021	2025	2029

¹⁴⁶⁶ National Research Council. 2015. Cost, Effectiveness, and Deployment of Fuel Economy Technologies for Light-Duty Vehicles. Washington, DC – The National Academies Press, Table 8A.2a, available at <https://www.nap.edu/catalog/21744/cost-effectiveness-and-deployment-of-fuel-economy-technologies-for-light-duty-vehicles>.

8. Simulating Off-Cycle and A/C Efficiency Technology Adjustments

Off-cycle and air conditioning (A/C) efficiency technologies can provide fuel economy improvements in real-world vehicle operation, but that benefit cannot be adequately captured by the 2-cycle test procedures used to demonstrate compliance with fuel economy and CO₂ emissions standards.¹⁴⁶⁷ Off-cycle technologies include technologies like high efficiency alternators and high efficiency exterior lighting.¹⁴⁶⁸ A/C efficiency technologies operate mainly by reducing the operation of the compressor, which pumps A/C refrigerant around the system loop. The less the compressor operates or the more efficiently it operates, the less load the compressor places on the engine, resulting in better fuel efficiency and lower CO₂ emissions.

Vehicle manufacturers have the option to generate credits for off-cycle technologies and improved A/C systems under the EPA's CO₂ program and receive a fuel consumption improvement value (FCIV) equal to the value of the benefit not captured on the 2-cycle test under NHTSA's CAFE program. The FCIV is not a credit in the NHTSA CAFE program, but the FCIVs increase the reported fuel economy of a manufacturer's fleet, which is used to determine compliance. EPA applies FCIVs during determination of a fleet's final average fuel economy reported to NHTSA.¹⁴⁶⁹ FCIVs are only calculated and applied at a fleet level for a manufacturer and are based on the volume of the manufacturer's fleet that contain qualifying technologies.¹⁴⁷⁰

As discussed further in Section [Compliance Issues that Affect Both the CO₂ and CAFE Programs], three pathways can be used to determine the value of A/C efficiency and off-cycle adjustments. First, manufacturers can use a predetermined list or "menu" of credit values established by EPA for specific off-cycle technologies.¹⁴⁷¹ Second, manufacturers can use 5-cycle testing to demonstrate and justify off-cycle CO₂ credits;¹⁴⁷² the additional tests allow emission benefits to be demonstrated over some elements of real-world driving not captured by the 2-cycle compliance tests, including high speeds, rapid accelerations, and cold temperatures.

¹⁴⁶⁷ See 49 U.S.C. 32904(c) ("The Administrator shall measure fuel economy for each model and calculate average fuel economy for a manufacturer under testing and calculation procedures prescribed by the Administrator. . . . the Administrator shall use the same procedures for passenger automobiles the Administrator used for model year 1975 (weighted 55 percent urban cycle and 45 percent highway cycle), or procedures that give comparable results.").

¹⁴⁶⁸ See 83 FR 43057. A partial list of off-cycle technologies is included in Tables II-21 and II-22 of the NPRM.

¹⁴⁶⁹ 49 U.S.C. 32904(c)-(e). EPCA granted EPA authority to establish fuel economy testing and calculation procedures. See Section [Section P09] for more information.

¹⁴⁷⁰ 40 CFR 600.510-12(c)

¹⁴⁷¹ See 40 CFR 86.1869-12(b). The Technical Support Document (TSD) for the 2012 final rule for MYs 2017 and beyond provides technology examples and guidance with respect to the potential pathways to achieve the desired physical impact of a specific off-cycle technology from the menu and provides the foundation for the analysis justifying the credits provided by the menu. The expectation is that manufacturers will use the information in the TSD to design and implement off-cycle technologies that meet or exceed those expectations in order to achieve the real-world benefits of off-cycle technologies from the menu.

¹⁴⁷² See 40 CFR 86.1869-12(c). EPA proposed a correction for the 5-cycle pathway in a separate technical amendments rulemaking. See 83 FR 49344 (Oct. 1, 2019). EPA is not approving credits based on the 5-cycle pathway pending the finalization of the technical amendments rule.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Third, manufacturers can seek EPA approval, through a notice and comment process, to use an alternative methodology other than the menu or 5-cycle methodology for determining the off-cycle technology improvement values.¹⁴⁷³

The agencies have been collecting data on the application of these technologies since implementing the programs.¹⁴⁷⁴ Most manufacturers are generating A/C efficiency and off-cycle credits; in MY 2017, 15 manufacturers generated A/C efficiency credits and 15 manufacturers generated off-cycle credits, through the level of deployment varies by manufacturer.¹⁴⁷⁵

a) A/C and Off-Cycle Effectiveness Modeling

The NPRM analysis used the off-cycle FCIVs and credits earned by each manufacturer in MY 2016 and carried these forward at the same levels for future years for the CO₂ analysis and beginning in MY 2017 for the CAFE analysis. The 2016 values for off-cycle FCIVs for each manufacturer and fleet, denominated in grams CO₂ per mile,¹⁴⁷⁶ are provided in [Table II-38Table VI-63](#).¹⁴⁷⁷ Additional off-cycle FCIVs were added in future years if a manufacturer applied a technology that was explicitly simulated in the analysis and also was an off-cycle technology listed on the predefined menu.¹⁴⁷⁸ Technologies explicitly simulated in the analysis that are also on the off-cycle menu include start-stop systems that reduce fuel consumption during idle and active grille shutters that improve aerodynamic drag at highway speeds, among others. Any off-cycle adjustments that accrued as the result of applying these technologies were calculated dynamically in each model year the technology was applied, with adjustments accumulating up to the 10 g/mi cap. As a practical matter, most of the adjustments for which manufacturers can claim off-cycle FCIVs exist outside of the CAFE model technology tree so the off-cycle menu cap was rarely reached for the NPRM analysis.

The agencies sought comment on both the A/C and off-cycle data that was used for the NPRM analysis as well as the assumptions for applying those technologies.

¹⁴⁷³ See 40 CFR 86.1869-12(d).

¹⁴⁷⁴ See 77 FR at 62832, 62839 (Oct. 15, 2012). EPA introduced A/C and off-cycle technology credits for the CO₂ program in the MYs 2012-2016 rule and revised the program in the MY 2017-2025 rule and NHTSA adopted equivalent provisions for MYs 2017 and later in the MY 2017-2025 rule.

¹⁴⁷⁵ The 2018 EPA Automotive Trends Report, EPA-420-R-19-002, March 2019 at Chapter 5.B., Figures 5.10 and 5.11.

¹⁴⁷⁶ For the purpose of estimating their contribution to CAFE compliance, the grams CO₂/mile values in [Table II-38Table I-1](#) are converted to gallons/mile and applied to a manufacturer's 2-cycle CAFE performance. When calculating compliance with EPA's CO₂ program, there is no conversion necessary (as standards are also denominated in grams/mile).

¹⁴⁷⁷ 2016 GHG Manufacturer Performance Report. EPA-420-R-18-002. January 2018. <https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P100TGIA.pdf>. Last Accessed Nov. 14, 2019.

Universally, stakeholders believed the application of off-cycle adjustments in the analysis was too conservative. Stakeholders believed the A/C and off-cycle technologies would be rapidly deployed and manufacturers would reach the cap values within the rulemaking timeframe.

The Institute for Policy Integrity (IPI) questioned the position the agencies assumed in the NPRM analysis, and suggested the agencies “assume that manufacturers will efficiently deploy all cost-saving offset opportunities, especially in the face of increasingly stringent standards.”¹⁴⁸⁰

¹⁴⁷⁹ See 83 FR 43159-60 (“...this analysis uses the off-cycle credits submitted by each manufacturer for MY 2017 compliance and carries these forward to future years with a few exceptions.”).

¹⁴⁸⁰ Comments from Institute from Policy Integrity, Attachment 1, NPRM Docket No. NHTSA-2018-0067-12213, at 20-21.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

ICCT stated “far greater use of the off-cycle provisions will occur by 2025” and emphasized that off-cycle technologies are “highly cost-effective and being deployed in greater sales penetrations than many of the test-cycle efficiency technologies that the agencies are analyzing.”¹⁴⁸¹ ICCT supported manufacturers maximizing the use of off-cycle technologies, and supported the analysis estimating “fleetwide off-cycle credit use at over 10 g/mile by 2020,” and further suggested fleetwide achievement of 15 g/mile by 2025.¹⁴⁸²

FCA, General Motors and the Auto Alliance all provided similar observations, stating “[m]anufacturers have rapidly deployed technology in response to this all new regulatory mechanism.” Each of the commenters provided support for an argument of rapid off-cycle technology adoption, stating “[i]n the MY2021-2026 timeframe of the proposed rule, it is likely that manufacturers will hit the existing 10 g/mi cap.”¹⁴⁸³

The DENSO Corporation further supported the increased use of off-cycle technologies, commenting that “[a]vailable data on OEM off-cycle technology credit utilization within the past few years demonstrates that the use of off-cycle technologies is expected to grow—particularly technologies on the credit menus.”¹⁴⁸⁴

However, Toyota Motors North America asked for constraints on considerations of off-cycle technology in the analysis.¹⁴⁸⁵ Toyota expressed concern for over-reliance on off-cycle technologies to provide flexibilities for compliance, as “most of the technologies provide little tangible value proposition for customers.” In additional comments, Toyota repeated the concern noting, “most of these technologies lack consumer demand.” Finally, Toyota specifically cautioned against overusing off-cycle technologies in the analysis, stating “[t]he suggested pursuit of maximum credits overlooks the associated costs and market acceptance challenge for certain off-cycle technologies.” Toyota listed costs versus risk of customer acceptance and agency approval as factors that “introduce a high level of uncertainty for an auto manufacturer’s planning and make investments in off-cycle technologies risky and less appealing.”

¹⁴⁸¹ Comments from ICCT, Attachment 1, NPRM Docket No. NHTSA-2018-0067-11741, at 140 – 141.

¹⁴⁸² Note there is a regulatory “cap” on menu technologies of 10 g/mi (see [Section P09] for further discussion of the cap), however a manufacturer can receive additional off-cycle credit/FCIV by using the pathways described above to petition for off-menu technologies. ICCT’s comment suggests that manufacturers will reach the regulatory menu cap and apply additional technologies to get an additional 5 g/mi credit above the menu cap.

¹⁴⁸³ Comments from Automotive Alliance, Appendix 1, NPRM Docket No. NHTSA-2018-0067-12073, at 92; Comments from Fiat Chrysler Automobiles, Attachment 1, NPRM Docket No. NHTSA-2018-0067-11943, at 8; Comments from General Motors, Appendix 4 – Comments to Technical Issues, NPRM Docket No. NHTSA-2018-0067-11858, at 1.

¹⁴⁸⁴ Comments from DENSO Corporation, Attachment 1, NPRM Docket No. NHTSA-2018-0067-11880, at 6.

¹⁴⁸⁵ Comments from Toyota Motors North America, Attachment 1, NHTSA Docket No. NHTSA-2018-0067-130798, at 9-10; Supplemental Comments from Toyota Motors North America, Attachment 1, NHTSA Docket No. NHTSA-2018-0067-12150, at 24; Supplemental Comments from Toyota Motors North America, Attachment 1, NHTSA Docket No. NHTSA-2018-0067-12376, at 4-5.

After carefully considering the comments, the agencies agree that A/C and off-cycle technologies are likely to be more broadly applied by manufacturers within the rulemaking timeframe. The final rule analysis has been updated to reflect an increased application of the technologies. Similar to the NPRM, the final rule analysis used the A/C and off-cycle FCIVs earned by each manufacturer in the baseline fleet (MY 2017 for the final rule analysis) as a starting point. However, the final rule analysis increased these values in subsequent model years. In addition to the dynamic application of off-cycle FCIVs, as in the NPRM, each manufacturer's fleet FCIVs were increased by extrapolating the manufacturers' historical rate of FCIV application through 2017.¹⁴⁸⁶ In line with most commenters, the agencies increased the FCIVs for each manufacturer such that the maximum value of 10 g/mi will be reached by MY 2023. For manufacturers who did not reach maximum values prior to 2023 through data extrapolation, a linear increase to the cap was assumed. The agencies believe this approach balances a greater application of FCIV technologies across the fleet, while avoiding uncertain over-reliance on flexibilities for the analysis.

The agencies disagreed with the proposal to model the application of 15 g/mi of FCIVs universally in the rulemaking timeframe. Based on historical data and industry comments from both manufacturers and suppliers, the agencies expect there will be an increase in off-cycle technology application. However, there are two issues with assuming manufacturers will exceed the existing off-cycle caps. First, only a few manufacturers approached the cap limit in MY 2018, and the fleet average menu credit was 4.7 grams/mile, less than half the cap value.¹⁴⁸⁷ Second, new off-cycle technologies may address the same inefficiencies as menu technologies, rather than work in conjunction. Accordingly, the agencies believe there is a reasonable basis for assuming manufacturers could, and would only achieve 10 g/mi on average by MY 2023, and used that assumption for the final rule analysis.

Table II-39Table VI-64 shows passenger car values for FCIVs and Table II-40Table VI-74 shows light truck values for FCIVs applied for the final rule analysis.

b) A/C Efficiency, A/C Leakage and Off-Cycle Costs

As discussed above, the only A/C efficiency and off-cycle technologies applied dynamically in the NPRM analysis were explicitly simulated technologies like stop-start systems and active aerodynamic technologies. The NPRM analysis fully accounted for both the effectiveness and cost of these technologies and therefore separate cost accounting was not needed. For example, when stop-start or active aerodynamics technology was added by the model to a vehicle, the corresponding off-cycle FCIVs were applied and the technology costs were captured the same as every other technology on the decision trees.

For the final rule analysis, A/C and off-cycle technologies are applied independently of the decision trees using the extrapolated values, so it is necessary to account for the costs of those technologies independently. ~~Table II-41~~ ~~Table VI-75~~ shows the costs used for A/C and off-cycle FCIVs the final rule analysis. The costs are shown in dollars per gram of CO₂ per mile (\$ per g/mile). The A/C costs and off-cycle technology costs are the same costs used in the EPA Proposed Determination and described in the EPA Proposed Determination TSD.¹⁴⁸⁸

D. Impacts that result from simulating manufacturer compliance with regulatory alternatives

1. Simulating economic impacts of regulatory alternatives

a) *What economic impacts occur when vehicle manufacturers comply with different CAFE and CO₂ standards?*

(1) *The NPRM framework for analyzing economic impacts*

In the proposed rule, the agencies noted the importance of identifying the mechanisms by which vehicle manufacturers' compliance with different CAFE and CO₂ standards generated impacts on manufacturers, owners of new and used vehicles, and the remainder of the U.S. The agencies organized the analysis of alternative standards using a framework that clarified the economic impacts on vehicle producers, illustrated how costs were transmitted to buyers of new vehicles, highlighted the collateral economic effects on owners of used vehicles, and identified how these responses created various indirect costs and benefits. Throughout the analysis, the agencies stressed the distinction between the proposal's economic consequences for private businesses and households, and its "external" economic impacts—those ultimately borne by the rest of the U.S. economy.

To clarify the framework used in the proposal, the agencies used [Table II-42](#) ~~Table VI-122~~ below (which is based on Tables II-25 to II-28 from the NPRM)¹⁴⁸⁹ to report costs and benefits and to trace how they pass through the economy. As the table shows, the economic impacts of standards initially fall on vehicle manufactures, but ultimately are borne by consumers who purchase and drive new models. Smaller, indirect economic effects of the

¹⁴⁸⁹ See 83 FR at 43062-66.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

proposal would be borne by owners of used cars and light trucks (vehicles produced during model years prior to those affected by the proposal, but still in use) as well as by the general public and government agencies. On balance, the agencies projected that most of the proposal's economic effects would fall on private businesses and households, with the remainder of the U.S. economy bearing much smaller impacts.

Table II-~~42+15~~ - Benefits and Costs Resulting from Proposed CAFE Standards

Line	Affected Party	Source	Private Benefits and (Costs)
1	Vehicle Manufacturers	CAFE model	Savings in technology costs to increase fuel economy
2			Reduced fine payments for non-compliance
3		assumed = -(1+2)	Net loss in revenue from lower vehicle prices
4		net = 1+2+3	Net benefits to manufacturers
5	New Vehicle Buyers	assumed = 3	Lower purchase prices for new vehicles
6		CAFE model	Reduced injuries and fatalities from higher vehicle weight
7			Higher fuel costs from lower fuel economy (measured using retail fuel prices)
8			Inconvenience from more frequent refueling
9			Lost mobility benefits from reduced driving
10		net = 5+6+7+8+9	Net benefits to new vehicle buyers
11	Used Vehicle Owners	CAFE model	Reduced costs for injuries and property damage costs from driving in used vehicles
12	All Private Parties	net = 4+10+11	Net private benefits
Line	Affected Party	Source	External Benefits and (Costs)
13	Rest of U.S. Economy	CAFE Model	Increase in climate damages from added CO ₂ Emissions
14			Increase in health damages from added emissions of air pollutants
15			Increase in economic externalities from added petroleum use
16			Reduction in civil penalty revenue
17			Reduction in external costs from lower vehicle use
18			Increase in Fuel Tax Revenues
19		net = 13+14+15+16+17+18	Net external benefits
Line	Affected Party	Source	Economy-Wide Benefits and (Costs)
20	Entire U.S. Economy	total = 1+2+5+6+11+17+18	Total benefits

Line	Affected Party	Source	Private Benefits and (Costs)
21		total = 3+7+8+9+13+14+15+16	Total costs
22		net = 20+21 (also =12+19)	Net Benefits

More specifically, the agencies' analysis showed that the proposal would initially have saved manufacturers the costs of adding the technologies that would otherwise have been necessary to enable their new cars and light trucks to comply with the baseline fuel economy and CO₂ emissions regulations, with the estimated dollar value of those savings shown in line 1 of [Table II-42](#) ~~Table VI-122~~. The proposal also enabled some manufacturers to make lower civil penalty payments for failing to comply with the more demanding standards that were supplanted (line 2), although these savings would have been exactly offset by lower civil penalty revenue to the Federal Government (line 16). The analysis assumed that manufacturers would have the ability, in a competitive market, to pass their savings in technology costs and any reduction in civil penalties paid on to buyers, by charging lower prices for new vehicles. Although lower prices reduced their revenues (line 3), on balance, their savings in compliance costs, reduced civil penalty payments, and lower sales revenue were assumed to leave manufacturers financially unaffected (shown by the zero entry in line 4 of the table).

Under the proposal, the analysis showed that buyers of new cars and light trucks benefited directly from those vehicles' lower purchase prices and financing costs (line 5). They also avoided the increased risk of crash-related injuries that would have resulted from reductions in the weight of some new models, as manufacturers attempted to improve fuel economy to comply with the baseline standards. The economic value of this reduction in risk represented an additional benefit from the proposal to reducing the stringency of the standards vis-à-vis the baseline (line 6).

At the same time, however, the lower fuel economy that some new cars and light trucks were expected to offer with less stringent standards in place would have imposed various additional costs on their buyers and users. Drivers experienced higher fuel costs as a consequence of new vehicles' increased fuel consumption (line 7), as well as the added time and inconvenience of having to make more frequent refueling stops required by reduced driving range (line 8). They also forfeited some mobility benefits as they drove newly-purchased cars and light trucks less in response to their higher fuel costs (line 9). On balance, the agencies' analysis of the proposal showed that buyers of new cars and light trucks produced during the model years it affected would experience significant economic benefits (line 10).

A novel feature of the agencies' evaluation of the proposal showed that lowering prices for new cars and light trucks, some owners of used vehicles retired them from service earlier than they otherwise would have done. In combination with increased sales of new models, this transferred some driving that would have occurred with used cars and light trucks to newer and safer models, thus reducing the total costs of fatalities and injuries sustained in motor vehicle

crashes.¹⁴⁹⁰ In the proposal, this reduction in injury risks provided benefits to owners and drivers of older cars and light trucks that had not been recognized or quantified in its analyses of previous CAFE and CO₂ standards (line 11).

Table II-42 Table VI-122 also showed that the changes in fuel consumption and vehicle use resulting from the proposal would in turn generate both benefits and costs to the remainder of the U.S. economy. The analysis described these as “external” effects, in the sense that they were by-products of households’ choices among new vehicle models, decisions about keeping older cars and light trucks in service, and allocations of driving across the fleet that were experienced broadly throughout the U.S. economy, rather than by the individuals making such decisions. The largest of these was additional refining and consumption of petroleum-based fuel and the associated increases in emissions of carbon dioxide and other gases, which were projected to increase the cost of economic damages inflicted on the U.S. economy by future changes in the global climate (line 13). Added fuel production and use under the proposal also led to higher emissions of localized air pollutants, and the resulting increase in the U.S. population’s exposure and its adverse effects on health imposed additional external costs (line 14).

Increased consumption of petroleum-derived fuel also imposed higher external costs on the U.S. economy, in the form of potential losses in economic output and costs to businesses and households for adjusting to any sudden changes in energy prices (line 15 of the table). Reduced driving by buyers of new cars and light trucks in response to their higher operating costs also reduced the external costs from their contributions to traffic delays and noise, benefits that were expected to be experienced throughout the U.S. economy (line 17). Finally, some of the higher fuel costs to buyers of new cars and light trucks will consist of increased fuel taxes; this increase in revenue was projected to enable Federal and State government agencies to improve upkeep of roads and highways, fund increases in other services, or reduce other tax burdens (line 18).¹⁴⁹¹

The net economic effect (line 22) of the proposal consisted of the benefits and costs imposed directly on car and light truck manufacturers, accompanying indirect effects on buyers of new vehicles and owners of used ones, external costs driving decisions generated throughout the U.S. economy, and changes in revenue to government agencies. The agencies’ organization was intended to convey the causal connections among these impacts, by highlighting how the proposed change in fuel economy standards faced by manufacturers would set in motion the sequence of behavioral responses that determined its economy-wide costs and benefits. This contrasted with the way benefits and costs of previous proposals to establish CAFE and CO₂ standards were analyzed and presented, which obscured their sequence and causal connections.

¹⁴⁹⁰ This improvement in safety resulted from the fact that cars and light trucks have become progressively more protective in crashes over time (and also slightly less prone to certain types of crashes, such as rollovers). Thus, shifting some travel from older to newer models reduced injuries and damages sustained by drivers and passengers because they were traveling in inherently safer vehicles, rather than because of changes to driver risk profiles.

¹⁴⁹¹ In some States, levies on gasoline include both general sales taxes as well as excise taxes, and not all proceeds are dedicated to transportation purposes.

In those previous analyses, most economic effects other than manufacturers' costs to comply with proposed standards and anticipated changes in fuel consumption were grouped together and reported as "co-benefits." This obscured how these various consequences arose from the proposed standards, providing no information about who would ultimately experience the costs of complying with the standards, or who would experience their direct and indirect benefits. In contrast, the recent analysis spelled out how each category of benefits and costs resulted from the proposed change in standards, identified the mechanisms that translated direct economic impacts into indirect costs and benefits, and distinguished between those arising from changes in fuel consumption, and safety consequences of changes in vehicle use. The proposal's framework also clarified who would bear each category of impacts, distinguishing between the proposal's economic impacts on private actors—vehicle manufacturers, new car and light truck buyers, and owners of used vehicles—and the external economic consequences for the general public and government agencies that stem indirectly from such private impacts.

(2) *Final rule framework*

While the agencies received several comments about which economic effects are included in the analysis, the agencies received no comments about the specific structure of the framework. Substantive comments about individual effects are addressed over the next several sections.

The agencies have expanded the accounting framework for benefits and costs shown in [Table II-42](#)~~Table VI-122~~ above to include two additional entries, as well as to distinguish financial impacts on government agencies from externalities borne broadly across the remainder of the U.S. economy. The revised accounting framework for costs and benefits is shown in [Table II-43](#)~~Table VI-123~~, below. Line 6 of the revised table reports the change in consumer surplus experienced by buyers of new cars and light trucks when prices and sales of those vehicles adjust in response to changes in CAFE and CO₂ standards. The gain in consumer surplus that occurs when production costs and prices for vehicles fall and sales increase in response represents a benefit to buyers, while any loss in consumer surplus that occurs when more stringent standards increase costs and prices and cause sales to decline appears as a loss to new car and light truck buyers.

Line 7 of [Table II-43](#)~~Table VI-123~~ reports the estimated value of changes to attributes of new cars and light trucks other than fuel economy that their manufacturers make to comply with changes in CAFE and CO₂ standards. In the case where standards are less stringent, manufacturers are able to employ many of the same resources they would have deployed to increase fuel economy for the alternative purpose of improving other attributes of vehicles that their potential buyers value more highly than the forgone improvements in fuel economy. This response provides an additional benefit to purchasers of new cars and light trucks that was not recognized in the agencies' analysis of the proposal, but is included in the analysis of this final rule. Of course, if CAFE and CO₂ standards are made more stringent, manufacturers employ those technologies to increase fuel economy, thus sacrificing potential improvements in competing attributes—those that entail tradeoffs with higher fuel economy—and the value of improvements in those other attributes that is sacrificed or forgone represents an opportunity cost

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

to those buyers. This implicit opportunity cost is analyzed in a sensitivity analysis and is not included in the primary analysis.

Finally, the agencies revised the framework for reporting costs and benefits of changes in CAFE and CO₂ standards to identify government agencies separately from the entry previously labeled “Rest of U.S Economy.” This minor revision is intended to distinguish more clearly between changes in external costs imposed by externalities that result from fuel production and use, and the revenue effects on government agencies from changes in tax and civil penalty payments. While both effects ultimately result from manufacturers’ compliance with revised standards and the resulting changes in fuel consumption, externalities represent real economic costs; in contrast, changes in tax revenues received by government agencies are financial transfers, whose offsetting effects on manufacturers and vehicle buyers are also recognized elsewhere in the accounting framework.

Table II-4346 - Benefits and Costs of Final CAFE and CO₂ Standards

Line	Affected Party	Source	Private Benefits and (Costs)
1	Vehicle Manufacturers	CAFE model	Savings in technology costs to increase fuel economy
2			Reduced penalties for non-compliance
3		assumed = -(1+2)	Net loss in revenue from lower vehicle prices
4		net = 1+2+3	Net benefits to manufacturers
5	New Vehicle Buyers	assumed = 3	Lower purchase prices for new vehicles
6		CAFE model	Gain in consumer surplus from lower vehicle prices
7			Im (sensitivity analysis case only)
8			Reduced injuries and fatalities from higher vehicle weight
9			Higher fuel costs from lower fuel economy (measured using retail fuel prices)
10			Time and inconvenience from more frequent refueling
11			Loss in mobility benefits from reduced driving
12		net = 5+6+8+9+10+11	Net benefits to new vehicle buyers
13	Used Vehicle Owners	CAFE model	Reduced costs for injuries and property damage costs from driving in used vehicles
14	All Private Parties	net = 4+12+13	Net private benefits
15	Government agencies	CAFE Model	Reduction in revenue from civil penalties
16			Increase in fuel tax revenue
17		Net=15+16	Net effect on government agency revenue
18		CAFE Model	Increase in climate damages from added CO ₂ Emissions

25		net = 21+22 (also =14+17+22)	Net Benefits

b) Economic Assumptions

(1) Macroeconomic assumptions that affect the agencies' analysis

As the proposed rule noted, the more comprehensive economic impact analysis of CAFE and CO₂ included in this rulemaking requires a more detailed and explicit explanation of the macroeconomic context in which regulatory alternatives are evaluated. The agencies continued to rely on projections of future fuel prices to evaluate manufacturers' use of fuel-saving technologies, the resulting changes in fuel consumption, and various other benefits. Furthermore, the agencies expanded the scope of their analysis to include projecting future sales of new cars and light trucks, as well as the retirement of used vehicles under each regulatory alternative. In addition to projections of future fuel prices, constructing these forecasts requires explicit projections of macroeconomic variables, including U.S. Gross Domestic Product (GDP), labor force participation (the number of persons employed or actively seeking employment), and bellwether interest rates, which are likely to vary according to roughly the same pattern as interest rates on new car loans.

The analysis presented in the proposal as well as the accompanying RIA and EIS employed forecasts of future fuel prices developed by the agencies using the U.S. Energy Information Administration's (EIA's) National Energy Model System (NEMS). An agency within the U.S. Department of Energy (DOE), EIA collects, analyzes, and disseminates independent and impartial energy information to promote sound policymaking, efficient markets, and public understanding of energy and its interaction with the economy and the environment. EIA uses NEMS to produce its Annual Energy Outlook (AEO), which presents forecasts of future fuel prices, among many other energy-related variables. AEO projections of energy prices and other variables are not intended as predictions of what will happen; rather, they are projections of the likely course of these variables that reflect their past relationships, specific assumptions about future developments in global energy markets, and the forecasting

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

methodologies incorporated in NEMS. Each AEO includes a “Reference” case as well as a range of alternative scenarios that each incorporate somewhat different assumptions from those underlying the Reference Case.

For the proposal, the agencies used the AEO2017 version of NEMS, as this was the most current version of the model that was available at the time. Using this version of NEMS, the agencies reevaluated the “Reference,” “Low Oil Price,” and “High Oil Price” cases described in AEO2017, by setting aside their assumption that mandates by California and other States to sell “Zero Emission Vehicles” (ZEVs) would be enforced. The agencies used the resulting modified Reference case fuel prices as inputs to the proposal’s central case results, and used the modified “Low Oil Price” and “High Oil Price” case fuel prices, which were generated using NEMS, as inputs to several of the sensitivity analysis cases that were presented in the proposal. The sensitivity analysis also included a case that applied the Reference case fuel prices from the then recently issued AEO2018, which did not reflect the modification of EIA’s forecasting model to set aside state mandates for ZEV sales.¹⁴⁹²

The analysis supporting the proposed rule simulated the economic impacts of car and light truck manufacturers’ compliance with alternative CAFE and CO₂ standards through model year 2032, and in doing so estimated the number of vehicles originally produced and sold in each model year that would remain in service during each year of their useful lives (assumed to extend for a maximum of 40 years), as well as their usage, fuel consumption, and safety performance. This required the forecasts of macroeconomic variables that affect vehicle sales, use, and retirement rates, which include U.S. Gross Domestic Product (GDP), the size of the domestic labor force, and key interest rates, to extend well beyond calendar year 2050. One of the few sources that provides forecasts of these variables spanning such a long time horizon was the 2017 OASDI Trustees Report from the U.S. Social Security Administration, and the analysis supporting the proposed rule relied on this source for forecasts of these key macroeconomic measures.¹⁴⁹³

(a) Comments on the fuel price forecasts and macroeconomic assumptions used in the NPRM analysis

The agencies received relatively few comments on the projections of fuel prices and macroeconomic variables that were used in their analysis supporting the proposed rule, virtually all of them focused on the fuel price projections the agencies employed. While only one comment questioned the agencies’ use of price projections that rely on EIA’s methodology and assumptions, a few commenters called attention to the unreliability of price projections reported in earlier editions of AEO. Other comments noted the importance of updating projections used

¹⁴⁹² The results of these and other sensitivity analyses were reported in NHTSA and EPA, “Notice of Proposed Rulemaking: The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks,” Federal Register Vol. 83, No. 165, August 24, 2018, Tables Vii-90 to Vii-98, pp. 43353-69.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

to analyze the proposal to reflect more recent developments in energy markets, without necessarily questioning the reliability of EIA's fuel price projections. Several comments emphasized the implications for the agencies' analysis of the wide variation in alternative fuel price projections reported in both EIA's 2017 and 2018 Annual Energy Outlooks, with most stressing the possibility that future prices might be above even those projected in their High Oil Price cases. Only a single comment identified a potential alternative source of fuel price projections, but noted that it was within the range of projections the agencies considered.

One commenter claimed that AEO's projections of fuel prices are "inappropriate" for the agencies to employ in analyzing the consequences of CAFE and CO₂ standards; because EIA "does not speculate on changes in international policy or geopolitics," which contribute to the uncertainty surrounding future prices.¹⁴⁹⁴ However, this commenter did not identify an alternative source for fuel price projections that reflect such considerations; and because projections of fuel prices are a central element in the agencies' evaluation of alternative future standards, the observation that EIA's projections do not incorporate some sources of uncertainty is unhelpful by itself.

Some commenters asserted that by relying on the AEO2017 Reference Case projections of fuel prices in their central analysis of the proposed rule while considering the significantly higher fuel prices projection in the AEO High Oil Price scenario only in the accompanying sensitivity analyses, the agencies inadequately considered the possible effect of higher fuel prices on the estimated economic benefits from alternatives that would have relaxed the augural standards, including the preferred alternative.¹⁴⁹⁵ Surprisingly, none of these comments acknowledged that the fuel price projections reported in the High Oil Price cases accompanying past editions of the Annual Energy Outlook have so far proven to be significantly above actual prices, or that EIA has consistently lowered its fuel price projections in more recent editions of the AEO. In any case, supplemental material included in the NPRM regulatory docket showed that the ranking of regulatory alternatives by their estimated net economic benefits remained unchanged from the central analysis in the sensitivity analysis that substituted the AEO2017 High Oil Price case projection of fuel prices.

None of the commenters who argued that the agencies inadequately considered the possibility of higher fuel prices observed that the agencies' analogous use of lower fuel price projections from the AEO2017 Low Oil Price case only in their sensitivity analyses inadequately considered the possibility that future fuel prices might prove to be *lower* than projected in the AEO2017 Reference Case, and its potential effect on the proposal's estimated benefits. Nor did any of the commenters offer substantive guidance about how the agencies might revise their

¹⁴⁹⁴ NHTSA-2018-0067-11837, Alliance to Save Energy, p. 2 ("EIA takes a transparently conservative approach in modeling future oil prices, and does not speculate on changes in international policy or geopolitics. As a result, their projections are an inappropriate measure of future fuel prices.").

¹⁴⁹⁵ See e.g., Securing America's Future Energy (SAFE), NHTSA-2018-0067-11981, pp. 12 & 30 and Institute for Policy Integrity, NHTSA-2018-0067-12213, p. 31.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

analysis to accord greater emphasis to fuel price projections above (or below) those from the AEO Reference Case.¹⁴⁹⁶

Other comments stressed the fact that EIA's current projections of future fuel prices are significantly lower than those the agencies relied on when they established CAFE standards through model year 2021 and introduced the augural standards for subsequent model years in the rulemaking they conducted in 2012, citing this as support for the agencies' reconsideration of the augural standards in the current rulemaking.¹⁴⁹⁷

One comment compared the range of fuel price projections spanned by the High and Low Oil Price cases from AEO2017 and AEO2018 to the range of future prices spanned by another widely-recognized and relied-upon projection, concluding that the alternative scenarios included in AEO2017 incorporated an even wider range of uncertainty about future prices, and noted that the net economic benefits of the preferred alternative were positive over this entire range of alternative future fuel prices. This same commenter noted that by combining high and low fuel price projections with alternative assumptions about other key economic variables (such as GDP growth) and parameter assumptions (principally payback period), the agencies' sensitivity analyses captured potentially important interactions between uncertainty regarding fuel prices and other key economic inputs.¹⁴⁹⁸

(b) Macroeconomic assumptions used to analyze economic consequences of the final rule

After considering these comments, the agencies have concluded that there is no convincing reason to rely on sources other than EIA's NEMS model to project future energy prices, or to rely on alternatives to the Reference Case scenario in the current edition of AEO as their basis for using NEMS. The agencies agree that the resulting projections will be uncertain, but note that EIA regularly publishes retrospective analyses comparing past Reference case projections to subsequent market price outcomes, thus enabling an assessment of this uncertainty. Although EIA does not identify its Reference case as a "most likely" outcome, in the agencies' judgment that case's design—which assumes future trends are consistent with historical and current market behavior—makes it a reasonable and appropriate basis for

¹⁴⁹⁶ One commenter did refer to guidance to EPA contained in a National Research Council report on incorporating and conveying uncertainty about key inputs directly into that agency's estimates of benefits from reducing air pollution, rather than simply recognizing it in supplemental sensitivity analyses. This was presumably intended as potential guidance to the agencies about how they might do so in their evaluations of fuel economy and CO₂ standards, although that was not stated explicitly. See American Fuel & Petrochemical Manufacturers, NHTSA-2018-0067-12078, p. 19, citing National Research Council (2002), *Estimating the Public Health Benefits of Proposed Air Pollution Regulations*, 2002, available at <https://www.nap.edu/catalog/10511/estimating-the-public-health-benefits-of-proposed-air-pollution-regulations>.

¹⁴⁹⁷ For example, Fiat Chrysler Automobiles (FCA) pointed out that the AEO 2017 Reference Case forecast of gasoline prices through 2025 is approximately 36% lower than that in the AEO 2012 Reference Case, which the agencies relied on in the analysis supporting that earlier rulemaking; see NHTSA-2018-0067-11943, p. 33.

¹⁴⁹⁸ See Alliance of Automobile Manufacturers, NHTSA-2018-0067-1207, p. 108.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

projecting fuel prices to use in the agencies' central analysis of alternative CAFE and CO₂ standards.

The agencies also conclude that the wide range of uncertainty about future petroleum prices encompassed in EIA's "Low Oil Price" and "High Oil Price" cases means that including them in the accompanying sensitivity analyses provides a meaningful basis for assessing the potential economic consequences of future energy prices that prove to be considerably lower or higher than those reflected in the Reference case. Although these alternative cases do not incorporate unbridled speculation regarding hypothetical changes in "international policy or geopolitics," the agencies believe that this restraint means that relying on them produces a more, rather than less, meaningful test of the effect of the inherent uncertainty surrounding projections of fuel prices.

For today's final rule, the agencies have therefore used the AEO2019 version of NEMS to develop projections of future prices for transportation fuels, as this was the most current version available when this analysis was conducted. Using this version of NEMS, the agencies modified EIA's AEO2019 Reference case by (1) setting aside presumed enforcement by California and other States of any mandates to sell "Zero Emission Vehicles" (ZEVs), (2) setting aside post-2020 increases in the stringency of CAFE and CO₂ standards, and (3) modifying inputs regarding battery costs, in order to bring those costs down to levels more consistent with battery cost estimates applied in the CAFE model analysis.¹⁴⁹⁹ All other NEMS inputs used to develop the AEO2019 Reference case were left unchanged in this analysis.

Setting aside enforcement of state mandates to sell ZEVs makes the supporting analysis consistent with the agencies' recent One National Program Action,¹⁵⁰⁰ under which EPA withdrew aspects of a Clean Air Act Preemption waiver previously granted to California, and NHTSA concluded that EPCA expressly and implied preempted State ZEV mandates. Setting aside the post-2020 increase in the stringency of CAFE and CO₂ standards ensures that the fuel prices used in the agencies' analysis are at least as high as those that would prevail under the least stringent regulatory alternative considered, since that alternative produces the highest level of fuel consumption and thus the highest fuel prices.

Figure I-II-16Figure I-41 and Figure I-II-17Figure I-42 below show the resulting modified projections of BEV prices and sales, and compare them to the projections reported in EIA's AEO2019 Reference case. As they illustrate, the combination of these modifications led NEMS to project significantly lower BEV prices and correspondingly higher BEV sales volumes. Figure I-II-18Figure I-43 and Figure I-II-19Figure I-44 show the modified projections of gasoline and electricity prices, and again compare these to the projections reported in EIA's

¹⁴⁹⁹ These inputs are all contained in the "trnldvx.xlsx" NEMS input file. The input file utilized for today's analysis is available in regulatory docket NHTSA-2018-0067, <https://www.regulations.gov/docket?D=NHTSA-2018-0067> (see Supporting Documents), as is the corresponding output file from which reference case fuel and electricity prices were obtained to be used as inputs to the CAFE model. The version of NEMS utilized for today's analysis is available at https://www.eia.gov/outlooks/aeo/info_nems_archive.php,

Figure I-II-1849 - NEMS-Based Gasoline Prices

Figure I-II-1950 - NEMS-Based Electricity Prices (Average to All Users)

The agencies used the resulting Reference case fuel prices as inputs to the rule's central analysis. The agencies also used the as-published (by EIA) "Low Oil Price" and "High Oil Price" case fuel prices as inputs to several of the cases included in the sensitivity analysis presented in the accompanying RIA.

For the projections of macroeconomic variables used in the analysis supporting this rule, the agencies elected to rely on different sources from those that informed their analysis of the proposed rule. Specifically, the agencies rely on projections of future growth in U.S. GDP reported in AEO2019 to support their central analyses of the final rule's impacts on new car and light truck sales and the retirement of used vehicles. These incorporate underlying projections

generated using the IHS Markit Global Insight long-term macroeconomic model, as modified via this model's interaction with NEMS' representation of global energy markets and their future outcomes. The alternative projections of future growth in GDP used in the agencies' accompanying sensitivity analyses are drawn from the AEO2019 High Economic Growth and Low Economic Growth cases. These reflect alternative future trends in U.S. labor force and productivity growth, and are also consistent with the energy market outcomes projected by NEMS under the resulting future performance of the U.S. economy.

For estimates of the number of U.S. households during future years, which influence the projections of new car and light truck sales used in the analysis, the agencies rely on projections of new household formation developed the Harvard University Joint Center for Housing Studies.¹⁵⁰¹ These are consistent with the most recent projections of future growth in the nation's population prepared by the U.S. Bureau of the Census.¹⁵⁰²

(2) *Approach to estimating sales response under different standards*

Prior to the NPRM, all previous CAFE and CO₂ rulemaking analyses used static fleet forecasts that were based on a combination of manufacturer compliance data, public data sources, and proprietary forecasts (or product plans submitted by manufacturers). When simulating compliance with regulatory alternatives, those analyses projected identical sales across the alternatives, for each manufacturer down to the make/model level—where the exact same number of each model variant was assumed to be sold in a given model year under both the least stringent alternative (typically the baseline) and the most stringent alternative considered (intended to represent “maximum technology” scenarios in some cases). To the extent that an alternative matched the assumptions made in the production of the proprietary forecast, using a static fleet based upon those assumptions may have been warranted. However, a sales forecast is unlikely to be representative of a broad set of regulatory alternatives with significant variation in the cost of new vehicles. A number of commenters on previous regulatory actions encouraged consideration of the potential impact of fuel efficiency standards on new vehicle prices and sales, and the changes to compliance strategies that those shifts could necessitate.¹⁵⁰³ In particular, the continued growth of the utility vehicle segment creates compliance challenges within some manufacturers' fleets as sales volumes shift from one region of the footprint curve to another, or as mass is added to increase the ride height of a vehicle on a sedan platform to create a crossover utility vehicle, which exists on the same place of the footprint curve as the sedan upon which it might be based.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

However, some NPRM commenters referenced the agencies' previous omission of this effect as justification to continue ignoring this issue in the current rulemaking. EDF commented,¹⁵⁰⁴ "use of a sales response model constitutes an unexplained reversal in the agency's position on the feasibility of doing so." To say that the agencies never used a model is a misrepresentation. Assuming that sales never change in any model year, even at the individual nameplate level, regardless of the stringency of fuel economy regulations or the technology costs required to comply with those regulations, is, itself, a model. It is a model that implicitly asserts that, while fuel economy regulation impacts vehicle prices, such regulations have no impact on the quantity or mix of new vehicle sold, regardless of stringency. This is an implicit argument that new vehicle demand is perfectly inelastic—and that no change in vehicle prices can impact the number of cars consumers will buy. Logically, however, there must exist a level of stringency that would have a negative impact on new sales. Picking an extreme example to prove the point, if the agencies set standards at an extraordinarily stringent level that forced all vehicles into battery electric propulsion systems next year, sales would obviously be impacted. The increase in new vehicle price or changes to other relevant attributes like range, refueling time, or operating cost would surely affect the decisions of some buyers. But, by arguing that the agencies should continue to model new vehicle sales as if they are entirely unaffected by standards, commenters are effectively asking the agencies to assume that the alternatives considered in this rule are insufficiently stringent to affect the market. By endorsing the approach from the 2012 final rule, which assumed no impact on the new vehicle market from standards as stringent as 7 percent increase, year-over-year, beginning in 2017, commenters are suggesting that even *those* standards would have no impact on new vehicle sales. Manufacturers have asserted in their comments that fuel economy regulations change both the cost of producing new vehicles and consumer demand for them. In the recent peer review of the NPRM release of the CAFE model, all reviewers encouraged the inclusion of a sales response to fuel economy regulations (albeit not necessarily the version of the response model that appeared in the NPRM).¹⁵⁰⁵ Based on earlier comments and our own analysis, the agencies were persuaded to include a sales response mechanism in the NPRM, and do so again in this final rule.

While several commenters (CARB, NCAT, CBD, Aluminum Association) discouraged the agencies from attempting to account for the effect of regulations on new vehicle sales, other commenters stated that the NPRM analysis was improved by explicitly considering this effect (RFF, Toyota, the Alliance of Automobile Manufacturers). CBD cited EPA's 2016 proposed determination, stating "[a] reasonable qualitative assessment is preferable to a quantitative estimate lacking sufficient basis, or (due to uncertainties like those here) having such an enormous range as to be without substantial value."¹⁵⁰⁶ However, RFF supported the inclusion of the effect (with caveats about the specific implementation, for which they suggested alternative approaches), stating "[i]ncorporating sales and scrappage effects represents a step in

the right direction for modeling the effects of the regulation.¹⁵⁰⁷ It is reasonable to conclude that regulations as transformative as fuel economy standards will impact the market for new vehicles, and excluding the effect (as CBD and others suggested) is equivalent to stating that it does not exist.

The NPRM version of the sales response relied on differences in the average price of new vehicles to produce sales differences between regulatory alternatives. Some commenters (ACEEE, IPI, CBD, UCS, Aluminum Association, and Alliance to Save Energy) argued that new vehicle prices do not increase with the addition of technology required to comply with fuel economy regulations. Some argued that manufacturers will choose not to “pass through” the full incremental cost of fuel saving technologies to consumers, instead absorbing those costs into their profit margin.¹⁵⁰⁸ The question of cost pass-through is one that academic and industry researchers have considered for decades—and two of our recent peer reviewers addressed this issue in their comments.

Dr. John D. Graham, one of the peer reviewers, argued that the assumption of complete cost pass-through is defensible, and more likely in the long-run than the short-run.¹⁵⁰⁹ The reviewer also suggested that changes to the CAFE (and subsequent CO₂) program that base a manufacturer’s standard on the mix of vehicle footprints in each fleet more equitably spreads the impact of the standards across the industry, and that industry shifts toward increasingly competitive market models (rather than the oligopolistic models that existed earlier in the last century) both act to increase the likelihood that manufacturers will pass regulatory costs through to consumers. In particular, this reviewer stated:¹⁵¹⁰

In a classic study, Gron and Swenson (2000) examined list prices of automobiles at the model level in the US from 1984 to 1994 coupled with data on production, vehicle characteristics, foreign versus domestic firm ownership, wages of employees, exchange rates, imported parts content, tariffs and other variables. Although their work rejects the hypothesis of 100% pass through of cost to consumer price, they find higher rates of pass through than previous studies, and much of the incomplete pass through occurs when cost increases impact only a few models or firms. Confirming earlier studies, they show that US auto manufacturers engage in more aggressive pass-through pricing than Asian and European manufacturers (greater than 100% in some specifications), possibly due to the eagerness of importers to enlarge market share in lieu of recovering regulatory costs, at

least in the short run (see Dinopolous and Kreinin, 1988;¹⁵¹¹; Froot, 1989¹⁵¹²). This study helps explain why pass-through pricing is a more viable hypothesis in the long run than in the short run.

The original design of the CAFE program is a contrasting case where pass-through pricing was difficult for some automakers. All auto makers, regardless of their product mix, were subject to the same fleet-wide average CAFE standard, such as 27.5 miles per gallon for cars in 1990. In practice, those standards impacted only three high-volume companies (General Motors, Ford and Chrysler) because the Big Three produced a higher proportion of large and performance-oriented vehicles than did Japanese companies. As a result, manufacturers such as Toyota and Honda consistently surpassed the federal fleet-wide standard for cars without any regulatory cost (i.e., partly due to their smaller product mix). In the 1975-2007 period, the Big Three were not able to pass on all of their compliance costs to consumers and thus experienced some declines in profitability due to CAFE (Kleit, 1990;¹⁵¹³ Kleit, 2004;¹⁵¹⁴ Jacobsen, 2013¹⁵¹⁵).

When the CAFE program was reformed for light trucks in 2008 (and for cars in 2011) on the basis of vehicle size (the so-called “footprint” adjustments to CAFE stringency), the, the technology costs of CAFE standards were spread more evenly among automakers, although the overall societal efficiency of the regulation diminished due to the removal of downsizing as a compliance option.¹⁵¹⁶ Given that the size-based fuel economy programs are not concentrating the costs of compliance on one or two automakers, it is reasonable to predict a fairly high degree of pass-through pricing for the 2021-2025 fuel economy standards. In related literature on manufacturer pricing responses to a national carbon tax, Bento and Jacobsen (2007)¹⁵¹⁷ and Bento (2013)¹⁵¹⁸ report high rates of pass-through pricing (on the order of 85%). Carbon taxes are more efficient than footprint-based CAFE standards, but both instruments are likely to impact a wide range of

companies in the auto sector and result in a high degree of pass-through pricing by impacted companies.

Also, it should be noted that the US automotive industry is much more competitive today than it was from 1970 to 2000. The market share of General Motors, once the dominant, majority producer in the U.S. market, has declined dramatically, and a variety of Japanese and Korean companies have captured substantial market share. Moreover, the rise of startups (e.g., Tesla and other electric vehicle start-ups) and ride-sharing services (e.g., Uber) are adding a new competitive dimension in the U.S. industry. As a result, some of the most recent auto regulatory studies have given more emphasis to analytic results based on competitive models than oligopolistic models (see, e.g., Davis and Knittel (2016)¹⁵¹⁹).

Another peer reviewer, Dr. James Saltee, suggested that costs would pass through to new vehicle buyers to different degrees, depending upon the stringency of the standards.¹⁵²⁰ The reviewer argued that more stringent standards, which result in larger increases to the cost of production, are likely to induce greater degrees of pass-through than less stringent standards, which automakers may, as some commenters have suggested, be able to absorb in the form of lost profit. If the degree of cost pass-through should vary by the stringency of the alternative, we are underestimating the difference in price between the most and least stringent alternatives—which would favor alternatives with higher stringency.

Other commenters argued that manufacturers are able to compensate fully for the costs of fuel economy standards by increasing the prices of luxury vehicles—which would increase the average new vehicle price, but leave large sections of the market unaffected by the increased cost of producing fleets that comply with the standards. While it seems likely that manufacturers employ pricing strategies that push regulatory costs (as well as increases in costs like pension obligations and health care costs for employees) into the prices of models and segments with less elastic demand, the extent to which any OEM is able to succeed at this is unknown by the agencies. At some point, however, price increases on even luxury models will merely price more and more purchasers out of the market, and make competition with other manufacturers and market segments that much more difficult. And the more that avoided price increases for lower ends of the vehicle market are subsidized by luxury vehicles, the more either prices for luxury models would need to be increased, or (if moderately increasing prices) more of those luxury models would need to be sold. It is worth noting that luxury vehicles tend to be more powerful and content-rich, and often have fuel economy levels below (or CO₂ levels above) their targets on the curves—so that selling more of them to compensate for lost profit elsewhere further erodes the compliance levels of the fleets in which they reside.

¹⁵¹⁹ Davis, Lucas, Knittel, Christopher R., Are Fuel Economy Standards Regressive? Working Paper 22925, National Bureau of Economic Research, Cambridge, MA (2016).

¹⁵²⁰ CAFE Model Peer Review, DOT HS 812 590, Revised (July 2019), pp. B54-B75, available at <https://www.regulations.gov/contentStreamer?documentId=NHTSA-2018-0067-0055&attachmentNumber=2&contentType=pdf>

While manufacturers could conceivably push some small cost increases into the prices of their vehicle segments that have less elastic demand to cover accordingly small increases in stringency, larger stringency increases would exhaust the ability of such segments to absorb additional costs. In addition, we do not attempt to adjust the mix of vehicle models based on their own price elasticity of demand; doing so would require a pricing model that takes the compliance cost for each manufacturer (which our model estimates dynamically) and apportions that cost to the prices of individual nameplates and trim levels. We have experimented with pricing models (when integrating vehicle choice models, pricing models are a necessity), but each manufacturer almost certainly has a unique pricing strategy that is unknown to the agencies, and involves both strategic decisions about competitive position within a segment and the volumes needed fully to amortize fixed costs associated with production. To the extent that the agencies assume all regulatory costs are passed through and affect the average regulatory cost of each vehicle instead of being priced in a fashion to minimize the impact on aggregate sales, the agencies note that—more stringent alternatives are provided an artificial analytical advantage because manufacturers are better positioned to incorporate smaller price adjustments into their current strategic pricing models. The agencies opted to take the conservative approach instead of speculating on manufacturer’s private business models.

Finally, some commenters have argued that, even if regulations *do* increase the cost of producing vehicles and those costs *are* passed on to new vehicle buyers, it does not matter because sales have increased in recent years under both rising standards and rising prices. EDF, CARB, Aluminum Association, SAFE, CBD, and CA et al. and Oakland et al., all make some version of this argument in their comments.¹⁵²¹ The commenters are confusing correlation with causation and failing to consider the counterfactual case. Higher prices of new vehicles certainly did not cause sales to increase since 2012. Sales increased over that period, in large part, as a result of economic expansion following the great recession.¹⁵²² The statistical model used in the NPRM attempted to isolate the effect of average price on new vehicle sales, independent of the overall health of the US economy which plays an obviously important role. That model showed a negative relationship between sales and price (albeit a modest one), and positive relationships with GDP and employment. Even under the most stringent alternative in the NPRM, sales increased over time. However, in other alternatives, where the same macroeconomic conditions prevailed but average new vehicle prices were lower, sales increased relative to the baseline. That is the counterfactual case that is relevant for regulatory analysis—it attempts to answer the question, “would sales have been even higher if average prices had been lower?”

As we discuss below, identifying the independent contribution of price to new vehicle sales is econometrically challenging. In the NPRM, we stated that the simultaneous nature of price and sales—where transaction prices are higher in periods of higher demand, because the market will bear them, and lower in periods of lower demand, because the market will not, for an

¹⁵²¹ See, e.g. EDF, Appendix B, NHTSA-2018-0067-12108, at 37; CARB, Detailed Comments, NHTSA-2018-0067-11873, at 198-204; Aluminum Association, Comments, NHTSA-2018-0067-11952, at 19-21; SAFE, Comments, NHTSA-2018-0067-11981 at 36; CBD *et al.*, Attachment 1, NHTSA-2018-0067-12123, at 20. ¹⁵²² [Table II-44](#)~~Table I-4~~ below shows a large and statistically significant effect of GDP on sales.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

otherwise identical vehicle—creates a form of reverse causality. As commenters suggested, in recent years sales have increased along with average transaction price increases—and transaction price increases will occur when regulation forces manufacturers to add content, and their corresponding costs, to the vehicles they sell. Thus, it is understandable that some commenters could interpret the recent increase in new vehicle sales following the recession as evidence that standards (and maybe prices) have no impact on new sales. However, that view confuses correlation for causation (or lack thereof, in this case).

In response to these comments, the agencies have modified their approach to modeling the sales impacts of regulatory alternatives. In order to isolate the impact of the standards, the agencies have broken the sales response module into two discrete components. The first captures the effects of broader economic forces such as GDP growth. The second measures how changes in vehicle prices influence sales. As elaborated in more detail in the following passages, the agencies considered alternative approaches and specific changes suggested by commenters, but concluded that the comments either lacked enough information to implement a change, failed to remedy identified alleged weaknesses of the NPRM model, or created new limitations for which there were no practical solutions. Furthermore, the two-pronged approach addresses many of the concerns raised by commenters better than any specific modeling alteration. First, the structural changes to the model address many of the econometric concerns raised by commenters. Second, by modeling sales in the first step as a function of macroeconomic conditions, and then applying an independent own-price elasticity to estimate the change in sales across alternatives, we are able to more clearly distinguish between demand-side and supply-side impacts on prices, the issue that appears to have tripped up some of the commenters.

Comments on the econometric model used in the NPRM

Any model of sales response must satisfy two requirements: it must be appropriate for use in the CAFE model, and it must be econometrically reasonable. The first of these requirements implies that forecasts of any variable used in the estimation of the econometric model must also be available as a forecast throughout the duration of the years covered by the simulations (this analysis explicitly simulates compliance through MY 2050). Some values the model calculates endogenously, making them available in future years for sales estimation, but others must be known in advance of the simulation. As the CAFE model simulates compliance, it accumulates technology costs across the industry and over time. By starting with the last known average transaction price (associated with MY 2016, in this analysis) and adding accumulated regulatory costs to that value, the model is able to represent an estimated average selling price in each future model year, assuming that manufacturers are able to pass their compliance costs on to buyers of new vehicles. Other variables used in the estimation can be entered into the model as inputs prior to the start of the compliance simulation.

The NPRM analysis was based on an econometric model that attempted to estimate the price elasticity of aggregate demand for new light-duty vehicles based on exogenous factors, intended to represent (1) macroeconomic forces that influence demand for new vehicles, and (2) average new vehicle price, intended to represent the impact of regulation. A number of

commenters voiced opposition to the approach. Some disagreed with the theoretical framing of the issue—arguing that the model of sales response should have acknowledged the relevance of other vehicle attributes, included consumer valuation of fuel savings for new vehicles, based the response on something other than price, and considered the effect at a lower level of aggregation, rather than average price across the industry.

In the NPRM, the agencies relied upon an autoregressive distributed lag (ARDL) statistical model to estimate the impact of price differences between regulatory alternatives and to produce a time series of total new vehicle sales in each year of the analysis. The statistical model estimated new vehicle sales per year based on two lagged variables of new sales (new sales in the previous period, and the period before that), GDP and lagged GDP, and labor force participation and lagged labor force participation. The model used quarterly data and seasonally adjusted annual rates to increase the number of observations over the sample period for which reliable sales data existed (1978-2015). The ARDL model used in the NPRM was chosen to address sales impacts at a high level of aggregation, namely the total new vehicle market (across all vehicle brands and body styles), and to resolve the econometric issues associated with the time series data related to total new vehicle sales.

Stock et al. commented at length on the econometric specification of the NPRM sales response model, identifying limitations and suggesting alternative approaches.¹⁵²³ In particular, they argued that the length of the response to price shocks should dissipate faster than the NPRM model allows—an artifact of using quarterly data and seasonally adjusted annual rates to estimate the effect and implementing it on an annual basis in the CAFE model. We agree that this was a flaw in the implementation of the NPRM model. While this approach produced the correct units (i.e., annual sales) the response to changes in price should have dissipated at a quarterly rate, rather than an annual rate. As a result, a single price shock, which appears in one year and disappears the next, was projected to have a longer impact on sales in future years than was appropriate given the specification. The sales response in the final rule corrects for this objective error and takes a more conservative approach to price shocks.

Stock et al. commented that “it is important to estimate the dynamic effect on sales of a price increase, that is, the causal effect on current and future demand of a price increase” because “it allows the response to an intervention—here, a one-time price increase or sequence of such increases—to evolve over time.”¹⁵²⁴ The comment suggests that we should include future responses in sales to a one-time price increase that exists for a single period and then disappears. In our analytical framework, this implies that a price difference between any alternative and the baseline that causes a difference in sales in that year should also produce a difference in sales in the following year (and possibly subsequent years), though of smaller magnitude, even if the price difference only exists for a single period. The Stock et al. comment illustrates a quickly diminishing response to a single price shock. The final rule assumes (more conservatively) that each price shock lasts only for a single year, and produces no future “ripple” effects in the new

¹⁵²³ [EPA–HQ–OAR–2018–0283 and NHTSA–2018–0067]

¹⁵²⁴ Ibid.

vehicle market in subsequent years. Furthermore, the regulatory alternatives considered in this analysis do not produce single period price shocks (in the form of price differences between alternatives), but rather persistent price differences between alternatives that result from continued differences in stringency. The persistent nature of the price differences resulting from fuel economy and CO₂ regulations further reduce the importance of capturing these multi-period effects caused by single-period price shocks.

Stock et al. also objected to the use of an ARDL model to estimate the impact of price on new vehicle sales. In order for the estimation of causality to be valid in a time series model, the current price movements must be uncorrelated with unobserved demand shocks in the past, present, and future; so-called strict exogeneity. The commenters argue that the NPRM fails this test because actions taken in the market (by both buyers and sellers) can influence the response to price changes in the next period. They suggest the use of a vector autoregression (VAR) model to address the relationship between past demand disturbances and current prices to address the temporal exogeneity issues they identify. However, an important caveat is that this approach still does not resolve the largest econometric challenge—that of contemporaneous endogeneity between price and sales (in the same period). To address that challenge, one needs to employ instrumental variable methods.

We attempted several modifications to the statistical model developed for the NPRM based on the Stock et al. comment. We reviewed the initial approach and attempted several specifications that would explicitly address the temporal endogeneity bias identified in the comment. In particular, we addressed data limitations that were raised by Stock et al. (and also by EDF), who encouraged us to reconsider the quarterly specification and to use quality-adjusted price data for new vehicles in order to ensure a more consistent definition of the average vehicle over the time series, as the “average vehicle” has consistently improved in a myriad of ways over successive model years. The quarterly price series was statistically interpolated in the NPRM to increase the number of observations,¹⁵²⁵ but represented a less-than-ideal solution. The interpolating process may have impacted the underlying quarterly data generating process, resulting in unreliable, or potentially biased, regression results. This issue was remedied by sourcing both vehicle sales and price data from IHS Markit, which provides these data at the same base frequency (quarterly) and obviates the need for any interpolation. In addition, the macroeconomic data used in the model specification were also sourced from IHS, which provides consistency between historical and forecast data (i.e., forecasts of sales, price, personal income, etc., were all based on a consistent set of input assumptions and modeling framework during testing).

Historical quarterly series for new light vehicle average price and total sales are presented in [Figure II-20](#)~~Figure VI-45~~ below. Due to the lack of data availability for business investment in light vehicles, the historical series for average vehicle price begins in 1987. Average prices

¹⁵²⁵ Interpolation is the practice of adding unobserved data points based on observed trends to provide more observations to a limited data set.

were transformed into quality adjusted real terms using the CPI for new motor vehicles, and both series were seasonally adjusted.¹⁵²⁶ Quality adjusted prices have risen overtime, while total sales have remained relatively flat in recent years with the major exception being the significant economic downturn of 2008-2009. The difference in these trends suggests that the number of vehicles purchased per household does not necessarily change, or grow, over time, as income grows, but rather households adjust the “amount” of new vehicle they are willing to purchase (i.e., switching from sedan to an SUV).¹⁵²⁷ Moreover, while disposable income has steadily increased during this period, sales have not seen the same type of upward trend, and instead only returned to its pre-recession average of around 17 million annual sales.

Figure II-2054 - New Light Duty Vehicle Average Price and Total Sales

Even as real disposable income has risen since 2000, and outside of the great recession, new vehicle sales have remained relatively steady. This, in turn, suggests there are other economic, or behavioral, factors beyond disposable income influencing the decision to purchase a new vehicle. Given the significant cost to purchase a new vehicle, and the long multiyear timeframe over which they are typically financed, households’ forward-looking view on the health of the economy likely plays a role in their willingness to purchase a new vehicle. Put

¹⁵²⁶ Seasonal adjustment was made using X.12 in EViews.

¹⁵²⁷ Aggregate light duty vehicle sales data does not allow for observing the distribution of vehicles being sold, which will have an effect on the average price.

differently, households may delay their purchasing decisions if their view outlook on the economy sours, regardless of income level. These observations are consistent with the framework of the NPRM model, and [Figure II-21](#)~~Figure VI-46~~ presents the consumer sentiment index and total new sales, with both series exhibiting similar trends over this period. Some commenters advocated that consumer sentiment (also known as consumer confidence) should be included in the sales forecast. For example, the Aluminum Association indicated that prior sales models have shown consumer behavior to be “highly sensitive to macroeconomic conditions, consumer confidence and employment levels.” While consumer sentiment was not included in the NPRM model, it was included in specifications that we tested and considered and is a component of the forecasting model used in the final rule.¹⁵²⁸

Figure II-~~21~~⁵² - Consumer Sentiment and Total Sales

All macroeconomic data were sourced from IHS including real disposable income, number of US households, and the University of Michigan’s consumer sentiment index. The summary statistics for all series are presented below in [Table II-44](#)~~Table VI-124~~.

¹⁵²⁸Commenters mentioned consumer confidence as a predictor of consumer behavior. For instance, the Aluminum Association indicated that prior sales models have shown consumer behavior to be “highly sensitive to macroeconomic conditions, consumer confidence and employment levels.” Comments, NHTSA-2018-0067-11952, at 14.

Table II-4417 - Summary Statistics

Variable	Obs.	Mean	Std.	Min	Max
Quality Adjusted Real Avg. LDV Price (Thousands, 2012\$)	127	24.13	5.29	15.74	32.89
Total LDV Sales (SA Annual Rate, Millions)	127	15.23	1.93	9.38	18.53
Real Disposable Income (Billions, 2012\$)	127	9,979.94	2,432.22	6,113.99	14,358.03
Number of Households (Millions)	127	110.36	9.19	93.53	126.35
Consumer Sentiment Index	127	87.66	11.68	57.67	110.13

Each series was transformed into natural logarithms and tested for stationarity using the modified Dicky-Fuller test.¹⁵²⁹ Results presented in Table II-45Table VI-125 indicate each variable containing contained a unit-root, while being differenced stationary (i.e. integrated of order one).

Table II-4518 - Modified Dickey-Fuller Test (1 lag)

	DF-GLS Test Stat.	1% Critical Value	5% Critical Value	10% Critical Value

Two separate variables lists were then tested for the existence of one or more cointegrating relationships, with results from the Johansen test presented in [Table II-46](#)¹⁵³⁰. In each set of variables, both total LDV sales and disposable income were converted to household units as a means to control for the growth in US households and the possible decision making process of buying/consuming a new unit of LDV. The results show that 4 out of the 5 lag length selections for both variable sets conclude there being one cointegrating relationship (rank I(1)) among them.

Table II-46 - Johansen Test for Cointegration

Series	Lags	Max Rank	Trace Stat.	5% Critical Value
NL LDV Sales per HH, NL PDI per HH, NL Avg. LDV Price	2	1	9.9139	15.41
	3	0	28.6582	29.68
	4	1	8.8639	15.41
	5	1	7.9938	15.41
	6	1	12.6687	15.41
NL LDV Sales per HH, NL PDI per HH, NL Avg. LDV Price, NL JCSM	2	2	10.2220	15.41
	3	1	25.8108	29.68
	4	1	29.2521	29.68
	5	1	21.7739	29.68
	6	1	27.1268	29.68
Note: NHH, PDI, and JCSM refer to households, real personal disposable income, and consumer sentiment, respectively. All tests include an unrestricted constant. Alternative tests were conducted to include restricted trend or constant terms, but are not presented here for brevity as our preferred specification only includes an unrestricted constant term in the model.				

Taken together, these tests confirm the need to address the time series properties of each variable in any modeling framework. This will become especially important when discussing the correct modeling approach, as The pre-modeling tests provide evidence against running a simple OLS regression or VAR in first differences, because doing so would have the potential outcome of excluding important long-run information.

¹⁵³⁰ The number of lag lengths were also tested formally, with general consensus between 2 and 6 lags as being optimal. Test results are available upon request, however, the final lag length selection was determined on the full set of VAR and VECM output that includes satisfying time series conditions such as no presence of autocorrelation and plausible interpretability of the estimated output.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Furthermore, the endogeneity between vehicle sales and price is another element that needs to be considered for model specification. The IHS historical series for average price of a new light duty vehicle is defined as a function of business and private residential spending on light vehicles divided by total new light vehicle sales; from this identity, the average price represents the nominal price per new unit of light duty vehicle sold. This definition supports the existence of an endogenous relationship between vehicle price and sales that needs to be accounted for when developing an econometric estimation of the influence of new vehicle price on sales. This is consistent with economic theory, whereby vehicle sales and price are simultaneously determined in the market, and therefore should be included together when specifying a forecasting equation.¹⁵³¹ This restriction holds even if nominal vehicle price is transformed into a quality adjusted real dollar series, as some commenters (EDF, Stock et al) proposed.¹⁵³²

Models

Faced with the simultaneity problem associated with price and sales, several specifications were reviewed to determine the best method for addressing this issue. An Instrumental Variable (IV) method was deemed the most direct approach, with the advantage of preserving the initial model's autoregressive distributed lag structure. In order to obtain consistent estimates of the price elasticity of demand, a suitable instrument that is correlated with average LDV price but uncorrelated with the error term is needed in the first stage. A suitable instrument must also make economic sense and have a plausible causal relationship. In theory, instruments that satisfy all three conditions (exogeneity, causality, and non-weak correlation) should exist. In practice, however, it is often prohibitively difficult to find a viable instrument. Both Stock et al. and CARB suggested instrumenting to resolve the endogeneity issue in the NPRM model, but neither suggested specific candidates for instrumental variables.

For the purposes of modeling vehicle sales, candidate IVs would reflect the price of inputs to production that are broad enough, so that the underlying behavior of the variable is not deterministic of LDV sales. Examples of candidate variables include producer price indices (PPIs) of auto or other related manufacturing, cost of capital required for production, labor market data, energy costs, technology changes, and exogenous shocks to price, production, labor, or policy changes.

The lack of data availability and quality concerns reduced the primary list of candidate IVs to reliable PPIs such as for manufacturing and automobile primary products. Even the most "promising" candidate IVs, however, proved to be poor instruments, with counterintuitive signs,

¹⁵³¹ Endogeneity results in correlation between an independent variable in a regression and the error term leading to biased coefficient estimates.

¹⁵³² For reference on how the BLS measures quality adjustments in vehicles:
<https://www.bls.gov/cpi/factsheets/new-vehicles.htm>.

lack of statistical significance, and poor overall first stage F-statistics (even by relatively lenient weak instrument test standards).

The lack of reasonable results from the IV approach led to testing vector autoregressive (VAR) and vector error correction (VECM) models. Relaxing the strict exogeneity assumption needed under an ARDL framework is the main advantage of modeling price, sales, and macroeconomic variables as a system of equations where the feedback from previous period shocks affect both price and sales.¹⁵³³ In addition, a VAR or VECM can also adequately handle the time series and nonstationary properties discussed above. For both the VAR and VECM, a parsimonious specification was preferred with either a three or four variable system using the variables discussed above.

We first estimated a simple VAR using a Wold causal ordering of real disposable income per household, average price of new LDV, and new total sales of LDVs per household.¹⁵³⁴ The alternative specification included the consumer sentiment variable in the ordering the consumer sentiment variable after income and before price. This ordering assumes that households' disposable income (and consumer sentiment) do not respond to shocks to auto prices and sales within the same quarter. It also assumes that prices are contemporaneously exogenous of sales (demand), since the MSRPs are set in advance. Lastly, sales are able to respond to unexpected changes in price in the same quarter. The alternative ordering of placing sales before average price was deemed unrealistic as it would presume sales responding independently to an unexpected change in prices.

In the first specification, all variables were transformed to first differences to ensure stationarity, while ignoring any possible long-run information (for the moment). A combination of post-estimation tests for autocorrelation and stability conditions were considered along with impulse response functions to gauge the model performance. The preferred model was estimated with five lags, and the impulse response functions (IRF) of a 1 percent shock to price on sales for the two specifications are presented in [Figure VI-53](#)~~Figure I-3~~.

¹⁵³³ Strict exogeneity requires there to be past, contemporaneous, and future exogeneity between the variables of interest.

¹⁵³⁴ The Wold causal ordering creates a lower triangular matrix for our shocks, so by construction these shocks are orthogonal to each other to allow for causal inference. This recursive or Wold ordering technique should be predetermined and based on economic theory as the causal interpretation of the impulse responses are dependent on the correct/plausible ordering of variables.

Figure II-2253 - Impulse Response Functions of Price on Sales from First Difference VARs

Both figures show a similar trend of the response in sales oscillating from negative to positive before ultimately returning to zero 12 quarters out. The three variable VAR sees a positive response in the first few periods, while the four variable VAR manages to dip below zero briefly after 4 periods out. This behavior, which by definition is short-run due to the differencing of the variables, could be representing auto dealerships' attempts to pull sales back to its equilibrium level after the price shock pushes sales negative, implying some level of over compensation during this process. Nonetheless, despite the model showing there is some evidence of an immediate and negative price elasticity, the overly simplified VAR model is missing key long run information (as identified in the cointegration tests), creating some reservations about the results. It is also worth noting that the lagged positive response in sales from an unexpected price shock is persistent regardless of the lag length selection, and in many cases even more pronounced.

A number of preliminary conclusions can be drawn from the IRF results shown in [Figure VI-53](#). First, at least at this level of aggregation, any short-run and immediate effect of a price increase on total LDV sales is relatively small in nature. This does not suggest, however, that the price elasticity of demand is zero. Instead, what may be the case is that when faced with an unexpected change in price, consumers will choose to purchase a less expensive car with fewer features as opposed to no car at all. In other words, the level of aggregation being used, total car sales, removes important variation between the type of vehicle being sold and consumer purchasing decisions from the data; what is left is a clouded version of the true relationship between price and sales. Second, this type of VAR ignores and throws out any long run information that may exist, which would create omitted variable bias if such a cointegrated relationship exists.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Based on the conclusions from the Johansen cointegration test, the next step involved estimating the system as a VECM. As with the VAR models, the VECM employs either a three or four variable system with five lag lengths and an unconstrained constant in the model (no trend in either the first differenced or cointegrating equations). In each model, the cointegrating vector is normalized around sales (i.e. the sales' coefficient is set to 1), and the model results indicate strong evidence of a cointegrating relationship between the variables.

Aside from general agreement on a cointegrating relationship, the VECM performance was weak in nearly every specification attempted, with implausible magnitudes for the long-run coefficient estimates and insignificant short-run dynamics. Moreover, the adjustment coefficient for the sales equation is particularly weak and insignificant.¹⁵³⁵ The limitations of the VECM could be rooted in the system being normalized around sales, which lacks significant variation, correlation, or possibly true causation with the other variables.

As with the VAR analysis, a similar focus is placed on the IRFs presented in [Figure VI-54](#)~~Figure I-4~~. Here a one percent shock in price on LDV sales shows a similar response between the two specifications, with an increase during the first several periods before returning to a negative and permanent long-run effect. This response is erroneous in two ways: first, the sharp positive response during the first 8 to 10 quarters defies economic logic as an increase in the price of a normal good should not induce an increase in sales. Second, the permanent and negative effect is equally as confounding because it rules out the ability for dealerships or auto manufacturers to adjust prices or supply.¹⁵³⁶

The updated econometric models of light duty vehicle sales (described above) thus did not provide clear, significant or robust insight into the magnitude of the price elasticity of demand. While the VAR model specification points to an immediate short-run negative price elasticity of demand (i.e., sales fall in the face of an immediate price shock), this relationship is relatively small. In addition, the fact that this specification excludes the identified cointegration between the variables suggests that it is not robust or unbiased. In short, the VECM and IV approaches were unable to provide reasonable and meaningful results.

These results strongly suggest that the relationship between sales and price is not adequately estimated with the macro-level data used in this analysis. Recent peer reviewers of the CAFE model had similar concerns. In particular, these data are insufficient to explain the individual consumer (micro-) level decision making process of purchasing a new LDV. Aggregating the sales response to the national level reduces the useful variation in the decision

¹⁵³⁵ The lack of a statistically significant adjustment variable could be an indication of weak exogeneity. In this case that would not be plausible given the clear endogeneity between price and sales, and is more likely an indication of poor data and the absence of reliable modelling approaches.

¹⁵³⁶ Note that error bounds cannot be generated for VECM IRFs using most statistical packages, so determining statistical significance is difficult. Given the change from positive to negative and the low magnitude of the response, it is quite possible that this effect is indistinguishable from zero.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

making process to levels unsuitable for estimation. Commenters generally agreed with this conclusion.

Even assuming a theoretically and econometrically correct model was possible, this relationship is impossible to evaluate at the current data aggregation level. Future research may focus on constructing an aggregate price elasticity of demand from consumer level data utilizing discrete choice modeling or something similar. However, constructing such models and integrating them into the simulations of the final rule are beyond the scope of this analysis.

Figure II-2354 - Impulse Response Functions of Price on Sales from VECMs

Many commenters suggested that the NPRM model was unable to find a statistically significant influence of fuel economy on sales because the model was too highly aggregated, as we found with the econometric experimentation to estimate a price response. EDF, CARB, and CA et al. and Oakland et al. expressed concern that using industry averages eliminated the variation needed to detect consumer valuation of fuel economy in new vehicle purchases. We noted a similar concern in the NPRM, citing the level of aggregation as the most likely reason that the average fuel economy of a new vehicle was not a statistically significant explanatory variable in the ARDL model. The approach for the final rule includes an average value of improved fuel economy in the sales response, as commenters suggested it should.

(a) *How do Car and Light Truck Buyers Value Improved Fuel Economy?*

Many commenters (CARB, CA et al and Oakland et al., NRDC, EDF, CBD, North Carolina Department of Environmental Quality, IPI, EPA Science Advisory Board, Stock et al.) stated that the agencies should explicitly consider fuel savings, and the value that consumers ascribe to it, in addition to changes in price when estimating the response of new vehicle sales to

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

different regulatory alternatives. NRDC stated, “The decision between new vehicle purchase alternatives must consider both differential costs and differential benefits.¹⁵³⁷ The CAFE model sales algorithm considers only differential costs and is, therefore, flawed.” The agencies agree that the degree to which new vehicle buyers value improvements in fuel economy is an important consideration when estimating the response of new vehicle sales to potential standards. The effect of vehicle prices on sales is difficult to detect at the aggregate level because price movements are correlated with the current strength of the economy, which can appear as a positive price elasticity when modeling sales, and there are various technical econometric difficulties in identifying the effect of price on sales (simultaneity, cointegration, etc., addressed above). The sales response model in the final rule accounts for fuel savings realized by buyers of new vehicles.

Some commenters and EPA’s Science Advisory Board noted that the sales response equation omitted any value of fuel savings to new vehicle buyers, while other elements of the analysis—notably the technology application algorithm—assumed that buyers would demand fuel economy technologies that “pay back” within the first 2.5 years of ownership (as a result of avoided fuel costs), and manufacturers would supply fuel economy at those levels even in the absence of standards. This observation was made in comments by CARB, CBD, and IPI—the last of which stated that 2.5 year payback assumption “clashes directly with the contradictory assumption that the agencies rely on in the model’s sales module, where they implicitly assume that customers entirely disregard fuel efficiency in their purchasing decisions.”¹⁵³⁸ We agree that this represented an internal inconsistency. The sales model used to analyze the final rule includes the estimated value of fuel savings to vehicle buyers, and is consistent with other assumptions throughout the analysis about the “pay back” period.

How potential buyers value improvements in the fuel economy of new cars and light trucks is an important issue in assessing the benefits and costs of government regulation. If buyers fully value the savings in fuel costs that result from higher fuel economy, manufacturers will presumably supply any improvements that buyers demand, and vehicle prices will fully reflect future fuel cost savings consumers would realize from owning— and potentially re-selling— more fuel-efficient models. If consumers internalize fuel savings this case, more stringent fuel economy standards will impose net costs on vehicle owners and can only result in social benefits through correcting externalities, because consumers would already fully incorporate private savings into their purchase decisions, — as discussed further below. If instead consumers systematically undervalue some market failure such as an information asymmetry leads to an underinvestment in fuel-saving technology, the cost savings generated by improvements in fuel economy when choosing among competing models, more stringent fuel economy standards will also lead manufacturers to adopt improvements in fuel economy that buyers might not choose despite the cost savings they offer and improve consumer welfare.

¹⁵³⁷ NRDC, Attachment 3, NHTSA-2018-0067-11723, at 4.

¹⁵³⁸ IPI, Appendix, NHTSA-2018-0067-12213, at 16.

The potential for car buyers voluntarily to forego improvements in fuel economy that offer savings exceeding their initial costs is one example of what is often termed the “energy-efficiency gap.” This appearance of such a gap, between the level of energy efficiency that would minimize consumers’ overall expenses and what they actually purchase, is typically based on engineering calculations that compare the initial cost for providing higher energy efficiency to the discounted present value of the resulting savings in future energy costs.

There has long been an active debate about why such a gap might arise and whether it actually exists. Economic theory predicts that individuals will purchase more energy-efficient products only if the savings in future energy costs they offer promise to offset their higher initial costs. However, the additional up-front cost of a more energy-efficient product includes more than just the cost of the technology necessary to improve its efficiency; because consumers have a scarcity of resources, it also includes the opportunity cost of any other desirable features that consumers give up when they choose the more efficient alternative. In the context of vehicles, whether the expected fuel savings outweigh the opportunity cost of purchasing a model offering higher fuel economy will depend, among other things, on how much its buyer expects to drive, his or her expectations about future fuel prices, the discount rate he or she uses to value future expenses, the expected effect on resale value, and whether more efficient models offer equivalent attributes such as performance, carrying capacity, reliability, quality, or other characteristics.

Published literature has offered little consensus about consumers’ willingness-to-pay for greater fuel economy, and whether it implies over-, under- or full-valuation of the expected discounted fuel savings from purchasing a model with higher fuel economy. Most studies have relied on car buyers’ purchasing behavior to estimate their willingness-to-pay for future fuel savings; a typical approach has been to use “discrete choice” models that relate individual buyers’ choices among competing vehicles to their purchase prices, fuel economy, and other attributes (such as performance, carrying capacity, and reliability), and to infer buyers’ valuation of higher fuel economy from the relative importance of purchase prices and fuel economy.¹⁵³⁹ Empirical estimates using this approach span a wide range, extending from substantial undervaluation of fuel savings to significant overvaluation, thus making it difficult to draw solid conclusions about the influence of fuel economy on vehicle buyers’ choices.¹⁵⁴⁰ Because a vehicle’s price is often correlated with its other attributes (both measured and unobserved), analysts have often used instrumental variables or other approaches to address endogeneity and other resulting concerns.¹⁵⁴¹

Despite these efforts, more recent research has criticized these cross-sectional studies; some have questioned the effectiveness of the instruments they use,¹⁵⁴² while others have

¹⁵³⁹ In a typical vehicle choice model, the ratio of estimated coefficients on fuel economy — or more commonly, fuel cost per mile driven — and purchase price is used to infer the dollar value buyers attach to slightly higher fuel economy.

¹⁵⁴⁰ See Helfand & Wolverton (2011) and Green (2010) for detailed reviews of these cross-sectional studies.

¹⁵⁴¹ See, e.g., Barry, et al. (1995).

¹⁵⁴² See Allcott & Greenstone (2012).

observed that coefficients estimated using non-linear statistical methods can be sensitive to the optimization algorithm and starting values.¹⁵⁴³ Collinearity (i.e., high correlations) among vehicle attributes—most notably among fuel economy, performance or power, and vehicle size—and between vehicles’ measured and unobserved features also raises questions about the reliability and interpretation of coefficients that may conflate the value of fuel economy with other attributes (Sallee, et al., 2016; Busse, et al., 2013; Allcott & Wozny, 2014; Allcott & Greenstone, 2012; Helfand & Wolverton, 2011).

In an effort to overcome shortcomings of past analyses, three studies published fairly recently rely on panel data from sales of individual vehicle models to improve their reliability in identifying the association between vehicles’ prices and their fuel economy (Sallee, et al. 2016; Allcott & Wozny, 2014; Busse, et al., 2013). Although they differ in certain details, each of these analyses relates changes over time in individual models’ selling prices to fluctuations in fuel prices, differences in their fuel economy, and increases in their age and accumulated use, which affects their expected remaining life, and thus their market value. Because a vehicle’s future fuel costs are a function of both its fuel economy and expected gasoline prices, changes in fuel prices have different effects on the market values of vehicles with different fuel economy; comparing these effects over time and among vehicle models reveals the fraction of changes in fuel costs that is reflected in changes in their selling prices (Allcott & Wozny, 2014). Using very large samples of sales enables these studies to define vehicle models at an extremely disaggregated level, which enables their authors to isolate differences in their fuel economy from the many other attributes, including those that are difficult to observe or measure, that affect their sale prices.¹⁵⁴⁴

These studies point to a somewhat narrower range of estimates than suggested by previous cross-sectional studies; more importantly, they consistently suggest that buyers value a large proportion —and perhaps even all —of the future savings that models with higher fuel economy offer.¹⁵⁴⁵ Because they rely on estimates of fuel costs over vehicles’ expected remaining lifetimes, these studies’ estimates of how buyers value fuel economy are sensitive to

¹⁵⁴³ See Knittel & Metaxoglou (2014).

¹⁵⁴⁴ These studies rely on individual vehicle transaction data from dealer sales and wholesale auctions, which includes actual sale prices and allows their authors to define vehicle models at a highly disaggregated level. For instance, Allcott & Wozny (2014) differentiate vehicles by manufacturer, model or nameplate, trim level, body type, fuel economy, engine displacement, number of cylinders, and “generation” (a group of successive model years during which a model’s design remains largely unchanged). All three studies include transactions only through mid-2008 to limit the effect of the recession on vehicle prices. To ensure that the vehicle choice set consists of true substitutes, Allcott & Wozny (2014) define the choice set as all gasoline-fueled light-duty cars, trucks, SUVs, and minivans that are less than 25 years old (i.e., they exclude vehicles where the substitution elasticity is expected to be small). Sallee et al. (2016) exclude diesels, hybrids, and used vehicles with less than 10,000 or more than 100,000 miles.

¹⁵⁴⁵ Killian & Sims (2006) and Sawhill (2008) rely on similar longitudinal approaches to examine consumer valuation of fuel economy except that they use average values or list prices instead of actual transaction prices. Since these studies remain unpublished, their empirical results are subject to change, and they are excluded from this discussion.

the strategies they use to isolate differences among individual models' fuel economy, as well as to their assumptions about buyers' discount rates and gasoline price expectations, among others. Since Anderson et al. (2013) found evidence that consumers expect future gasoline prices to resemble current prices, we use this assumption to compare the findings of the three studies and examine how their findings vary with the discount rates buyers apply to future fuel savings.¹⁵⁴⁶

As ~~Table II-44~~~~Table VI-124~~ Table I indicates, Allcott & Wozny (2014) found that consumers incorporate 55% percent of future fuel costs into vehicle purchase decisions at a six percent discount rate, when their expectations for future gasoline prices are assumed to reflect prevailing prices at the time of their purchases. With the same expectation about future fuel prices, the authors report that consumers would fully value fuel costs only if they apply discount rates of 24 percent% or higher. However, these authors' estimates are closer to full valuation when using gasoline price forecasts that mirror oil futures markets, because the petroleum market expected prices to fall during this period (this outlook reduces the discounted value of a vehicle's expected remaining lifetime fuel costs). With this expectation, Allcott & Wozny (2014) find that buyers value 76% percent of future cost savings (discounted at six percent) from choosing a model that offers higher fuel economy, and that a discount rate of 15 percent% would imply that they fully value future cost savings. Sallee et al. (2016) begin with the perspective that buyers fully internalize future fuel costs into vehicles' purchase prices and cannot reliably reject that hypothesis; their base specification suggests that changes in vehicle prices incorporate slightly more than 100 percent% of changes in future fuel costs. For discount rates of five to six percent, the Busse et al. (2013) results imply that vehicle prices reflect 60 to 100 percent% of future fuel costs. As ~~Table II-47~~~~Table VI-127~~ suggests, higher private discount rates move all of the estimates closer to full valuation or to over-valuation, while lower discount rates imply less complete valuation in all three studies.

Table II-~~47~~~~20~~ - Percent of Future Fuels Costs Internalized in Used Vehicle Purchase Price using Current Gasoline Prices to Reflect Expectations (for Base Case Assumptions)

¹⁵⁴⁶ Each of the studies makes slightly different assumptions about appropriate discount rates. Sallee et al. (2016) use five percent in their base specification, while Allcott & Wozny (2014) rely on six percent. As some authors note, a five to six percent discount rate is consistent with current interest rates on car loans, but they also acknowledge that borrowing rates could be higher in some cases, which could be used to justify higher discount rates. Rather than assuming a specific discount rate, Busse et al. (2013) directly estimate implicit discount rates at which future fuel costs would be fully internalized; they find discount rates of six to 21 percent% for used cars and one to 13 percent% for new cars at assumed demand elasticities ranging from -2 to -3. Their estimates can be translated into the percent of fuel costs internalized by consumers, assuming a particular discount rate. To make these results more directly comparable to the other two studies, we assume a range of discount rates and uses the authors' spreadsheet tool to translate their results into the percent of fuel costs internalized into the purchase price at each rate. Because Busse et al. (2013) estimate the effects of future fuel costs on vehicle prices separately by fuel economy quartile, these results depend on which quartiles of the fuel economy distribution are compared; our summary shows results using the full range of quartile comparisons.

Authors (Pub. Date)	Discount rate			
	3%	5%	6%	10%
Busse, et al. (2013)*	54%-87%	60%-96%	62%-100%	73%-117%
Allcott & Wozny (2014)	48%		55%	65%
Sallee, et al. (2016)		101%		142%

*Note: The ranges in the Busse et al. estimates depend on which quartiles of the fuel economy distribution are compared. With no prior on which quartile comparison to use, this analysis presents the full quartile comparison range.

The studies also explore the sensitivity of the results to other parameters that could influence their results. Busse et al. (2013) and Allcott & Wozny (2014) find that relying on data that suggest lower annual vehicle use or survival probabilities, which imply that vehicles will not last as long, moves their estimates closer to full valuation, an unsurprising result because both reduce the changes in expected future fuel costs caused by fuel price fluctuations. Allcott & Wozny's (2014) base results rely on an instrumental variables estimator that groups miles-per-gallon (MPG) into two quantiles to mitigate potential attenuation bias due to measurement error in fuel economy, but they find that greater disaggregation of the MPG groups implies greater undervaluation (for example, it reduces the 55 percent% estimated reported in [Table II-44Table VI-124](#) Table 1 to 49 percent%). Busse et al. (2013) allow gasoline prices to vary across local markets in their main specification; using national average gasoline prices, an approach more directly comparable to the other studies, results in estimates that are closer to or above full valuation. Sallee et al. (2016) find modest undervaluation by vehicle fleet operators or manufacturers making large-scale purchases, compared to retail dealer sales (i.e., 70 to 86 percent%).

Since they rely predominantly on changes in vehicles' prices between repeat sales, most of the valuation estimates reported in these studies apply most directly to buyers of used vehicles. Only Busse et al. (2013) examine new vehicle sales; they find that consumers value between 75 to 133 percent% of future fuel costs for new vehicles, a higher range than they estimate for used vehicles. Allcott & Wozny (2014) examine how their estimates vary by vehicle age and find that fluctuations in purchase prices of younger vehicles imply that buyers whose fuel price expectations mirror the petroleum futures market value a higher fraction of

future fuel costs: 93 percent% for one- to three-year-old vehicles, compared to their estimate of 76 percent% for all used vehicles assuming the same price expectation.¹⁵⁴⁷

Accounting for differences in their data and estimation procedures, the three studies described here suggest that car buyers who use discount rates of five to six percent value at least half—and perhaps all—of the savings in future fuel costs they expect from choosing models that offer higher fuel economy. Perhaps more important in assessing the case for regulating fuel economy, one study (Busse et al., 2013) suggests that buyers of *new* cars and light trucks value three-quarters or more of the savings in future fuel costs they anticipate from purchasing higher-mpg models, although this result is based on more limited information.

In contrast, previous regulatory analyses of fuel economy standards implicitly assumed that buyers undervalue even more of the benefits they would experience from purchasing models with higher fuel economy, so that, without increases in fuel economy standards, little improvement would occur, and the entire value of fuel savings from raising CAFE standards represented private benefits to car and light truck buyers themselves. For instance, in the EPA analysis of the 2017-2025 model year CO₂ standards, fuel savings alone added up to \$475 billion (at three percent discount rate) over the lifetime of the vehicles, far outweighing the compliance costs: \$150 billion). The assertion that buyers were unwilling to take voluntary advantage of this opportunity implies that collectively, they must have valued less than a third (\$150 billion/\$475 billion = 32 percent%) of the fuel savings that would have resulted from those standards. In fact, those earlier analyses assumed that new car and light truck buyers attach relatively little value to higher fuel economy, since their baseline scenarios assumed that fuel economy levels would not increase in the absence of progressively tighter standards, despite increasing fuel prices. The evidence reviewed here makes that perspective extremely difficult to justify and would call into question any analysis that claims to show large private net benefits for vehicle buyers attributable to increases in fuel economy standards.

What analysts assume about consumers' vehicle purchasing behavior, particularly about potential buyers' perspectives on the value of increased fuel economy, clearly matters a great deal in the context of benefit-cost analysis for fuel economy regulation. In light of this recent evidence on this question, warrants a more nuanced approach that is more nuanced than merely assuming that buyers drastically undervalue benefits from higher fuel economy, (and that, as a consequence, these benefits are unlikely to be realized without stringent fuel economy standards,) seems warranted. One possible approach would be to use a baseline scenario where fuel economy levels of new cars and light trucks reflected full (or nearly so) valuation of fuel savings by potential buyers in order to reveal whether setting fuel economy standards above market-determined levels could produce net social benefits. Another might be to assume that, unlike in the agencies' previous analyses, where buyers were assumed to greatly to undervalue

¹⁵⁴⁷ Allcott & Wozny (2014) and Saltee, et al. (2016) also find that future fuel costs for older vehicles are substantially undervalued (26-30%). The pattern of Allcott and Wozny's results for different vehicle ages is similar when they use retail transaction prices (adjusted for customer cash rebates and trade-in values) instead of wholesale auction prices, although the degree of valuation falls substantially in all age cohorts with the smaller, retail price based sample.

higher fuel economy under the baseline but to value it fully under the proposed standards, buyers value improved fuel economy identically under both the baseline scenario and with stricter CAFE standards in place.

The agencies requested comment on the consumer valuation of fuel economy and its use in the NPRM analysis. CBD and the North Carolina Department of Environmental Quality took issue with the agencies' characterization of the literature on the value of fuel economy, citing EPA's previous determination that the estimates in the literature represented too large a range, and the degree of uncertainty made including a value of fuel economy challenging. This final rule analysis accounts for the value of fuel economy in several places, though it uses a more conservative value than is suggested by the literature summarized above. Manufacturers have consistently told the agencies that new vehicle buyers will pay for about 2 or 3 years' worth of fuel savings before the price increase associated with providing those improvements begins to impact affect sales. We have assumed the same valuation, 2.5 years, in all components of the analysis that reflect consumer decisions regarding vehicle purchases and retirements.¹⁵⁴⁸ This analysis explicitly assumes that: 1) consumers are willing to pay for fuel economy improvements that pay back within the first 2.5 years of vehicle ownership (at average usage rates); 2) manufacturers know this and will provide these improvements even in the absence of regulatory pressure; 3) potential buyers weigh these savings against increases in new vehicle prices when deciding to retire a vehicle; and 4) the amount of technology for which buyers will pay rises (or falls) with rising (or falling) fuel prices.¹⁵⁴⁹ Excluding the value of fuel economy entirely from these calculations does not remove it from the analysis; it merely imposes an implausibly low value on the desired payback period of new vehicle buyers and manufacturers — regardless of fuel prices or technology costs. And while the agencies acknowledge the uncertainty around the estimates in the literature, zero is far removed from the lower bounds of any study.

CARB asserted that the various market failures alleged by the agencies in past rules (lack of information about fuel savings from higher MPG, inability to calculate cost savings from higher MPG, loss aversion, first-mover disadvantage), together with advertising that only emphasizes fuel economy during periods of high fuel prices, leads buyers to undervalue fuel economy.¹⁵⁵⁰ In contrast, CARB (and others—such as SCAQMD, Alliance to Save Energy, Save EPA, AAA, Environmental group coalition, Consumers Union, EDF, and IPI) argues elsewhere that new vehicle buyers *do* value fuel economy highly, and nearly fully once fuel

¹⁵⁴⁸ When accounting for social benefits and costs associated with an alternative, the full lifetime value of fuel savings is included.

¹⁵⁴⁹ NADA, the Alliance of Automobile Manufacturers, and American Fuel and Petrochemical Manufacturers argued that CAFE/CO₂ standards have already reached the point where the price increases necessary to recoup manufacturers' increased costs for providing further increases in fuel economy outweigh the value of fuel savings, and requiring further increases in fuel economy will reduce new vehicle sales. The sales response in the final rule recognizes and incorporates the effect of fuel prices and fuel economy on new vehicle purchases. *See* NADA, NHTSA-2018-0067-12064, at 11; Auto Alliance, Full Comment Set, NHTSA-2018-0067-12073 at 163-64; AMFP, Comments, NHTSA-2018-0067-12078-29, at 3.

prices return to “normal” levels.¹⁵⁵¹ The agencies’ payback period assumption, and the matching adjustment it makes to changes in new car prices to account for accompanying changes in fuel economy, recognizes that on average potential car buyers value a significant share of lifetime cost savings resulting from higher fuel economy. The agencies considered longer payback periods along the lines suggested by Consumer Federation of America (CFA),¹⁵⁵² but chose 2.5 years as a conservative approach. Our assumption is consistent with survey evidence cited by the commenters, but at odds with their assertions that this program is necessary to save buyers from their own limited ability to make decisions in their best interest.

More recently, the agencies have justified stricter CAFE and CO₂ emissions standards by asserting that buyers do not take advantage of opportunities to improve their *own* well-being, by purchasing models whose higher fuel economy would more than repay their higher initial purchase prices via future savings in fuel costs. This newer rationale is fundamentally different from asserting that some externality—whereby buyers’ choices cause economic harm to *others*—exists to justify regulating fuel economy or CO₂ emissions, or adopting more demanding regulations. EPA and NHTSA have previously labeled this behavior an example of the “energy paradox,” whereby consumers voluntarily forego investments that conserve energy even when those initial outlays appear likely to repay themselves—in the form of savings in energy costs—over the relatively near term.¹⁵⁵³

However, recent research cast doubt on whether such an energy paradox exists in the case of fuel economy—that is, on whether buyers of new vehicles inadequately consider the value of future savings in fuel costs they would experience from purchasing models that feature higher fuel economy—and about how extensive it might be. Several recent studies have estimated the fraction of appropriately discounted lifetime fuel savings offered by models featuring higher fuel economy that car shoppers appear to value or willing to pay for. These estimates are typically drawn from one of three sources—(1) buyers’ choices among competing models with different purchase prices, fuel economy levels, and other features; (2) statistically “decomposing” vehicle prices into the values buyers attach to their individual features, one of which is fuel economy; or (3) analyzing how selling prices for vehicles with different fuel economy levels respond to variation in fuel prices and the changes it causes in their lifetime fuel costs.

The estimates these studies report may partly reflect variation among buyers’ preferences for different vehicle features (such as fuel economy, but also size or utility), the financial

¹⁵⁵¹ *E.g. id.* at 190-91. *See also, id.* at 188-89. *See also*, SCAQMD, Supplemental comments, NHTSA-2018-0067-11813, at 4-5; Alliance to Save Energy, Comment, NHTSA-2018-0067-11837, at 2; Save EPA, Comments, NHTSA-2018-0067-11930, at 6; AAA, Comments, NHTSA-2018-0067-11979, at 2-3; Environmental group coalition, Appendix A, NHTSA-2018-0067-12000, at 54-56; Consumers Union, Attachment A, NHTSA-2018-0067-12068, 27-29; EDF, Appendix B, NHTSA-2018-0067-12108, at 84-86; and IPI, Appendix, NHTSA-2018-0067-12213, at 40-47.

¹⁵⁵² CFA, Comments, NHTSA-2018-0067-12005, at 12.

¹⁵⁵³ *See, e.g.*, EPA Regulatory Impact Analysis: Final Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, available at <https://nepis.epa.gov/Exe/ZyPDF.cgi/P100EZI1.PDF?Dockey=P100EZI1.PDF>.

constraints they face, how much they drive, or their expectations about future fuel prices, so they should be interpreted cautiously. However, the most careful recent studies suggest that on average buyers appear to undervalue the savings from higher fuel economy at most modestly, and perhaps not at all, after accounting for the influence of vehicles' other attributes on prices and purchasing decisions.¹⁵⁵⁴ This research suggests that the energy paradox, sometimes described as buyers' "myopia" in assessing the value of future fuel savings, is a much weaker rationale for regulating fuel economy than the agencies had previously asserted.

IPI commented that the agencies' obligation to consider market failures in setting standards derives not just from Executive Order 12,866 but also from the agencies' respective statutes, and argued that the agencies had defined market failures too narrowly in their proposal.¹⁵⁵⁵ Specifically, IPI stated that NHTSA's task under EPCA is "not so restricted to only protecting consumers from gas price spikes," and argued that NHTSA must also consider "externalities relating to energy security, national security, positional goods, global climate change, and air and water pollution associated with fuel production and consumption; asymmetric information, attention costs, and other information failures; internalities, including myopia; and various supply-side market failures, including first-mover disadvantage."¹⁵⁵⁶

For EPA's task under the CAA, IPI stated that, although while EPA must "protect the planet from unchecked climate change, [it] must not ignore other related market failures that cause harm to public health and welfare, including the issues and market failures [as described for NHTSA above]."¹⁵⁵⁷ IPI argued that the proposal was arbitrary and capricious for not "consider[ing] important aspects of the problem set before the agencies by Congress," and also for not considering the market failures discussed in the 2012 final rule.¹⁵⁵⁸ CBD, *et al.*, asserted similarly that the agencies' respective statutes require their actions to be more technology-forcing than what markets would otherwise achieve, in effect asserting that innovations in technology confer external benefits that vehicle manufacturers or buyers do not fully consider.¹⁵⁵⁹

With regard to the specific market failures CAFE and CO₂ standards could potentially address, Global Automakers suggested that climate effects are indeed an externality that more stringent standards can address,¹⁵⁶⁰ while CFA stated that regulating fuel economy and CO₂ emissions can address an extensive catalog of market failures, including externalities, marketing, availability of fuel-efficient models, transaction cost friction, information asymmetry, behavioral

issues, and access to capital, among others.¹⁵⁶¹ CFA asserted that advances in economic theory had heavily criticized the neoclassical model, and that “a great deal of empirical evidence supports [that the] standards are seen as an important and, in many ways, preferred policy approach.”¹⁵⁶² On this basis, CFA stated that attribute-based standards that “are set at a moderately aggressive level” and are “consistent with the rate of improvement that the auto industry achieved in the first decade of the fuel economy standard setting program,” among other things, would address the market failure.¹⁵⁶³

IPI argued that regulation of fuel economy (presumably also CO₂ emissions) is necessary because “many vehicle attributes, like horsepower and size, are positional goods—that is, they confer status on buyers of cars and light truck models that feature them prominently, so regulation of fuel economy can help correct the positional externality.”¹⁵⁶⁴ IPI also noted the externality of health effects associated with refueling. IPI cited Alcott and Sunstein (2015) to argue, like CFA, that fuel economy standards can correct market failures like informational failure, myopia, supply-side failures, positional externalities, etc., and by doing so, can provide net private welfare gains—that is, improve the utility of vehicle buyers *themselves*, not just that of *other* households or businesses.¹⁵⁶⁵

EDF and CARB both asserted that an energy paradox exists in the case of fuel economy, with EDF arguing (like CFA) that information asymmetry—that is, unequal access of vehicle manufacturers and potential buyers to information about the cost savings likely to result from owning higher-mpg models—coupled with limited availability of fuel-efficient models, leads consumers to purchase vehicles with lower fuel economy than they otherwise would.¹⁵⁶⁶ CARB simply stated that the NPRM analysis did not account for the energy paradox.¹⁵⁶⁷

The agencies agree with these commenters that the market failures CAFE and CO₂ standards can help address are likely to exist, but note that little of the behavior in the broad catalog identified by commenters actually represents market failures, and instead simply reflects consumers’ preferences for features other than fuel economy. Even in the few cases of potential market failures that commenters identify related to the hypothetical energy paradox, the agencies question whether more stringent CAFE and CO₂ standards are necessary to address the phenomena, or are even likely to be effective in doing so. In the agencies’ view, neither the

¹⁵⁶⁴ IPI, Appendix, NHTSA-2018-0067-12213, at 33.

¹⁵⁶⁵ *Id.* at 34. Note, however, that the reference cited does *not* address the question of whether fuel economy standards can be effective in correcting those market failures. Instead, it explores the circumstances under which fuel economy standards can improve welfare when vehicle buyers undervalue savings in fuel costs from purchasing more fuel-efficient models. See generally, Alcott, Hunt, and Cass R. Sunstein, “Regulating Internalities,” Working Paper 20087, National Bureau of Economic Research, May 2015, available at <https://www.nber.org/papers/w21187.pdf>.

¹⁵⁶⁶ EDF, Appendix B, NHTSA-2018-0067-12108, at 88-89.

¹⁵⁶⁷ CARB, Detailed Comments, NHTSA-2018-0067-11873, at 188-89.

logical arguments nor the limited empirical evidence that commenters presented convincingly demonstrate the capacity of more stringent CAFE and CO₂ standards to resolve, or even mitigate, most of the various phenomena they describe as market failures.

For example, the idea that regulating fuel economy and CO₂ emissions can mitigate the consequences of inadequate access to information by placing decisions that depend on access to complete information in the hands of regulators rather than buyers has superficial appeal. Yet commenters do not establish that such a drastic step is necessary to overcome any inadequacy of information, or that requiring manufacturers to supply higher fuel economy will be more effective than less intrusive approaches such as expanding the range of information available to buyers. As OMB Circular A-4 notes, “Because information, like other goods, is costly to produce and disseminate, your evaluation will need to do more than demonstrate the possible existence of incomplete or asymmetric information.”¹⁵⁶⁸

In the few cases where commenters cited empirical evidence to support their arguments that stricter fuel economy and CO₂ regulations are an appropriate response to market failures, that evidence is limited and unpersuasive. As one illustration, the frequent assertion that buyers’ widespread aversion to the prospect of financial losses makes them hesitant to purchase higher-mpg models appears to be traceable to findings from classroom experiments on small numbers of university students, rather than to large-scale empirical evidence drawn from buyers’ observed behavior.¹⁵⁶⁹ Commenters’ repeated emphasis on loss aversion as a critical source of buyers’

¹⁵⁶⁸ Circular A-4, at 5.

¹⁵⁶⁹ CFA, Comments, NHTSA-2018-0067-12005, at 16 *et seq*; Consumers Union, Attachment 4, NHTSA-2018-0067-12068, at 12; Attachment 3, NHTSA-2018-0067-11741, at 5-6, CARB at 214, and States at 87 each assert that loss aversion is an important source of car buyers’ hesitance to purchase higher-mpg models, variously citing Greene, David L., John German, and Mark A. Delucchi, “Fuel Economy: The Case for Market Failure,” *Reducing Climate Impacts in the Transportation Sector*, Springer in James S. Cannon and Daniel Sperling, eds., Springer, 2009, at pp. 181-205; (2009); Greene, David L. (2010). How consumers value fuel economy: A literature review (No. EPA-420-R-10-008); Greene, David L., “Uncertainty, Loss Aversion and Markets for Energy Efficiency”, *Energy Economics*, vol. 33, at pp. 608-616, (2011) and Greene, David L., “Consumers’ Willingness to Pay for Fuel Economy: Implications for Sales of New Vehicles and Scrappage of Used Vehicles,” attachment to comments by CARB, Oct. 10, 2018. However, none of these sources presents empirical evidence on how the frequency of actual common loss aversion actually is among real world vehicle buyers, instead simply asserting (or implicitly assuming) that loss aversion it is likely to be widespread. Further, their (identical) estimates of the *degree* of loss aversion are difficult to trace, and appear to be drawn from classroom exercises administered to limited numbers of university students, not from empirical research involving real world vehicle buyers. One source cited for their repeated assertion that losses of a given dollar amount are valued twice as highly as gains of the same amount is Gal, David, “A psychological law of inertia and the illusion of loss aversion,” *Judgment and Decision Making*, Vol. 1, No. 1, at pp. 23-32 (July 2006.), pp. 23–32, but this reference does not report such a value. Another source repeatedly cited by Greene and co-authors, Benartzi, Shlomo, and Richard H. Thaler, “Myopic Loss Aversion and the Equity Premium Puzzle,” *Quarterly Journal of Economics*, Vol. 110, No. 1, at pp. 73-92 (February 1995), pp. 73-92, does report this value (at p. 74), although only in passing, and cites other references as its original source. The original sources of the claim that losses are valued twice as highly as equivalent gains appear to be Kahneman, Daniel, Jack L. Knetsch, and Richard H. Thaler, “Experimental Tests of the Endowment Effect and the Coase Theorem,” *Journal of Political Economy*, Vol. 98, No. 6, pp. 1325-48. (Dec., 1990) (pp. 1325-1348, specifically Section II), pp. 1329-1336; and Tversky, Amos, and Daniel Kahneman, “Loss Aversion in Riskless Choice: A Reference-Dependent

unwillingness to choose levels of fuel economy that appear to be in their own financial interest also ignores recent research questioning whether loss aversion is a plausible motivation for such systematic or universal behavior by consumers.¹⁵⁷⁰

Another example is commenters' repeated citation of the study of households' difficulties in analyzing the financial value of purchasing vehicles with higher fuel economy conducted by Turrentine and Kurani, which relies on interviews with a limited number of subjects (57 California households) to conclude that consumers are systematically unable to perform the calculations necessary to estimate the value of fuel savings.¹⁵⁷¹ These same commenters consistently ignore the wealth of detailed, publicly-available information on the fuel economy of new vehicle models, and shoppers' ready access to user-friendly tools to estimate the savings they are likely to realize from purchasing higher-mpg models. These tools include the label that prominently displays how much a vehicles' fuel economy will save, or conversely, cost a purchaser in fuel costs over 5 years of use in color and large type (see Figure VI-55Figure I-4), which is legally required to be prominently displayed on all new cars vehicles offered for sale.¹⁵⁷² Separately, new car dealers are also required to prominently display the Federal Fuel Economy Guide for each model year of new vehicles offered for sale, which provides fuel economy information for all vehicles from that model year.¹⁵⁷³

Model," Quarterly Journal of Economics, Vol. 106, No. 4, at pp. 1039-61 (Nov., 1991) (pp. 1039-1061, specifically pp. 1053-1054). Neither of these references, however, makes any claim about the generality of the estimate or its applicability to non-experimental settings for consumer behavior.

¹⁵⁷⁰ See Gal, David, "A psychological law of inertia and the illusion of loss aversion," Judgment and Decision Making, Vol. 1, No. 1, pp. 23-32 (July 2006), pp. 23-32.; Erev, I., E. Ert, and E. Yechiam, "Loss aversion, diminishing sensitivity, and the effect of experience on repeated decisions.," Journal of Behavioral Decision Making, Vol. 21 (2008), pp. 575-597; (2008); Ert, E., and I. Erev, "On the descriptive value of loss aversion in decisions under risk: Six clarifications," Judgment and Decision Making, Vol. 8 (2013), at pp. 214-235; (2013); Gal, David and Rucker, Derek, "The Loss of Loss Aversion: Will It Loom Larger Than Its Gain?" Journal of Consumer Psychology, Vol. 28 No. 3, (July 2018), at pp. 497-516 (July 2018) available at (<https://onlinelibrary.wiley.com/doi/abs/10.1002/jcpy.1047>); and Gal, David, "Why the Most Important Idea in Behavioral Decision-Making Is a Fallacy," Scientific American, Observations, (July 31, 2018), available at (<https://blogs.scientificamerican.com/observations/why-the-most-important-idea-in-behavioral-decision-making-is-a-fallacy/>).

¹⁵⁷¹ ICCT at p. 4 and Consumers Union at p. 12 (among others), citing Turrentine, T. S., & Kurani, K. S., "Car buyers and fuel economy?", Energy policy, Vol. 35 No. 2 (2007), at 1213-1223, available at <https://www.sciencedirect.com/science/article/pii/S0301421506001200>, as evidence that most or all new-car shoppers are incapable of calculating the savings they would realize from purchasing a higher-mpg model, and further misinterpret the study as evidence that buyers invariably underestimate the value of increased fuel economy. Yet this widely relied-upon analysis included only 57 households, all located in California. As an illustration, citing Turrentine and Kurani, ICCT asserts "There is substantial circumstantial evidence that *most consumers in the U.S.* place a low value on fuel economy." See ICCT at 4 (emphasis added). Similarly, Consumers Union simply asserts that "Households do not track gasoline prices over time and cannot accurately estimate future gas prices or cost savings." See Consumers Union at 12, again citing Turrentine and Kurani as authority).

¹⁵⁷² See 15 U.S.C. 1531, *et seq.*, and 49 CFR 575.401.

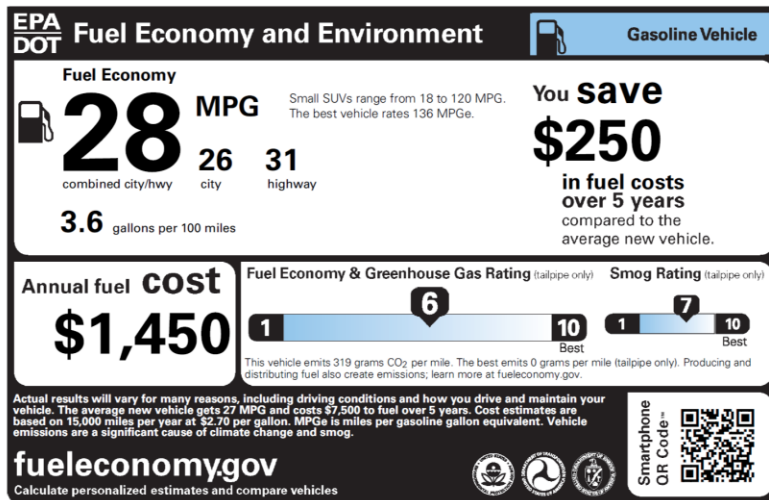

Figure II-2455 - Fuel Economy and Environment Label Example

Similarly, no commenters offered empirical evidence to support their repeated assertions that buyers or the public actually view features such as styling, size, or performance as “positional goods” to which other potential buyers might aspire, or considered the possibility that high fuel economy or advanced technology (such as hybrid or electric propulsion) might *themselves* represent such positional attributes.¹⁵⁷⁴ Nor do commenters provide any empirical evidence that the various aspects of behavior they allege lead buyers to underinvest in fuel economy—ranging from unwillingness to spend time or effort estimating likely fuel savings, to inattentiveness to the economic and social importance of improved fuel economy, inability to obtain information about the savings it offers them, and incorrect “framing” of the choice among

¹⁵⁷⁴ For evidence that prestige appears to be a motivation for purchasing advanced-technology vehicles, see Hidrue, Michael K., et al., “Willingness to pay for electric vehicles and their attributes,” *Resource and Energy Economics*, Vol. 33, Issue 3 (September 2011), at pp. 686-705; Chua, Wan Ying, Lee, Alvin and Sadeque, Saalem 2010, “Why do people buy hybrid cars?,” *Proceedings of Social Marketing Forum*, University of Western Australia, Perth, Western Australia, Edith Cowan University, Churchlands, W.A., at pp. 1-13; Liu, Yizao, “Household demand and willingness to pay for hybrid vehicles,” *Energy Economics*, Volume 44, 2014, at pp. 191-197; Hur, Won-Moo, Jeong Woo, and Yeonshim Kim, “The Role of Consumer Values and Socio-Demographics in Green Product Satisfaction: The Case of Hybrid Cars,” *Psychological Reports*, Volume 117, issue 2, October 2015, at pp. 406-427. A useful summary of many studies appears in Table 1 (p. 196) of Makoto Tanaka, Takanori Ida, Kayo Murakami, Lee Friedman, “Consumers’ willingness to pay for alternative fuel vehicles: A comparative discrete choice analysis between the US and Japan,” *Transportation Research Part A: Policy and Practice*, Volume 70, 2014, at pp. 194-209 (Table 1 at p. 196). Some of these studies find that buyers are apparently willing to pay significant price premiums for the prestige or status value of hybrids or battery-electric vehicles—which their authors speculate may derive from their “greenness”—because their purchases cannot be explained on the basis of economic or financial considerations. Others find that average or typical shoppers’ willingness to pay advanced-technology vehicles is below the price premiums they command, suggesting that their purchasers must derive some status or prestige value from owning and driving them.

models with different levels of fuel economy—are widespread, empirically significant, or systematically likely to lead buyers to under- rather than over-invest in fuel economy.

The most frequent argument that an energy paradox or energy efficiency “gap” exists in the case of fuel economy is the observation that many U.S. vehicle buyers seem unwilling to pay higher prices for models whose increased fuel economy would appear to repay their additional investment within a relatively brief ownership period. However, this argument is unpersuasive for at least three reasons: most obviously, it does not acknowledge the possibility that engineering studies systematically underestimate costs to produce vehicles with higher fuel economy, and thus the prices that buyers would be asked to pay for models with improved fuel economy. Nor does it account for potential sacrifices in *other* vehicle attributes that manufacturers may make in order to achieve higher fuel economy without increasing vehicles’ purchase prices beyond consumers’ willingness to pay. Finally, claims that consumers are acting irrationally by refusing to purchase higher-mpg models usually reach this conclusion by comparing rates at which they implicitly discount future fuel costs—and thus evaluate savings from purchasing more fuel-efficient models—to interest rates in financial markets that incorporate time horizons or risk profiles that may be very different from those of consumers.

Even putting these concerns aside, comparing future fuel savings to the costs of purchasing more expensive models that offer higher fuel economy demonstrates only that buyers are not behaving as analysts *expect them to* and *believe they should* behave. These comparisons do not demonstrate that consumers are necessarily acting irrationally, and cannot diagnose the nature of information shortcomings buyers face, reasons that they might interpret such information incorrectly, or identify behavioral inconsistencies they may exhibit. In short, conjectures about why buyers *might* undervalue potential savings from investing in higher-efficiency vehicle models do not represent evidence that they actually *do so*, and as discussed above, recent research seems to show that such behavior is not widespread, if it exists at all.

Past joint rulemaking efforts by NHTSA and EPA have repeatedly sought to identify a plausible explanation for car buyers’ perceived undervaluation of improved fuel economy. The agencies have occasionally relied on explanations such as consumers’ insufficient appreciation of the importance of fuel economy, the difficulty of obtaining adequate information about the fuel economy of competing models or of converting competing models’ fuel economy ratings to future fuel costs and savings, or consumers’ misunderstanding or mistrust of such information when it is provided to them. At other times, the agencies have pointed to consumers’ “myopia” about the future—asserting that for some reason, they appear to underestimate future fuel costs and savings—or argued that shoppers are insufficiently attentive to fuel costs when comparing competing models, that the value of improved fuel economy is obscured (“shrouded”) by vehicles’ other, more visible attributes, or that uncertainty about the savings in fuel costs owners will actually realize causes them to undervalue those savings when comparing the upfront costs of models with different fuel economy.

Despite the frequency with which the agencies have cited these hypotheses, clear support for any of them remains elusive. Consumers have long had ready access to detailed information about individual models’ fuel economy, which appears prominently on the labels displayed by

new cars,¹⁵⁷⁵ and is published online and in printed outlets that shoppers use routinely rely widely on to compare models.¹⁵⁷⁶ In addition, the fuel economy actually experienced by previous buyers of individual models is increasingly reported in readily accessible on-line databases.¹⁵⁷⁷

Similarly, consumers appear to be well aware of the prices they pay for gasoline and how those vary among retail outlets, and are reminded clearly and frequently of the financial consequences of their fuel economy choices each time they purchase fuel. Increasingly, consumers also have ready online access to comparisons of fuel prices at competing locations near their homes or along routes they travel.¹⁵⁷⁸ There is also considerable evidence that drivers' forecasts of future fuel prices are more accurate than those issued by government agencies or private forecasting services.¹⁵⁷⁹ Evidence exists that car buyers and owners anticipate extreme

¹⁵⁷⁵ Fuel economy labels have been displayed on the window sticker of all new light duty cars and trucks since the mid-1970s, as required by the Energy Policy and Conservation Act. See <https://www.epa.gov/fueleconomy/history-fuel-economy-labeling>. Among the information *currently* required to be posted on the fuel economy label is both an estimated annual fuel cost for the vehicle, as well as an estimate of how that cost compares to the fuel cost over five years for an average new vehicle, so it is unclear what information consumers lack that prevents them from making an informed decision in this regard.

¹⁵⁷⁶ See, e.g., <http://www.fueleconomy.gov>, where consumers can find and compare the fuel economy (and greenhouse gas CO₂ and smog emissions) of different vehicle models across model years, as well as upload information about their own real-world fuel economy and compare it to other drivers.

¹⁵⁷⁷ See *id.*

¹⁵⁷⁸ See, e.g., Gas Buddy, available at www.gasbuddy.com.

¹⁵⁷⁹ Anderson *et al.* report evidence that consumers believe fuel prices are likely to remain constant in inflation-adjusted terms; see Anderson, Soren T., Ryan Kellogg, and James M. Sallee, "What do consumers believe about future gasoline prices?" *Journal of Environmental Economics and Management*, vol. 66 no. 3 (2013), at pp. 383-403. (2013). Other evidence generally supporting this view is reported by Allcott, Hunt, "Consumers' Perceptions and Misperceptions of Energy Costs," *American Economic Review: Papers & Proceedings*, Vol. 101 No. 3 (2011), at pp. 98-104, (2011), although Allcott finds that some fraction of consumers consistently believes that gasoline prices will rise in the future. In related research, Anderson *et al.* demonstrate that consumers' expectations that gasoline prices will return to their current levels, even after sudden and significant variation, is generally accurate; see Anderson, Soren T., Ryan Kellogg, James M. Sallee, and Richard T. Curtin, "Forecasting Gasoline Prices Using Consumer Surveys," *American Economic Review: Papers & Proceedings*, Vol. 101 No. 3 (2011), at pp. 110-14. (2011). In contrast to many consumers' expectation that fuel prices may vary over the future but will generally return to current levels, the U.S. Energy Information Administration predicted that gasoline prices would rise significantly over the future at the time the two previous rules establishing CAFÉ standards for model years 2012-16 and 2017-21 were adopted, in 2010 and 2012; see Energy Information Administration (EIA), *Annual Energy Outlook 2010*), Table A12, p. 131, available at [https://www.eia.gov/outlooks/archive/aeo10/pdf/0383\(2010\).pdf](https://www.eia.gov/outlooks/archive/aeo10/pdf/0383(2010).pdf), Table A12, p. 131; and *Annual Energy Outlook 2012*, Appendix A, Table A12, at p. 155, available at <https://www.eia.gov/outlooks/archive/aeo12/pdf/appa.pdf>, Table A12, p. 155. As of those same dates, forecasts of future petroleum prices issued by other government agencies and most private forecasting services (with the notable exception of HIS-Global Insight, which projected little or no increase in future prices) agreed closely with EIA's forecasts that prices would increase significantly over both the near- and longer-term futures; see EIA, *Annual Energy Outlook 2010*, Table 10, at p. 86; and *Annual Energy Outlook 2012*, Table 23, available at https://www.eia.gov/outlooks/archive/aeo12/table_23.php. Expressed in constant-dollar terms, U.S. gasoline prices in 2019 are essentially unchanged from those in 2010, although prices have varied significantly above and below that level during the intervening period. See https://www.eia.gov/dnav/pet/hist/LeafHandler.ashx?n=p&s=emm_epm0_pte_nus_dpg&f=m.

volatility in fuel prices, recognize that there is considerable uncertainty about future fuel prices and potential savings from driving a higher-mpg model, and respond cautiously to these uncertainties when evaluating competing vehicle models,¹⁵⁸⁰ none of which suggests a market failure as much as it suggests that consumers balance multiple, often competing objectives, and make choices based on the outcome of such balancing.

In past rulemakings, the agencies have also hypothesized that consumers may “satisfice” — that is, select some minimum acceptable level of fuel economy, and then evaluate models that achieve that minimum on the basis of their other attributes. This explanation for buyers’ reluctance to purchase more fuel-efficient vehicles ignores the possibility that they do account fully for the value of higher fuel economy in their decision-making, but simply value differences in vehicles’ other attributes more highly than they do fuel economy, which would not reveal irrational or myopic behavior.

A related argument has been that calculating future savings attributable to fuel economy is complicated, so car shoppers resort to simplified decision rules to choose among models with different fuel economies, and relying on these rules-of-thumb causes them to choose models with lower fuel economy.¹⁵⁸¹ However, it is unclear why buyers’ reliance on simplified procedures or approximations for estimating the value of fuel savings would necessarily lead them to systematically choose models with *lower* fuel economies rather than leading some to underinvest in fuel economy while others overinvest.

The agencies have also frequently described consumers as “loss averse,” making them reluctant to pay the upfront and certain higher prices for models offering better fuel economy when the future savings they expect to realize are more distant and less certain.¹⁵⁸² The agencies’ past assumption that loss aversion is universal (and equally strong) among new-car shoppers appears to be a simplification that is largely unsupported by empirical evidence, and in any case has been challenged both as a widespread feature of consumer behavior and more specifically as an explanation for vehicle shoppers’ reluctance to purchase more costly models that offer higher fuel economy.¹⁵⁸³ Further, the extremely wide variety of competing models among which car buyers can choose enables many of those searching for a model with better fuel economy at a comparable price to do so simply by choosing a version with fewer other features, which might partly offset the effect of their aversion to the prospect of losses from paying a higher purchase price. Lastly, the agencies note that *both* increased fuel costs and increased

¹⁵⁸⁰ For such evidence, see Allcott, Hunt, “Consumers’ Perceptions and Misperceptions of Energy Costs,” *American Economic Review: Papers & Proceedings*, Vol. 101 No. 3 (2011), at pp. 98–104; (2011); Greene, David L., (2010). “How consumers value fuel economy: A literature review” No. EPA-420-R-10-008 (2010) (No. EPA-420-R-10-008); Brownstone, David, David Bunch, and Kenneth Train, “Joint Mixed Logit Models of Stated and Revealed Preferences for Alternative-Fuel Vehicles,” *Transportation Research Part B*, Vol. 34 (2000), at pp. 315-338, (2000), among many other sources.

¹⁵⁸¹ See, e.g., 77 FR at 63115 (Oct. 15, 2012).

¹⁵⁸² *Id.* at 63114–15; see also 74 FR at 25511, 25653 (May 7, 2010).

¹⁵⁸³ See *supra* notes 156948 and 157049.

upfront car prices will appear as “losses,” so it is not obvious why potential buyers would react to the prospects of these different forms of losses in different ways.

OMB Circular A-4 does acknowledge that “[e]ven when adequate information is available, people can make mistakes by processing it poorly.” It goes on to say that people may rely on “mental rules-of-thumb” that produce errors, or cognitive “availability” may lead to consumers overstating the likelihood of an event. However, Circular A-4 also cautions that “the mere possibility of poor information processing is not enough to justify regulation,” and that potential problems with information processing “should be carefully documented.” Some of the above examples of potential market failures may fall into this category, but lack evidentiary support. As with claims of asymmetric information, it is very difficult to distinguish between information processing errors and behavior consistent with consumer preferences for time and other vehicle attributes that differ from what government agency analysts *believe* they should be.

Similarly, the agencies have occasionally noted (and seemingly been critical of) some consumers’ apparent preferences for vehicle attributes that convey social status, such as size or styling, and suggested that they may give inadequate attention to fuel economy because it does not provide similar status. The agencies have also suggested that consumers may be reluctant to purchase more fuel-efficient models because they associate higher fuel economy with inexpensive, less well-designed vehicles. These might be plausible explanations, were they not contradicted by concurrent arguments that potential buyers are inattentive to or uninformed about fuel economy, or have difficulty isolating it from vehicles’ other attributes. Moreover, the market currently offers a wide range of highly fuel efficient (and advanced technology) vehicles at many different price points, including in the luxury and performance segments, which belies the assumption that fuel economy is inconsistent with positional attributes. In any case, consumers’ hesitance to choose models offering higher fuel economy because they are reluctant to sacrifice improvements in other vehicle attributes on which they place higher values cannot reasonably be characterized as a market failure.

Although past rulemakings have raised the possibility that car buyers’ apparent tendency to underinvest in fuel economy could plausibly be explained by their use of discount rates exceeding those the agencies employ to assess the present value of fuel savings, the agencies have generally dismissed that possibility. In combination with factors such as their valuation of vehicles’ attributes other than fuel economy, differences in driving habits that affect fuel economy and in how much they expect to drive newly- purchased cars, and variation in their expectations about future fuel prices, differing attitudes about the importance of future costs relative to more immediate ones could readily explain buyers’ apparent reluctance to purchase models offering fuel economy levels that the agencies interpret as privately “optimal.”

As with consumption of any good or service, the agencies believe consumers’ choice in vehicles represents what economists call “constrained optimization.” That is, consumers select a bundle of vehicle features—within their budget constraint—that optimizes the value to them. The agencies also believe, as is the case in every constrained consumer choice, that each of these attributes provides what economists call diminishing marginal returns (or value) to consumers. For instance, the agencies believe that consumers value vehicle size, comfort, performance, trim-level, appearance, etc. As such, fuel-saving technologies that increase the cost of the car are just

one of many vehicle attributes that consumers balance against each other. And instead of using their entire budget on a single vehicle attribute, consumers tend to sacrifice some degree of many or all attributes in a degree that varies according to their preferences so that they can consume some degree of most or all attributes they value. This means that many consumers would not maximize fuel-saving technologies in their vehicle selection, but instead may choose some other bundle of attributes. The agencies' use of a 30 month pay-back period in this analysis—as opposed to fuel-savings over the life of the vehicle—is consistent with the constrained optimization consumers do in their vehicle selection. It is a reasonable approximation consumer's valuation of fuel-saving technologies, given diminishing marginal returns. If the agencies had used the entire undiscounted fuel-savings over the entire life of the vehicle, the agencies would be effectively modeling a scenario where consumers maximize fuel economy to the detriment of all other vehicle attributes—an assumption that is evidently wrong. As such, it is not necessarily that purchasers do not value lifetime fuel savings and would likely prefer a vehicle with better fuel efficiency and all of their preferred attributes, but rather consumers are forced to choose between fuel economy and other vehicle attributes while weighing how much each attribute costs.

The agencies recognize that it may seem contradictory to argue that purchasers correctly value the lifetime fuel savings from purchasing a vehicle that offers higher fuel economy, while at the same time using a payback period of only 2.5 years in their analysis, since the latter implies that buyers disregard fuel savings over the remainder of vehicles' expected lifetimes. However, assuming a 2.5-year payback period does not necessarily contradict the agencies' skepticism about the existence of an energy paradox in fuel economy, partly because as explained above, the future is highly uncertain. To accurately estimate the value of purchasing a higher-mpg model, a new-car shopper would need to know how long she expects to own the vehicle before selling it, how many miles she expects to drive each year over that time, how fuel prices will vary over that same period, and the price premium its higher fuel economy would command in the used car market at the time she expects to sell it. All of these factors are highly uncertain at the time buyers are contemplating their purchases, and subject to change over the time they own vehicles they purchased when new. Recognizing this uncertainty, 2.5 years is likely to be a reasonable estimate of the period over which a typical rational consumer would have sufficient confidence to project the value of purchasing a model that offers higher fuel economy.

Furthermore, purchasing decisions are rarely made in isolation and are often constrained by household budgets. As noted in the proposal, at least one independent study indicated that the average new car price was unaffordable to median-income families in every metropolitan region in the United States except one: Washington, DC.¹⁵⁸⁴ The problem has only become more

¹⁵⁸⁴ Bell, C. What's an 'affordable' car where you live? The answer may surprise you, Bankrate.com (Jun. 28, 2017), available <https://www.bankrate.com/pdfs/pr/20170628-Car-Affordability.pdf> (last accessed March 5, 2020).

exacerbated as, by the end of 2018, new vehicle prices exceeded \$38,000¹⁵⁸⁵—up by \$4,000 since 2015 alone—while the median income rose to \$63,000¹⁵⁸⁶—an increase of only \$3,000 over the same time-period. And—as discussed in detail throughout this rule—some consumers may value other vehicle attributes more than fuel efficiency, and it would be rational for them to give up some lifetime fuel savings in exchange for other vehicle attributes. While consumers may prefer vehicles with higher fuel efficiency, they are just as likely to be unable to afford increased fuel economy and the other vehicle attributes they desire.¹⁵⁸⁷

Finally, the agencies have also previously speculated that vehicle producers may be reluctant to offer models featuring the higher levels of fuel economy that buyers are willing to pay for, and that buyers' apparent underinvestment in fuel economy reflects this lack of choice. The agencies have speculated that such behavior by manufacturers could arise from their collective underestimation of the value that buyers attach to fuel economy, or failing this, from limitations on competition among them to supply improved fuel economy, whether voluntarily or as a consequence of the industry's structure.¹⁵⁸⁸ The agencies have also raised the seemingly contradictory argument that producers have more complete knowledge about fuel economy than potential buyers ("asymmetric information") causing them to provide *lower* levels than buyers demand, and speculated that deliberate decisions by manufacturers may limit the range of fuel economy they offer in particular market segments.¹⁵⁸⁹

The overarching theme of these arguments seems to be that vehicle manufacturers cannot identify—or can, but voluntarily forego—opportunities to increase sales and profits at the expense of their rivals by offering models that feature higher fuel economy. The agencies have sometimes ascribed this behavior to the risk that producers might incur large investments to produce the more fuel-efficient models that would enable them to seize these opportunities, but subsequently lose sales and profits to competitors who simply followed suit after their rivals were successful. This explanation is at odds with the customary view that innovative producers can be rewarded—substantially, even if only temporarily—with commensurate profits that justify taking such risks, when they correctly assess consumer demand for innovative features or products.

In any case, behavior on the part of individual businesses that leaves obvious opportunities to increase profits unexploited *by an entire industry* seems extremely implausible,

¹⁵⁸⁵ See, e.g., *Average New-Vehicle Prices Up Nearly 2% Year-Over-Year in December 2019, According to Kelley Blue Book*, <https://mediaroom.kbb.com/2020-01-03-Average-New-Vehicle-Prices-Up-Nearly-2-Year-Over-Year-in-December-2019-According-to-Kelley-Blue-Book> (last accessed March 5, 2020).

¹⁵⁸⁶ Median Household Income data are from U.S. Census Bureau, Table A–2, Households by Total Money Income, Race, and Hispanic Origin of Householder: 1967 to 2018 (<https://www.census.gov/data/tables/2019/demo/income-poverty/p60-266.html>, last accessed March 5, 2020).

¹⁵⁸⁷ This is similar to the phenomena described in *The Bernie Mac Show: My Privacy* (Fox Broadcasting Company Jan. 14, 2005). After an embarrassing incident caused by too few bedrooms, Bernie Mac decides to renovate his house. A contractor tells Mr. Mack that he can have the renovations performed “good and fast,” “good and cheap,” or “fast and cheap”, but it was impossible to have “good, fast, and cheap.”

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

particularly in light of the fact that auto manufacturers are profit-seeking businesses whose ownership shares are publicly traded and subject to regular market valuation. This notion also seems to ignore the range of choices already available in the current automobile market, where extraordinarily efficient models are available in nearly every vehicle class or market segment, including plug-in hybrid and fully electric versions of a rapidly increasing number of models. Automobile manufacturers can, and in fact are, competing on the basis of fuel economy.

The central analysis presented in this final regulatory impact analysis does not account for the possibility that imposing stricter standards may require manufacturers to make sacrifices in other vehicle features that compete with fuel economy, and that some buyers may value more highly. If this proved to be the case, more stringent alternatives could impose offsetting losses on buyers well beyond the increases in vehicle prices that are necessary for manufacturers to recover their outlays for adding new technology (or changing design features) to improve fuel economy. By doing so, it could significantly reduce the estimates of total and net benefits the agencies report. To further illustrate this issue, we have conducted a sensitivity analysis that incorporates a conservative estimate of consumers' valuation of other vehicle attributes, as further discussed section VI.D.1.b.11.¹⁵⁹⁰ We also recognize that buyers may have time preferences that cause them to discount the future at higher rates than the agencies are directed to consider in their regulatory evaluations.

If either case is true – that the analysis is incomplete regarding consumer valuation of other vehicle attributes or discount rates used in regulatory analysis inaccurately represent consumers' time preferences – no market failure would exist to support the hypothesis of a fuel efficiency gap. In either case, the agencies' central analysis would overstate both the net private and social benefits from adopting more stringent fuel economy and CO₂ emissions standards. For instance, Table VII-97 [Combined LDV Societal Net Benefits for MYs 1975-2029, CAFE Program, 7% Discount Rate] shows that the CAFE final rule would generate \$16.1 billion in total social net benefits using a 7% discount rate, but without the large net private loss of \$26.1 billion, the net social benefits would equal the external net benefits, or \$42.2 billion. Because government action cannot improve net social benefits in the absence of a market failure, if no market failure exists to motivate the \$26.1 billion in private losses to consumers, the net benefits of these final standards would be \$42.2 billion.

In sum, the agencies do not take a position in this rule on whether a fuel efficiency gap exists or constitutes a failure of private markets. Accordingly, the final regulatory impact analysis is not constrained in any manner that ensures the private net benefits of more stringent standards will necessarily be either positive or negative. In fact, however, the analysis supporting this final rule *does* present a situation where adopting more stringent CAFE and CO₂

¹⁵⁹⁰ This sensitivity analysis assumes that consumer's value of other vehicle attributes is *at least as great as a portion* of the fuel savings that consumers supposedly "leave on the table." In this analysis, the private net benefits of the final rule are a positive \$15 billion using a 7% discount rate—which is consistent with the theory that providing consumers with greater choices will enhance their private welfare. The net external benefits are identical to the primary analysis, or \$34 billion, so the sensitivity results show the final rule improves net social benefits by \$49 billion.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

emission standards aligns consumers' decisions with a simplified representation of *their own economic interests*, and by doing so improves their well-being from what they would experience under less stringent standards. In other words, our final modelling results reflect the case where some fuel efficiency gap persists (albeit of smaller magnitude than the agencies found in previous analyses), despite our expressed reservations about its likelihood.

(b) *Representing sales responses in CAFE/ CO₂ analysis*

The approach used in the NPRM relied on a single model to produce the total number of new vehicle sales in each calendar year for a given regulatory scenario. Many commenters expressed reservations about the predictive capabilities of the model (CARB, North Carolina Department of Environmental Quality, EDF, Aluminum Association). As the Aluminum Association commented, “[D]eveloping a model to predict consumer reaction to changes in prices is complicated and highly sensitive to macroeconomic conditions, consumer confidence and employment levels.”¹⁵⁹¹ As discussed above, we agree that development of such a model is complicated, and the agencies have elected to simplify the approach for the final rule. For the purposes of regulatory evaluation, the relevant sales metric is the difference between alternatives rather than the absolute number of sales in any of the alternatives. As such and in response to these comments and others previously addressed, the agencies divided the sales response model for the final rule into two parts: a nominal forecast that provides the level of sales in the baseline (based primarily upon macroeconomic inputs), and a price elasticity that creates sales differences relative to that baseline in each year. The nominal forecast does not include price, and is merely a (continuous) function of several macroeconomic variables that are provided to the model as inputs. While the statistical model used in the NPRM attempted to account for the influence of these other factors in estimating the price elasticity, the forecast in this analysis separates the two completely (as described further below). The price elasticity is also specified as an input, but this analysis assumes a unit elastic response of -1.0—meaning that a one percent increase in the average price of a new vehicle produces a one percent decrease in total sales.¹⁵⁹²

The revised sales model features three broad changes: 1) it uses the change in average vehicle price net of fuel costs instead of vehicle prices on their own, 2) it uses macroeconomic factors to project baseline sales without considering vehicle prices, and 3) it assesses the change in sales across the various regulatory alternatives considered using an own-price elasticity from the literature. These changes were made in response to comments that consumers are willing to pay for some level of fuel economy and vehicle prices and sales are simultaneously and jointly determined (e.g. endogenous). This section discusses these three broad changes, as well as other more technical and minor changes.

The first component of the new sales response model is the nominal forecast, which is a function (with a small set of inputs) that determines the size of the new vehicle market in each

¹⁵⁹¹ NHTSA-2018-0067-11952-4.

¹⁵⁹² The “price increase” in this case represents the new vehicle price net of a portion of fuel savings, described further in this section.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

calendar year in the analysis for the baseline. It leverages some of the same structure of the statistical model used in the NPRM, though the dependent variable and some of the explanatory variables have changed. It is of some relevance that this statistical model is intended only as a means to project a baseline sales series. Some commenters raised econometric objections about the NPRM specification's ability to isolate the causal effect of new vehicle prices on new vehicle sales. The agencies note that the nominal forecast model does not include prices and is not intended for statistical inference.

The forecast is derived from a statistical model that accounts for a similar set of exogenous factors related to new light-duty vehicle sales. In particular, the model accounts for the number of households in the U.S., recent number of new vehicles sold, GDP, and consumer confidence. The structure of the forecast model is similar to the NPRM model, which also used a ARDL specification, but even the variables that are common between the two models have different structural forms in the final rule version. In particular, the dependent variable has been transformed to reflect the fact that, as some commenters suggested, households are an important component of demand for new vehicles. As such, the dependent variable is defined as new vehicles sold per household.¹⁵⁹³ While this variable still exhibits the cyclic behavior that new vehicle sales exhibit over time, the trend shows the number of new vehicles sold per household declining since the 1970's, as shown in [Figure II-25](#)~~Figure VI-50~~, where the dotted line is the trend over time. As this time series is non-stationary,¹⁵⁹⁴ a lagged variable (the value in the previous year) is included on the right-hand side of the regression equation. In Addition, the model includes a lagged variable that represents the three-year running sum of new vehicle sales, divided by the number of households in the previous year. This variable represents the saturation effect, where the existing number of households can only buy so many new vehicles before a significant number of households already have one (and do not need to buy another). As vehicle durability and cost has increased over time, and average length of initial ownership has increased similarly, this variable acts to put downward pressure on sales after successive years of high sales (particularly during extrapolation).

¹⁵⁹³ Number of U.S. households is taken from Federal Reserve Economic data, <https://fred.stlouisfed.org/series/TTLHH>.

¹⁵⁹⁴ Stationary refers to whether a time series statistical properties are constant over time. Since car sales are increasing over time, the time series non-stationary.

Figure II-2556 - New Light-Duty Vehicle Sales per Household in the United States, 1970 – 2016

Similar to the NPRM model, the forecast model includes real U.S. GDP,¹⁵⁹⁵ but in natural logarithm form (as some commenters suggested was more appropriate).¹⁵⁹⁶ The final variable is consumer sentiment, as measured by the University of Michigan survey of consumers.¹⁵⁹⁷ As both of these series are non-stationary (determined by applying augmented Dickey-Fuller unit root tests to the time series), lagged versions of the variables are included to ensure stationarity in the residuals. The functional form appears below in Equation 2.

Equation 2 - Statistical Model Used to Generate Nominal Forecast

$$\begin{aligned}
 \text{New_Veh_per_HH}_t &= C + \beta_1 \text{New_Veh_per_HH}_{t-1} + \beta_2 \text{3YrSumPerHH}_{t-1} + \beta_3 \text{LN}(\text{GDP}_t) \\
 &+ \beta_4 \text{LN}(\text{GDP}_{t-1}) + \beta_5 \text{Consumer_sentiment}_t \\

The model fit is described in [Table II-48](#)~~Table VI-128~~. The included lag term of the dependent variable and both GDP variables are statistically significant at nearly zero, while both the lagged three year sum term and consumer sentiment are both marginally significant. Being a time series model, we also computed the Durbin-Watson test statistic for autocorrelation (1.77) and the Breusch-Godfrey test for serial correlation (0.65) at order 1. The signs of the coefficients are all correct, in the sense that they are consistent with our expectations.

Table II-~~48~~[121](#) - Summary of Forecast Regression Function

	new.veh.per.HH

Because the dependent variable is the number of new vehicles sold per household, it is necessary to multiply by the number of households to produce an estimate of new vehicle sales. This model is used to produce a forecast of new vehicle sales out to 2050, so it is necessary to have projections of each variable used in [Equation 2](#)~~Equation-2~~ through calendar year 2050. In an effort to be consistent with other inputs to the analysis, the projection of U.S. GDP is taken from the 2019 AEO. The forecast of households in this analysis comes from the Harvard Joint Center for Housing Studies 2018 Household projections.¹⁵⁹⁸ The consumer confidence forecast is taken directly from the University of Michigan index for 2017 and 2018, and from the Global Insight forecast of consumer confidence for all subsequent years.

While the analysis could have relied on a forecast of new vehicle sales taken from a published source (the 2019 AEO, for example), using a function is an attractive option because it allows the CAFE Model dynamically to adjust the forecast in response to input changes. If a sensitivity case requires a forecast that is consistent with a set of specific, possibly unlikely, assumptions, a forecast of new vehicle sales that is consistent with those assumptions may not

¹⁵⁹⁸ <https://www.jchs.harvard.edu/research-areas/working-papers/updated-household-growth-projections-2018-2028-and-2028-2038>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

exist in the public domain, for example low GDP growth sensitivity cases. Using a functional form, as we have done here, allows the user to vary some of the assumptions to the analysis without creating inconsistencies with other elements of the analysis. However, it is incumbent upon the analyst to ensure that any set of assumptions that deviate from the central analysis are logically consistent.

This function, and the set of assumptions contained in the central analysis, produces a projection that is comparable in magnitude to the forecast in the 2019 AEO reference case, though there are differences. The two forecasts, and the percentage difference relative to the AEO 2019, appear in [Table II-49](#)~~Table VI-129~~, as does a recent forecast published by the Center for Automotive Research.¹⁵⁹⁹ The reader will notice that even 2017 shows a discrepancy of nearly 7 percent between the final rule forecast and the Annual Energy Outlook, one of the larger differences between annual forecasts. However, the final rule analysis is based upon the certified production volumes of MY2017, which exceed 17 million units. So, while the difference may seem significant, the final rule volumes in 2017 represent the ground truth for model year production.¹⁶⁰⁰ The CAR forecast, while shorter in length, is consistently higher than both the AEO and final rule forecasts—though likely also includes class 2b (and possibly class 3) pickup trucks in its light vehicle forecast. Finding a public forecast that explicitly excludes light-duty vehicles exempt from these regulations is challenging. However, all three forecasts exhibit similar trends—decreases in sales starting in 2019 that last for a few years before ticking up again slowly. As commenters observed, all forecasts are almost guaranteed to have some errors, and projections out to 2050 should be taken as potential future projections limited by our knowledge at the time, rather than an ironclad prediction of the future.

Table II-~~49~~[42](#) - Comparison of AEO2019 Projection to Final Rule (Million Vehicles)

Year	AEO 2019	Final Rule	Percent difference (AEO, final rule)	CAR

2050	16.72	15.72	-6.0	

Although the forecast produces the total number of new vehicle sales in the baseline, an elasticity is imposed on price differences to produce sales changes between alternatives. The NPRM version of the model considered only differences in average new vehicle prices between alternatives, and the agencies received a number of comments (from CBD, IPI, EDF, CARB, CA et al., and Oakland et al., as well as recent peer reviewers) encouraging the agencies to account for some component of fuel savings associated with those price changes. In their comment, California et al. and Oakland et al. stated the model failed “to consider how consumers will respond to the reduced cost of operating the vehicle from better gas mileage and therefore inaccurately predicts a decline in vehicle sales under the existing standards.”¹⁶⁰¹ The agencies agree that price is not the only consideration, and that the value of fuel savings to new vehicle buyers is also relevant to the purchase decision.

¹⁶⁰¹ States and Cities, Attachment 1, NHTSA-2018-0067-11735, at 86.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

In previous rules, while the agencies produced analyses that qualitatively considered sales and employment impacts, the agencies acknowledged that fuel economy and CO₂ standards were likely to increase vehicle prices, while simultaneously reducing operating costs, and that estimating how consumers would choose to balance those two factors in the new vehicle market was challenging.¹⁶⁰² Furthermore, the agencies recognized that there is a broad consensus in the economic literature that the price elasticity of demand for automobiles is approximately -1.0.¹⁶⁰³ The agencies feel that a unit elasticity of -1.0 is still a reasonable estimate.¹⁶⁰⁴

Because the elasticity assumes no perceived change in the quality of the product, and the vehicles produced under different regulatory scenarios have inherently different operating costs, the price metric must account for this difference. As commenters suggested is appropriate, the price to which the unit elasticity is applied in this analysis represents the residual price change *between scenarios* after accounting for 2.5 years' worth of fuel savings to the new vehicle buyer. This approach is consistent with the 2012 FRIA analysis of sales impacts, that which considered several payback periods over which the value of fuel savings was subtracted from the change in average new vehicle price.

Similar to the NPRM, the price elasticity is applied to the percentage change in average price (in each year). However, the average price to which the elasticity is applied is calculated differently in the final rule in response to comments. As discussed below the price change does not represent an increase/decrease over the last observed year, but rather the percentage change relative to the baseline. In the baseline, the average price is defined as the observed new vehicle price in 2017 plus the average regulatory cost associated with the alternative. In the case of CO₂ standards, the regulatory cost is equivalent to the retail equivalent price of technology improvements. In the case of CAFE standards, the regulatory cost includes both technology costs and civil penalties paid for non-compliance in a model year. So the change in sales for alternative *a* in year *y* is:

¹⁶⁰² Final Regulatory Impact Analysis, Corporate Average Fuel Economy for MY 2017-MY 2025 Passenger Cars and Light Trucks, August 2012, at 821

¹⁶⁰³ See, e.g., Kleit, A.N., "The Effect of Annual Changes in Automobile Fuel Economy Standards," *Journal of Regulatory Economics*, Vol. 2 (1990), at pp 151-72; Bordley, R., "An Overlapping Choice Set Model of Automotive Price Elasticities," *Transportation Research B*, Vol. 28B no. 6 (1994), at pp 401-408; and McCarthy, P.S. "Market Price and Income Elasticities of New Vehicle Demands," *The Review of Economics and Statistics*, Vol. LXXVII no. 3 (1996), at pp. 543-547.

¹⁶⁰⁴ For example, a recent review of 12 studies examining vehicle price elasticities conducted by the Center of Automotive Research ("CAR") found an "average short-run elasticity of -1.09" and focusing "only those models which also employ time series methods, the average short-run own-price elasticity is higher yet, at -1.25." CAR's own analysis found a -.79 short-run elasticity. Appendix II of the CAR report shows that the long-run elasticities ranged from -.46 and -1.2 with an average of -.72. In sum, a -1.0 elasticity is well-aligned with the totality of research. Equation 3 - Calculation of Change in Sales

$$\Delta Sales_{y,a} = \frac{(\Delta RegCost_{y,a-0} - \Delta FuelCosts_{t,a-0})}{34449 + RegCost_{y,0}} \cdot PriceElasticity \cdot NominalSales_y$$

$\Delta RegCost$ is the difference in average regulatory cost between alternative a and the baseline scenario in year y to make a vehicle compliant with the standards, \$34,449 is the average transaction price of a new vehicle in 2016, $NominalSales$ is the forecasted sales (in the baseline) in year y , $\Delta FuelCosts$ is the change in average fuel costs over 2.5 years relative to the baseline in year y and $PriceElasticity$ is -1.0:

Equation 4 - Change in Fuel Costs Used to Compute Sales Differences

$$\Delta FuelCosts_{t,a-0} = \left(\frac{FuelPrice_t}{NewVehFE_{t,a}} - \frac{FuelPrice_t}{NewVehFE_{t,0}} \right) * 35000$$

Where 35,000 miles is assumed to be equivalent to 2.5 years of vehicle usage.¹⁶⁰⁵ We assume that consumers behave as if the fuel price faced at the time of purchase is the fuel price that they will face over the first 2.5 years of ownership and usage. Essentially, they behave as if fuel prices follow a random walk, where the best prediction of (near) future prices is the price today. Odometer data show that typical usage of new vehicles is about 14,000 miles per year, and that scrappage rates in the first few years of ownership are close to zero, so buyers can reasonably expect to travel the full annual mileage in each of the first three years of ownership. Total sales in each alternative (that is not the baseline) will equal $NominalSales_y + \Delta Sales_{a,y}$ for alternative a in year y .

This implementation produces a range of differences in total sales, both between alternatives and over time.

¹⁶⁰⁵ Based on odometer data, 35,000 miles is a good representation of typical new vehicle usage in the first 2.5 years of ownership and use – though the distribution of usage is large.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

[Table II-50](#)~~[Table VI-130](#)~~ shows the range of differences in the final rule at the industry level for CO₂, and [Table II-51](#)~~[Table VI-131](#)~~ shows the sales changes under CAFE. While cost decreases between the baseline and alternatives differ by program, one can see that removing the value of fuel savings from the price limits the sales increases in the alternatives to under 300,000 units in a single year under the preferred alternative, and about one percent of total sales between 2017 and 2050.

[Table II-50](#)~~Table VI-130~~ and [Table II-51](#)~~Table VI-131~~ show sales under the baseline (aугural standards), and differences under the proposal (0 percent increase in stringency) and final rule (1.5 percent increase in stringency) of MYs 2017-2050.

Dynamic Fleet Share (DFS)

The first module described above (the forecast function and applied elasticity) determine the total industry sales in each model year from 2018 (in this analysis, 2017 is based on certified compliance data) to 2050. A second module, the dynamic fleet share, acts to distribute the total industry sales across two different body-types: “cars” and “light trucks.” While there are specific definitions of “passenger cars” and “light trucks” that determine a vehicle’s regulatory class, the distinction used in this phase of the analysis is more simplistic. All body-styles that are obviously cars—sedans, coupes, convertibles, hatchbacks, and station wagons—are defined as “cars” for the purpose of determining fleet share. Everything else—SUVs, smaller SUVs (crossovers), vans, and pickup trucks—are defined as “light trucks”—even though they may not be treated as such for compliance purposes. In the case of SUVs, in particular, many models may have sales volumes that reside in both the passenger car and light fleets for regulatory purposes, but the dynamic fleet share does not make this distinction. The fleet share model was applied at the same level in the NPRM – namely, at the level of body-style rather than regulatory class. EDF expressed concern that any simulated increase in the light truck share represented consumers shifting from sedans to either 4wheelWD drive crossovers, SUVs or pickup trucks.¹⁶⁰⁶ However, this was not the case. All crossovers are considered light trucks for the purposes of fleet share, even though they may be 2WD crossovers treated as passenger cars for compliance purposes. So, while the number may increase overall for a given scenario, the proportion of crossovers sold as 4WD, rather than 2WD, does not.

EDF was also concerned that the sales implementation in the NPRM, which relied on the absolute average price to determine differences between alternatives, was unduly influenced by fleet share—as differences in the share of light-trucks had the potential to skew differences in average price because light-trucks are generally more expensive than sedans and hatchbacks. The final rule implementation, which starts from an observed average transaction price and evolves the average price in the alternatives based on average regulatory cost, is less vulnerable to this potential distortion. Even if the fleet share model (described in greater detail below) increases the share of light trucks (for example), the inherent price difference between passenger cars and light trucks does not pass through to the average price—only the relative difference in compliance costs associated with the vehicle types. Despite the fact that light trucks have generally higher transaction prices than passenger cars, there is no guarantee that regulatory costs will be higher for light-trucks than for cars (which depend upon the mix of footprints, their distance from the relevant curve, and the technology cost needed to bring each fleet into

¹⁶⁰⁶ EDF, Appendix B, NHTSA-2018-0067-12108, at 40-41 .

compliance). Thus, the average price differences used in the sales calculations are relatively unaffected by the fleet share model.

As in the NPRM, the dynamic fleet share represents two difference equations that independently estimate the share of passenger cars and light trucks, respectively, given average new market attributes (fuel economy, horsepower, and curb weight) for each group and current fuel prices, as well as the prior year's market share and prior year's attributes. The two independently estimated shares are then normalized to ensure that they sum to one. As with the Sales Response model, the DFS utilizes values from one and two years preceding the analysis year when estimating the share of the fleet during the model year being evaluated. For the horsepower, curb weight, and fuel economy values occurring in the model years before the start of analysis, the DFS model uses the observed values from prior model years. After the first model year is evaluated, the DFS model relies on values calculated during analysis by the CAFE model. The DFS model begins by calculating the natural log of the new shares during each model year, independently for each vehicle class, as specified by the following equation:

Equation 5 - Dynamic Fleet Share Equation

$$\ln(\text{Share}_{VC,MY}) = \begin{pmatrix} \beta_C \times (1 - \beta_{Rho}) + \beta_{Rho} \times \ln(\text{Share}_{VC,MY-1}) \\ + \beta_{FP} \times (\ln(\text{Price}_{Gas,MY}) - \beta_{Rho} \times \ln(\text{Price}_{Gas,MY-1})) \\ + \beta_{HP} \times (\ln(\text{HP}_{VC,MY-1}) - \beta_{Rho} \times \ln(\text{HP}_{VC,MY-2})) \\ + \beta_{CW} \times (\ln(\text{CW}_{VC,MY-1}) - \beta_{Rho} \times \ln(\text{CW}_{VC,MY-2})) \\ + \beta_{MPG} \times (\ln(\text{FE}_{VC,MY-1}) - \beta_{Rho} \times \ln(\text{FE}_{VC,MY-2})) \\ + \beta_{Dummy} \times (\ln(0.423453) - \beta_{Rho} \times \ln(0.423453)) \end{pmatrix}$$

Where:

- $\beta_C - \beta_{Dummy}$: set of beta coefficients, as defined by [Table II-52](#)~~Table VI-132~~ below, used for tuning the Dynamic Fleet Share model,
- $\text{Share}_{VC,MY-1}$: the share of the total industry new sales classified as vehicle class VC, in the year immediately preceding model year MY,
- $\text{Price}_{Gas,MY}$: the fuel price of gasoline fuel, in cents per gallon, in model year MY,¹⁶⁰⁷,

¹⁶⁰⁷ As discussed elsewhere in this final rule, model year and calendar year are assumed to be equivalent in the simulation—as they always have been in all prior rulemaking analyses.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- $Price_{Gas,MY-1}$: the fuel price of gasoline fuel, in cents per gallon, in the year immediately preceding model year MY ,
- $HP_{VC,MY-1}$: the average horsepower of all vehicle models belonging to vehicle class VC , in the year immediately preceding model year MY ,
- $HP_{VC,MY-2}$: the average horsepower of all vehicle models belonging to vehicle class VC , in the year preceding model year MY by two years,
- $CW_{VC,MY-1}$: the average curb weight of all vehicle models belonging to vehicle class VC , in the year immediately preceding model year MY ,
- $CW_{VC,MY-2}$: the average curb weight of all vehicle models belonging to vehicle class VC , in the year preceding model year MY by two years,
- $FE_{VC,MY-1}$: the average on-road fuel economy rating of all vehicle models (excluding credits, adjustments, and petroleum equivalency factors) belonging to vehicle class VC , in the year immediately preceding model year MY ,
- $FE_{VC,MY-2}$: the average on-road fuel economy rating of all vehicle models (excluding credits, adjustments, and petroleum equivalency factors) belonging to vehicle class VC , in the year preceding model year MY by two years,
- 0.423453 : a dummy coefficient, and
- $\ln(Share_{VC,MY})$: the natural log of the calculated share of the total industry fleet classified as vehicle class VC , in model year MY .

In the equation above, the beta coefficients, β_C through β_{Dummy} , are provided in the following table. The beta coefficients differ depending on the vehicle class for which the fleet share is being calculated.

Table II-~~52425~~ - DFS Coefficients

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Once the initial car and light truck fleet shares are calculated (as a natural log), obtaining the final shares for a specific vehicle class is simply a matter of taking the exponent of the initial value, and normalizing the result at one (or 100%). This calculation is demonstrated by the following:

Equation 6 - Normalizing individual fleet shares

$$Share_{VC,MY} = \frac{e^{\ln(Share_{VC,MY})}}{e^{\ln(Share_{LDV,MY})} + e^{\ln(Share_{LDT1/2a,MY})}}$$

Where:

- $\ln(Share_{VC,MY})$: the natural log of the calculated share of the total industry fleet classified as vehicle class *VC*, in model year *MY*,
- $\ln(Share_{LDV,MY})$: the natural log of the calculated share of the total industry fleet classified as light duty passenger vehicles (LDV), in model year *MY*,
- $\ln(Share_{LDT1/2a,MY})$: the natural log of the calculated share of the total industry fleet classified as class 1/2a light duty truck (LDT1/2a), in model year *MY*, and
- $Share_{VC,MY}$: the calculated share of the total industry fleet classified as vehicle class *VC*, in model year *MY*.

These shares are applied to the total industry sales derived in the first stage of the sales response. This produces total industry volumes of car and light truck body styles. Individual model sales are then determined from there based on the following sequence: 1) individual manufacturer shares of each body style (either car or light truck) times the total industry sales of that body style, then 2) each vehicle within a manufacturer's volume of that body-style is given the same percentage of sales as appear in the 2017 fleet. This implicitly assumes that consumer preferences for particular styles of vehicles are determined in the aggregate (at the industry level), but that manufacturers' sales shares of those body styles are consistent with MY2017 sales. Within a given body style, a manufacturer's sales shares of individual models are also assumed to be constant over time. We assume that manufacturers are currently pricing individual vehicle models within market segments in a way that maximizes their profit. Without more information about each OEM's true cost of production and operation, fixed and variables costs, and both desired and achievable profit margins on individual vehicle models, we have no reason to assume that strategic shifts within a manufacturer's portfolio will occur in response to standards.

The Global Automakers noted in their comments that the market share of SUVs continues to grow, while conventional passenger car body-styles continue to lose market

share.¹⁶⁰⁸ The agencies are aware of this, and include the DFS model in an attempt to address these market realities. In the 2012 final rule, the agencies projected fleet shares based on the continuation of the baseline standards (MY2012-2016) and a fuel price forecast that was much higher than the realized prices since that time. As a result, that analysis showed passenger car body-styles comprising about 70 percent of the new vehicle market by 2025. The reality, as Global Automakers note, has been quite different.

The coefficients of the DFS model show passenger car styles gaining share with higher fuel prices and losing them when prices are lower. Similarly, as fuel economy increases in light truck models, which offer consumers other desirable attributes beyond fuel economy (ride height or interior volume, for example) their relative share increases. NRDC, in particular, found this counterintuitive.¹⁶⁰⁹ However, this approach does not suggest that consumers *dislike* fuel economy in passenger cars, but merely recognizes the fact that fuel economy has diminishing returns. As the fuel economy of light trucks increases, the tradeoff between passenger car and light truck purchases increasingly involves a consideration of other attributes. Similarly, the coefficients show a relatively stronger preference for power improvements in cars than light trucks because that is an attribute where trucks have outperformed cars, like cars have outperformed trucks for fuel economy.

Rather than estimate new functions to determine relative market shares of cars and light trucks, we applied existing functions from the transportation module of the National Energy Modeling System (NEMS) that was used to produce the 2017 Annual Energy Outlook. The functions above appear in the “tran.f” input file to that version of NEMS, and were embedded (in their entirety) in the CAFE model in the NPRM (and this final rule). NEMS uses the functions to estimate the percent of total light vehicles less 8,500 GVW that are cars/trucks. While NRDC asserted that the agencies must demonstrate the propriety of the fleet share model before relying on its estimates,¹⁶¹⁰ they ignore the fact that, by using the AEO to develop a static fleet in prior rulemakings, the agencies have always relied on NEMS estimates. The primary difference between those analyses and the NPRM (and this final rule), is that prior analyses applied the fleet share that was simulated for the baseline to all regulatory scenarios considered. Based on the fleet share functions in NEMS, NPRM corrected this internal inconsistency found in previous analyses. This approach also enables consistent sensitivity cases—where higher fuel prices produce fleets with more transitional passenger car body styles, for example—and ensures that the starting point (MY2017) evolves in response to both fuel economy improvements and fuel prices in a way that is internally consistent.

The agencies are making one change to the DFS function, which is the level of application. While NEMS intended the fleet shares to be defined by regulatory classes, vehicles are defined much more coarsely in NEMS than in the CAFE model, and manufacturers are not differentiated at all. In order to produce well-behaved fleet share projections with this model, we

¹⁶⁰⁸ Global Automakers, Attachment A, NHTSA-2018-0067-12032, at 13.

¹⁶⁰⁹ NRDC, Attachment 3, NHTSA-2018-0067-11723, at 5..

¹⁶¹⁰ *Id.*

applied the share functions to body-styles rather than regulatory classes. For many years, there was little overlap between nameplates in a manufacturer's passenger car regulatory class and its light truck regulatory class. However, with the recent emergence of smaller FWD SUVs and crossovers, it is increasingly common to have nameplates with model variants in both the passenger car and light truck regulatory classes, and it is also common for there to be only minor differences (like the presence of 4WD or AWD) between versions regulated as cars and versions regulated as light trucks. We have modified the application of the fleet share equations to focus on body-style, rather than regulatory class, in recognition of the increased ambiguity between the regulatory class distinction for popular models like the Honda CR-V and Toyota RAV4, that sell more than 100K units in each regulatory class (typically using the same powertrain configuration). The Nissan Rogue sold more than 400K units in MY2017, and almost exactly half of them were in the light truck (LT) regulatory class. Applying the fleet share at the body-style level preserves the existing regulatory class splits for nameplates that straddle the class definitions. It also serves to minimize the deviation from the observed MY2017 regulatory class shares over time. Had we applied the share equations at the regulatory class level, as some commenters incorrectly claimed the agencies were doing in the proposal, the passenger car regulatory class would have eroded much faster than we've seen in the real world and ceased to resemble the composition of the MY2017 fleet. Our implementation allows the passenger car (PC) regulatory class to continue evolving toward crossover-type cars, if that is what economic and policy conditions favor.

Table II-53426 - Regulatory Class Shares Under CAFE¹⁶¹¹

¹⁶¹¹ The "passenger car" fleet for CAFE represents the combination of both imported passenger cars (IC) and domestic cars (DC). While Table II-53Table I-40 illustrates shares for the CAFE program, resulting shares under the tailpipe CO₂ emissions standards are comparable.

Table II-53~~Table VI-133~~ shows the regulatory class shares under the baseline (augural standards), proposal (0 percent increase in stringency), and final rule (1.5 percent increase in stringency) between 2017 and 2030. The shares move relatively little between the classes in the baseline, with larger (but still small) deviations occurring in the least stringent alternative (0 percent increase) and the final rule. As the sensitivity cases show, the changes in shares (both over time and between regulatory classes) respond to the fuel price case, but remain internally consistent due to the inclusion of the DFS.

Some commenters encouraged the agencies to consider vehicle attributes beyond price and fuel economy when estimating a sales response to fuel economy/CO₂ standards, and suggested that a more detailed representation of the new vehicle market would allow the agencies to simulate strategic mix shifting responses from manufacturers and diverse attribute preferences among consumers. Doing so would have required a discrete choice model (at some level), and we describe below the reasons why we have not chosen to employ that approach in this final rule.

(c) Using vehicle choice models in rulemaking analysis

Some commenters argued that the NPRM's statistical model used to estimate changes in sales between alternatives was too highly aggregated and missed consumers' valuation of other vehicle attributes. CARB, Cities and States, and EDF all made some version of the argument that the sales model in the NPRM operated at too high a level of aggregation to estimate the real sales response, which primarily occurs at the model level where consumers are making decisions based on the comprehensive set of attributes and body styles available in the market. They also argued that a model must operate at the same level, such as a discrete choice model, in order to capture consumer response accurately. EPA's Science Advisory Board, Bento, Toyota, Automobile Alliance, RFF, and Bunch (writing on behalf of CARB) insisted that the best approach to estimating the change in sales across alternatives is to use a discrete choice model and embed it in the simulation.

Other commenters expressed different views on the importance of a consumer choice model. For example, while the Aluminum Association supported a consumer choice model, they suggested that total new vehicle sales may not change due to increases in price, but rather the attributes of new vehicles would shift, as consumers would likely shift their purchases toward lower content vehicles (in terms of safety, luxury, or other option content) when faced with generally higher prices. Other commenters, including UCS and CBD, strongly encouraged the agencies to avoid using consumer choice models; commenters asserted that consumer choice models have historically lacked reliability and predictive power.¹⁶¹²

In general, these various comments present the agencies with considerably different suggestions on how to address these issues, and certain suggestions are in direct opposition to

¹⁶¹² UCS, Technical Appendix, NHTSA-2018-0067-12039 at 50.

each other. That is, while some commenters argue that only micro-level consumer responses are relevant to the analysis, and that a consumer choice model is required to estimate these responses, others argue that it is inappropriate to use a discrete choice model—the method by which those responses are econometrically estimated—in a regulatory analysis. Adding to the confusion, some of the same commenters who argued against a consumer choice model,¹⁶¹³ also argued that it was necessary for the analysis to account for the influence of other vehicle attributes in purchasing decisions, which would require incorporating a discrete choice model.

CARB argued that “accurately capturing the relative impact of sales shifts versus no-buy decisions would require a more detailed consumer choice model, as recommended by the CAFE Model peer reviewers. The current new vehicle sales model has no way of capturing these types of effects.”¹⁶¹⁴

David Bunch, writing for CARB, said, “In fact, in previous versions of the CAFE model there were no attempts to directly simulate consumer response from *within* the CAFE model at all. Instead, NHTSA relied on fixed projections of future vehicle market behavior from multiple sources for the purpose of performing the required economic cost and benefit calculations. While this might possibly be less than ideal, this approach is only a problem if, in the real world, there [are] notable *differences* in future market behavior [that] occur under different regulation scenarios, and, moreover, that these differences would be large enough to compromise the validity of the net benefit comparisons.” Bunch essentially argues that the old approach, asserting that standards can have no impact on sales, even at the individual model level, is more appropriate than trying to capture the general idea that when all new vehicles get more expensive, consumers are likely to buy fewer of them, all else being equal. The agencies disagree with that perspective.

There are a number of practical challenges to using estimates of consumer attribute preferences to simulate market responses. Discrete choice models typically rely on fixed effects (or alternative-specific constant terms) to account for the unobserved characteristics of a given model that influence purchasing decisions, such as styling,¹⁶¹⁵ but are not captured by independent variables that represent specific vehicle attributes (horsepower, interior volume, or safety rating, for example). Ideally, these constant terms would contribute relatively little to the fit and performance of the model, assuming that the most salient characteristics are accounted for explicitly. In practice, this is seldom the case. While the fixed effects at the model level are statistically sound estimates of consumer preferences for the unobserved vehicle characteristics of the individual models, the estimates are inherently historical—based on observed versions of the specific vehicle models to which they belong. However, once the simulation starts, and new technologies are added to each manufacturer’s product portfolio over successive generations, it is no longer obvious that those constant terms would still be valid in the context of those changes.

¹⁶¹³ For example, *see* EDF, NRDC, RFF, NCAT, and CBD comments.

¹⁶¹⁴ CARB, Detailed Comments, NHTSA-2018-0067-11873, at 192.

¹⁶¹⁵ Aesthetics such as styling are difficult, if not impossible, to define in a manner that allows meaningful comparison between choices.

Another complication is that discrete choice models are highly dependent on their inputs and are unable to account for future market changes. For example, the Draft TAR relied on a MY 2014 market (for EPA's analysis) and a MY 2015 market (for NHTSA's analysis), while the NPRM used a MY 2016 fleet, and this final rule has updated the market characterization to a MY 2017 fleet. A discrete choice model estimated on any of those model years would probably produce different fixed effects estimates for each model variant in the fleet. Even assuming that no new variants of a given model are offered over time, new nameplates emerge as others are retired—and for those new nameplates and all of their model variants, no constant terms would exist. They would have to be imputed (either from comparable vehicles in the market, some combination of their attributes, or both). Some studies have attempted to estimate fixed effects for a single new entrant to the market,¹⁶¹⁶ but none have attempted to do so at the scale required to migrate a discrete choice model fit on an earlier model year to a newer model year for simulation.

Error! Reference source not found. shows the cumulative percentage of nameplates in the 2017 new vehicle market by year of introduction. About ten percent of nameplates in 2017 have been around since the 1970s, but another ten percent have only existed since about 2010. This fact illustrates the likely necessity of constructing vehicle model fixed effects for the inevitable new entrants between the estimating fleet and the rulemaking fleet. But it also suggests another challenge. New model entrants are driven by the dynamics of the market, where some vehicle models succeed and others fail, but a simulated market with a discrete choice model can only simulate failure—where consumer demand for specific nameplates erode to the point that the nameplate volumes trend toward zero. It has no mechanism to generate new nameplates to replace those nameplates whose sales it estimates will erode beyond some minimal practical level of production.

Consumer choice models are typically fit on a single year of data (a cross-section of vehicles and buyers), but this approach misses relevant trends that build over time, such as rising GDP or shifting consumer sentiment toward emerging technologies. If such a model is used to estimate total sales, but lacks trends in GDP growth or employment, etc., it will have the wrong set (likely a smaller set) of new vehicle buyers and exaggerate price responses and attribute preferences. Consumer preferences change over time in response to any number of factors—given manufacturers' recent investments in electric powertrains, they are counting on this fact. But a choice model estimated on observed consumer preferences for EVs—or other vehicle attributes with comparatively little experience in the market—would necessarily disadvantage a technology that is currently (or only recently) unpopular, but gaining popularity. While these are problems that may not matter in the estimation process, where a researcher is attempting to measure revealed consumer preference for given attributes at a single point in time, they become material once that model is integrated into the simulation and dynamically carried forward for three decades. The agencies note that models that examine aggregate trends, such as the one

¹⁶¹⁶ Berry, Steven, James Levinsohn, and Ariel Pakes (2004). Differentiated products demand systems from a combination of micro and macro data: The new car market. *Journal of Political Economy* 112(1): 68-105.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

utilized in this analysis, are able to side-step this issue by not placing a value on unique vehicle attributes.

Figure II-2657 - Nameplate Introduction and Attrition

The agencies' compliance simulation model estimates the additional cost of technology required to achieve compliance, or to satisfy market demand for additional fuel economy. While it necessarily calculates these costs on a per-vehicle basis, estimating the cost of additional technologies as they are applied to each specific model in order to bring an entire fleet into compliance, it is agnostic about how these costs are distributed to buyers. Manufacturers have strategic, complex pricing models that rely on extensive market research and reflect each company's strategic interests in each segment. Automobile companies attempt to maximize profit from the sale of their vehicles, rather than solely focusing on minimizing the cost of compliance, as we simulate. Lacking reliable data for each manufacturer on production costs and profit margins for each vehicle model in their portfolios, the most reasonable course of action is to simulate compliance as if OEMs are attempting to minimize costs, and, worth noting, this approach is also the one NHTSA takes in its rulemakings related to the FMVSS. However, it is obvious that some market segments and individual models are much less elastic than

others.¹⁶¹⁷ As reflected in the prices of those models, consumers are able to bear a greater share of the total cost of compliance before negatively affecting sales and manufacturer profits.

Several commenters (CARB, CBD, IPI, and Bento et al.) suggested that the agencies should employ a pricing model that allows manufacturers to vary prices in response to heterogeneous consumer preferences and different levels of willingness to pay for fuel economy, and other attributes, in the new vehicle market. Fundamentally, this would require the agencies to model strategic pricing for each manufacturer individually—no single pricing model would be appropriate for every manufacturer. Bento et al. stated that the agencies should simulate the market by allowing manufacturers to dynamically adjust vehicle prices to ensure compliance with the standards.¹⁶¹⁸ There is no reasonable expectation that the agencies could embed and utilize each manufacturer’s pricing strategy, as this is an essential feature of competitive corporate behavior and that automakers closely hold pricing strategy information and the agencies have insufficient information to model manufacturer pricing strategies. Furthermore, models in the academic literature that commenters have suggested are superior because they allow prices to adjust, merely demonstrate that the mechanics of those adjustments work; they do not imply that the resulting prices are reasonable or realistic. Given the burden to estimate each manufacturer’s standard under the attribute-based system, where the mix of vehicles sold defines not only the achieved fuel economy of each fleet but also the standard to which it is compared, the agencies are understandably reluctant to implement models that might shift a manufacturer’s mix of vehicles sold within a market segment.

Bunch suggested the agencies use a joint model of household vehicle holdings and sales that encompasses decisions to purchase new vehicles, retain existing ones, or reduce or augment current holdings of vehicles of all types and vintages in each period. Manufacturers would modify either new vehicle content, prices, or both to produce a supply of new vehicles that allowed them each to comply with standards. And the households and manufacturers would iteratively interact until the market reached equilibrium. The model described by Bunch would face many of the same issues outlined above. There are significant econometric challenges associated with estimating a household’s decision to buy a new vehicle instead of a used vehicle (of some vintage), or to maintain its current set. And integrating such a model would require the agencies to simulate the dynamics of the used vehicle market—hundreds of unique nameplates for each of dozens of vintages—in order to provide the correct choice set in each simulated year. Such a model is beyond the scope of the current analysis.

While the agencies believe that these challenges provide a reasonable basis for not employing a discrete choice model in today’s final rule analysis, the agencies also believe they are not insurmountable, and that some suitable variant of such models may yet be developed for use in future fuel economy and CO₂ emissions rulemakings. The agencies have not abandoned the idea and plan to continue experimenting with econometric specifications that address

¹⁶¹⁷ See, for example, Kleit, A.N. (2004), Impacts of Long-Range Increases in the Fuel Economy (CAFE) Standard. *Economic Inquiry*, 42: 279-294. doi:10.1093/ei/cbh060.

¹⁶¹⁸ NHTSA-2018-0067-12326 at 10.

heterogeneous consumer preferences in the new vehicle market as they further refine the analytical tools used for regulatory analysis.

Operating at the level of individual auto and light truck model variants—the same level at which compliance is, necessarily, simulated—may not be tractable for rulemaking analyses. However, market shares for brands and manufacturers within market segments are more stable over time—even if the volumes of segments across the industry fluctuate. In the 2012 final rule, the agencies’ analysis showed a new vehicle market where the share of passenger car body styles—sedans, coupes, hatchbacks—reached almost 70 percent of the new vehicle market by 2025, while light trucks, including many crossovers, accounted for the remaining 30 percent. Those results were consistent with the assumptions made in 2012, but the combination of low fuel prices and decreasing differences in fuel consumption between body styles has instead reduced the market share of those body styles significantly (only 40% in the MY 2017 fleet), and, thus eroded the value of the 2012 analysis to inform current decisions. Including a choice model that operated on existing market shares, albeit at a higher level of aggregation than specific nameplates, such as brand/segment/powertrain, may be able to improve internal consistency with the interaction of assumptions about fuel prices and regulatory alternatives. The agencies will continue to engage with the academic community and other stakeholders to ensure that future work on this question improves our analysis of regulatory alternatives.

(3) *Scrappage*

(a) *The Impacts of New Vehicle Fuel Economy Standards on Fleet Turnover*

Economic literature and theory indicate that the retirement (or scrappage) rates of existing vehicles slows when new vehicle fuel economy standards increase and cause new vehicle price increases. Slower retirement rates result in an older distribution of the on-road fleet. Today’s on-road fleet is the oldest it has ever been, approaching an average of 12 years old.¹⁶¹⁹ Since older vehicles are, on average, less safe and less fuel efficient, modeling this reduction in the scrappage rates of existing vehicles has important implications. As mentioned in the sales section above, past quantitative analyses of CO₂ and CAFE standards excluded the scrappage effect (though the agencies discussed the scrappage effect qualitatively), which could have resulted in an overestimate of the benefits of increasing standards.

For the NPRM, the agencies chose for the first time to model the change in existing vehicle retirement rates across regulatory alternatives. The agencies used a logistic function to estimate the instantaneous scrappage rate for vehicles of different body styles and model year vintages using registration data from Polk, the estimated durability of specific model year

¹⁶¹⁹ Bureau of Transportation Statistics (BTS). “Average Age of Automobiles and Trucks in Operation in the United States.” Available at <https://www.bts.gov/content/average-age-automobiles-and-trucks-operation-united-states>.

vintages, the prices of new vehicles, a measure of the cost of travel for the model year cohort versus new vehicles in any given calendar year, and other cyclical macroeconomic indicators.¹⁶²⁰

The agencies received many comments about the NPRM's scrappage model. While some commenters objected to the inclusion of a scrappage model, most commenters supported the inclusion of a dynamic scrappage model as an improvement in the agencies' analysis; these comments are discussed in Section I.A.1.a)(1)(a)(ii). Other commenters raised concerns about the specific scrappage models used in the NPRM analysis; these are discussed in Section I.A.1.a)(1)(b). Specifically, commenters raised concerns about overfitting in the models, the identification strategy, the modeling of new and used vehicle fuel economy in general, the exclusion of certain variables, about how the agencies captured macroeconomic effects, and about the lack of integration with the sales model.

The agencies contemplated all of the comments and suggestions made by commenters and, in response, have made several changes to final rule's model. First, we changed the time-series strategy used in the model, as discussed in Section I.A.1.a)(1)(c)(iii)(a). This change allows the agencies to simplify the models significantly, addressing commenters' concerns about potential overfitting of the model and difficulty of interpreting individual coefficient values (discussed in Section I.A.1.a)(1)(b)(i)). Second, the agencies changed the modeling of the durability effect as discussed in Section I.A.1.a)(1)(c)(iii)(c); this change reduces the reliance on the decay function and has the added benefit of addressing concerns about overfitting and out-of-sample projections discussed in Section I.A.1.a)(1)(b)(i). Third, a portion of anticipated fuel savings from increased fuel economy are netted from new vehicle prices—meaning consumers are now assumed to value fuel economy at the time of purchase to a certain extent—as discussed in Section I.A.1.a)(1)(c)(iii)(d). This change is in response to comments discussed in Section I.A.1.a)(1)(b)(ii) and addresses inconsistent treatment of consumer valuation within the NPRM's analysis. Finally, we consider the inclusion of additional or alternative variables in the scrappage model in response to comments discussed in Section I.A.1.a)(1)(b)(iii). After extensive testing, the agencies concluded that these additional variables do not improve the model fits or would introduce autocorrelation in the error structures (see Sections I.A.1.a)(1)(c)(iii)(e) and I.A.1.a)(1)(c)(iii)(f) for further discussion). As such, the agencies rejected the additional terms suggested by commenters. Input from commenters was used to simplify the scrappage model, make it more consistent with modeling of new vehicle prices elsewhere in the analysis, and improve its predictions for the instantaneous scrappage rates of vehicles beyond age 20.

(i) Basis for 'The Gruenspecht Effect'

Gruenspecht (1981) and (1982) recognized that since fuel economy standards affect only new vehicles, any increase in price (net of the portion of reduced fuel savings valued by consumers) will increase the expected life of used vehicles and reduce the number of new vehicles entering the fleet. The effects of differentiated regulation in the context of fuel

¹⁶²⁰ For a more detailed explanation of the NPRM model, see PRIA Chapter 8.10.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

economy is often deemed the *Gruenspecht Effect*.¹⁶²¹ Jacobsen and van Benthem (2015) first quantified the Gruenspecht Effect, or the share of new vehicle fuel savings lost to the used vehicle fleet due to delayed scrappage, to be between 13 and 16 percent.¹⁶²²

As discussed in the write up of the sales model, fuel economy standards increase the cost of acquiring new vehicles, but also improve the quality of those vehicles by increasing their fuel economy. The CAFE analysis assumes that consumers value 30 months of fuel savings, so that the quality-adjusted change in new vehicle prices is the increase in regulatory costs less 30 months of fuel savings. As long as the quality-adjusted price is positive,¹⁶²³ it becomes more expensive for manufacturers to produce vehicles and, as a result, prices of new vehicles increase. From a supply and demand perspective, this equates to the supply curve for new vehicles moving inwards or to the left and a corresponding increase in the equilibrium price and decrease in the equilibrium quantity of new vehicles purchased.

New and used vehicles are substitutes. When the price of a good's substitute increases, the demand curve for that good shifts upwards and the equilibrium price and quantity supplied also increases. Thus, increasing the quality-adjusted price of new vehicles will result in an increase in equilibrium price and quantity of used vehicles. Since, by definition, used vehicles are not being "produced" but rather "supplied" from the existing fleet, the increase in quantity must come via a reduction in their scrappage rates. Practically, when new vehicles become more expensive, demand for used vehicles increases (and they become more expensive). Because used vehicles are more valuable in such circumstances, they are scrapped at a lower rate, and just as rising new vehicle prices push marginal prospective buyers into the used vehicle market, rising used vehicle prices force marginal prospective buyers of used vehicles to acquire older vehicles or vehicles with fewer desired attributes.

(ii) Commenter Response to the Inclusion of the Gruenspecht Effect

(a) Many Commenters Support the Inclusion of the Effect

Academic researchers and automakers widely agree with the existence and direction of the Gruenspecht Effect. For example, RFF commented, "There's good evidence supporting the scrappage effect."¹⁶²⁴ The Auto Alliance stated that the agencies "made significant strides toward improving their modeling of consumer behavior by adding new modules to estimate new vehicle sales and in-use vehicle scrappage in response to changes to new vehicle prices."¹⁶²⁵

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

FCA agreed “that an outcome of the current aural stringency of the CAFE/[CO₂] emission regulations may be a decreasing trend in vehicle scrappage rates as consumers delay purchases [...] forc[ing] consumers to hold their current vehicles for additional time.”¹⁶²⁶

Other commenters agreed with the existence of the effect, but took issue with the implications of the combination of the sales and scrappage models. Mark Jacobsen stated “while we agree that the scrappage effects we study will mitigate changes in the used fleet, we do not believe they could be strong enough to reverse completely the direction of change in the used fleet.”¹⁶²⁷ Jacobsen’s contention was echoed by many commenters; the main point was that they believed that the prices of both new *and* used vehicles should be less expensive in the NPRM’s preferred alternative than the aural standards, and that this should, if anything, result in a larger fleet in the NPRM’s preferred alternative. This issue is further discussed in Section (b)(iv) with other comments about integrating the sales and scrappage models and the incremental fleet size across alternatives. Here it is important to note that this concern does not suggest that a scrappage model *should not exist*, but takes issue with the *specific modeling* of scrappage and/or sales implemented in the NPRM analysis.

(b) Some Commenters Worry about the Shift in Agency Perspective

Some commenters argued that the agencies modeling of sales and scrappage in the NPRM analysis contradicted previous positions that these effects were too uncertain to model. For example, the Center for Biological Diversity (CBD) commented:

In the 2012 rulemaking for fuel economy and [CO₂] standards, both NHTSA and EPA stated that analysis of the standards’ impact on new vehicles sales and on the “scrappage” of used vehicles was too uncertain to be used in the rulemaking. The agencies reiterated this position in their 2016 technical assessment of the standards.¹⁶²⁸

They further stated:

The agencies have not provided a meaningful rationale or justification for the change in position regarding their ability to present quantified estimates of the impact of the standards on new vehicle sales and the scrappage of used vehicles.¹⁶²⁹

To respond to these comments, it is useful to look at the reasons the agencies gave for not considering fleet turnover effects on pages 845-46 of the 2012 rulemaking:

If the value of fuel savings resulting from improved fuel efficiency to the typical potential buyer of a new vehicle outweighs the average increase in new models’ prices, sales of

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

new vehicles will rise, while scrappage rates of used vehicles will increase slightly. This will cause the “turnover” of the vehicle fleet—that is, the retirement of used vehicles and their replacement by new models—to accelerate slightly, thus accentuating the anticipated effect of the rule on fleet-wide fuel consumption and CO₂ emissions. However, if potential buyers value future fuel savings resulting from the increased fuel efficiency of new models at less than the increase in their average selling price, sales of new vehicles will decline, as will the rate at which used vehicles are retired from service. This effect will slow the replacement of used vehicles by new models, and thus partly offset the anticipated effects of the final rules on fuel use and emissions.

*Because the agencies are uncertain about how the value of projected fuel savings from the final rules to potential buyers will compare to their estimates of increases in new vehicle prices, we have not attempted to estimate explicitly the effects of the rule on scrappage of older vehicles and the turnover of the vehicle fleet.*¹⁶³⁰

The agencies’ reason for not modeling the fleet turnover effects in prior rulemakings was not uncertainty about the direction or impact of vehicle prices on sales or scrappage rates, but rather uncertainty about how consumers value fuel savings. The agencies now have sufficient knowledge regarding the amount of fuel savings consumers are assumed to value at the time they purchase new vehicles and make these assumptions in the technology application simulation. With this assumption, it becomes possible to model the fleet turnover effects, including the scrappage effect.

(c) Some Commenters Think the Effects
Are Uncertain

Other commenters argue that the sales and scrappage effects are too uncertain to include in a rulemaking analysis. For example, CBD argued that “the models are attempting to evaluate the small and uncertain effects of changes in vehicle standards on certain dynamics—vehicle sales, scrappage rates, and vehicle usage—which are largely determined by much stronger forces, such as the state of the economy.”¹⁶³¹

The agencies agree that there is uncertainty around the magnitude of the sales and scrappage response, but do not agree that sign of either effect is uncertain. Importantly, excluding modeling of the sales and scrappage effects would only make sense if there was a legitimate existential concern—the sales and scrappage effects are founded in very basic economic theory, as noted above, in Section I.A.1.a)(1)(a)(i). Furthermore, the agencies believe that assessing the magnitudes of the sales and scrappage effects is a tractable task for researchers and sufficient data exists to quantify these effects. Thus, excluding these effects would be a serious omission that limits accurate accounting of the costs and benefits of fuel economy standards. Other stakeholders commented that the NPRM analysis did not thoroughly consider

¹⁶³⁰ 77 Fed. Reg. 62,623, 63,112-13 (emphasis added).

¹⁶³¹ CBD, Appendix A, NHTSA-2018-0067-12000, at 177.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

the uncertainty around the magnitudes of the sales and scrappage responses. These comments and the agencies response is discussed in Section I.A.1.a)(1)(b)(i), below. The agencies believe it is better to consider a range of the scrappage and sales response to address concerns about uncertainty, and that excluding them would be inappropriate.¹⁶³² The agencies did just that with the proposal through sensitivity analyses—including seeking comment and having the scrappage modeling peer reviewed—and continue to do so for the final rule.

(b) *Summary of Notice, Request for Comments, and the Agencies' Response*

The comments related to the scrappage model are summarized here into five major categories: overfitting and identification strategies, modeling fuel economy and new vehicle prices, consideration of other additional variables, integration with sales or VMT, and evaluations of associated costs and benefits due to changes in scrappage rates within the CAFE model. Specific modeling decisions the agencies have made or considered in response to the public comments summarized in this section are discussed in Sections I.A.1.a)(1)(c)(ii)(d) and I.A.1.a)(1)(c)(iii).

(i) Overfitting and Identification Strategy

Several commenters argued that the NPRM scrappage model did not have a clear identification strategy, or that the model *over-fit* the data. These commenters suggest that the NPRM model may not capture a causal relationship, but picks up other correlation or noise within the data. This section outlines the specific claims made by commenters.

(a) Overfitting and the Use of Lagged and Interactions Terms

Several commenters argued that the results presented in the NPRM could be driven by the specific structure of the price effect used in the scrappage models that were implemented into the CAFE Model. IPI, California States et. al., CARB, and other commenters suggested that the NPRM model is over-fit. CARB outlined its argument that the agencies overfit the data in the following passage:

[T]he model appears to be significantly overfit and to suffer from multicollinearity. An overfit model means that the model is able to precisely replicate past trends, but only through the use of too many variables. An overfit model fits the data too well, fitting the noise or errors in the data in addition to the underlying relationships between the variables of interest. Because an overfit model also fits the noise and errors of the data, the out-of-sample predictions are unreliable. Comments from Jeremy Michalek and Katie

¹⁶³² See, e.g. *Ctr. for Biological Diversity v. Nat'l Highway Traffic Safety Admin.*, 538 F.3d 1172, 1203 (9th Cir. 2008), (finding that NHTSA inappropriately assigned no value to reducing carbon emissions when the value for doing so was “certainly not zero.”).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Whitefoot suggest that choice of specification of the scrappage model could result in substantially different predictions, and that the agencies should make only those claims that are robust to reasonable variations in the model specifications.¹⁶³³

The agencies agree that it is important that the scrappage model results are robust across those specifications that meet a set of econometric criteria (these criteria are discussed further in Section I.A.1.a)(1)(c)(iii)). However, the agencies acknowledge that the NPRM could have provided further evidence that the specification did not drive the results. In the analysis for the final rule the agencies have presented more than one specification of the price effect as evidence that the specification chosen here does not drive the results of the analysis. Further, claims that the specification of the scrappage response in the NPRM is inconsistent with economic theory are false.

Theoretically, changes in average new prices may have longer-term trends that can be picked up by including lagged terms, and/or be non-linear with age, so that vehicles of different ages have different elasticities of scrappage (relative to changes in average new vehicle prices). Further, sometimes the effect of one independent variable on the dependent variable depends on the magnitude of another independent variable—this is called an interaction effect. Regression analysis can capture these interaction effects by defining a new variable using some combination of independent variables.¹⁶³⁴ It is necessary to retain such interaction terms when doing so.¹⁶³⁵ For example, it is not obvious that the elasticities of scrappage rates to changes in new vehicle prices should be constant for all vehicle ages, or put another way, the older a vehicle is, the higher likelihood the vehicle will be scrapped instead of being retained or resold.

Michalek and Whitefoot, Honda, and other commenters, argued that the fact that some of the interaction terms were not statistically significant was evidence that the response measured is uncertain. CBD in particular claimed that the “scrappage model is poorly constructed, and its results are not statistically significant.”

In response to such comments, it is important to note that when interaction terms are included, the significance of the overall effect of a variable should be tested by performing a restricted F-test, which simultaneously tests that all coefficients of the variable of interest are jointly indistinguishable from zero. The insignificance of one term of the interaction does not imply that the effect is indistinguishable from zero.¹⁶³⁶

Commenters also noted the lagged terms and age interactions make the new vehicle price effect difficult to interpret. IPI argued that “[t]he inclusion of interaction variables make it very difficult to evaluate the results of the regression for an individual variable of interest.” Michalek and Whitefoot suggested “using a Monte Carlo analysis to understand the distribution of

¹⁶³⁴ Davis, J. B., *Statistics using SAS enterprise guide*. Cary, NC: SAS Institute, pp. 411-415 (2012).

¹⁶³⁵ As explained in more detail in Section I.A.1.a)(1)(a)(ii)(a) ~~I(ii)(a)~~, below, the agencies perform several sensitivity analyses to ensure the model captures the correct impact of interactive effects.

¹⁶³⁶ Davis, J. B., *Statistics using SAS enterprise guide*. Cary, NC: SAS Institute, pp. 411-415 (2012).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

scrapage outcomes implied by uncertainty of the value of the coefficients in the model regression and reporting 95% confidence intervals.”

We agree that the inclusion of lags and age interactions of new vehicle prices can make interpreting the sign and magnitude of the price effect difficult. It also makes it difficult to use the confidence intervals on the coefficients as a way to capture uncertainty, since the interaction variables are jointly estimated. Thus, for the NPRM analysis, we could not independently sample each coefficient from the confidence intervals and perform a Monte Carlo analysis.

While the agencies think that the inclusion of lags and interaction terms is theoretically plausible, in response to commenter and peer reviewer concerns about overfitting and the difficulty of interpreting coefficients, the agencies reconsidered the time series approach. The agencies found that new vehicle prices are integrated to order one and that the dependent variable is stationary (as discussed in Section I.A.1.a)(1)(c)(iii)(a)). It is therefore sufficient to fit the first difference of new vehicle prices within the models. Thus, the agencies have simplified the central model of the response of scrapage rates to changes in new vehicle prices to exclude lags of the effect. The agencies further simplified the central scrapage models to exclude interaction of new vehicle prices and vehicle age; this allows the agencies to take the 95 percent confidence intervals as a low and high range for the magnitude of the price effect for the sensitivity analysis. The agencies also include a sensitivity analysis which includes interaction terms between new vehicle price and vehicle age to allow the elasticity of scrapage to changes in new vehicle price to vary by vehicle age.

Commenters also noted that the model did not perform well for vehicles beyond age 20. The agencies noted in the PRIA that the Polk dataset for older vehicles was limited and likely led to the inability to estimate the scrapage rates for older ages.¹⁶³⁷

The final rule dataset includes almost 30 percent more data for vehicles fifteen years or older than the NPRM, which improves estimates of the scrapage rate of vehicles aged 20 to 30 (see [Table II-54](#)~~Table VI-134~~). The agencies are still unable to capture the scrapage trends for vehicles over 30, as the dataset is still limited for the oldest ages of vehicles, and still rely on the decay function used in the NPRM for vehicles over the age of 30. The limited data explains the inability to predict the scrapage rates for older vehicles. However, including model year fixed effects and including the share of the initial cohort remaining does improve predictions of the final share remaining in the final rule models. These changes are discussed in Section (c)(i)(c).

(b) Reduced Form and Endogenous
Prices

California States et. al., CARB, EDF, IPI and academic commenters expressed concerns that the NPRM analysis fit a reduced form of the scrapage model, rather than a structural model. In other words, instead of explicitly modeling new and used vehicle prices in equilibrium under different regulatory alternatives and applying a measurement of the elasticity of scrapage

¹⁶³⁷ FR, Vol 83, No. 165, August 24, 2018, p.43097.

to the resulting *used* vehicle prices, the agencies modeled the elasticity of scrappage from changes to *new* vehicle prices. For example, California States et. al., argued that the model “does not link the new and used vehicle markets as required by economic theory, nor does it attempt to measure used vehicle prices, which form the basis of scrappage theory.”

While the agencies recognize that there are certain advantages to a structural model, they disagree that the sales of new and used vehicles must be modeled simultaneously. The agencies do link the new and used car markets by including new vehicle prices as an independent variable in scrappage regression equation. However, it would be inappropriate to include used vehicle prices in this equation due to endogeneity concerns. A change in used vehicle prices may change scrappage rates, but also an exogenous shock to scrappage rates may cause used car prices to vary.

Furthermore, the agencies are unaware of a viable structural model for the scrappage effect. The agencies performed an extensive review of economic of literature, both before creating the scrappage model for the proposal and revising it for the final rule, but were unable to find such a model or any insights on how to construct one. The agencies note that commenters did not suggest a structural model that the agencies should use or give any indication of whether such a model exists.

In order to understand why such a model is difficult to construct, it is important to understand what a structural model of the sales and scrappage responses would entail. A hypothetical structural model for the new vehicle market can be represented by the following simultaneous demand and supply equations:

$$D_{New} = \beta_0 + \beta_1 * P_{New} + \beta_2 * P_{Used} + \beta_3 * P_{Transit} + \beta_4 * Income + \beta_5 * Households$$

$$S_{New} = \beta_6 + \beta_7 * P_{New} + \beta_8 * Production\ Cost_{New}$$

The demand equation for new vehicles in a given year is determined by the annual price of owning and operating new vehicles, the annual price of owning and operating used vehicles, the annual price of other substitutes, average household income, and the number of households. The supply equation is made up of the average price of new vehicles and the average cost to produce them.

As noted in the sales model write up, reducing required fuel economy stringency reduces the cost of producing new vehicles, and shifts the supply curve to the right. This results in an increase in the quantity supplied of new vehicles.

The structural model for the used vehicle market can be represented by the following simultaneous demand and supply equations:

$$D_{Used} = \gamma_0 + \gamma_1 * P_{Used} + \gamma_2 * P_{New} + \gamma_3 * P_{Transit} + \gamma_4 * Income + \gamma_5 * Households$$

$$S_{Used} = \gamma_6 + \gamma_7 * P_{Used} + \gamma_8 * Maint\ Repair_{Used} + \gamma_9 * Scrap\ Value_{Used}$$

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The aggregate demand equation for used vehicles is determined by the price of owning and operating used vehicles, the price of owning and operating new vehicles, the price of other transit substitutes, average income, and the number of households. The supply curve equation for used vehicles is determined by the price of used vehicles, the cost to repair and maintain them in service, and the opportunity cost of the scrappage value of doing so. Relaxing new vehicle standards reduces new vehicle prices and shifts the demand curve for used vehicles downward, which reduces demand for used vehicles and the equilibrium price and quantity of used vehicles, and increases the annual scrappage rate.

Modeling the structural equations would require that the agencies predict new and used vehicle prices in equilibrium, allowing prices of new and used vehicles be determined simultaneously from estimates of the supply and demand curves for each market. As CARB stated in the following comment, new and used vehicle prices are endogenous—the equilibrium prices of each good are simultaneous:

Because both scrappage rates and new vehicle prices may influence one another, the Agencies would need to utilize different statistical techniques to credibly identify the impact of new vehicle prices on scrappage rates. For example, the Agencies would need to identify an instrumental variable that impacts new vehicle price but that does not impact the scrappage rate. Models that suffer from endogeneity problems will have biased estimates. In other words, the estimates from these models cannot be used to inform policy, because they do not actually tell us how new vehicle prices impact scrappage.

CARB suggested a way to correct for endogeneity: using an instrumental variable in a two-stage least squares methodology where the instrumental variable is correlated with new vehicle prices, but not scrappage rates.¹⁶³⁸ The agencies could also address the potential for endogeneity in two steps: first, they could model the impacts of exogenous changes in new vehicle prices on used vehicle prices, and second, they could model the impacts of exogenous changes in used prices on scrappage rates. Implementing the first step would require using an instrumental variable to isolate exogenous shifts to the new vehicle supply curve, and then using the predicted values of new vehicle prices to model changes in prices for used vehicles of all ages. Because prices and scrappage rates are jointly determined in the market for used vehicles, predicting the elasticity of scrappage with respect to price variation also requires isolating exogenous changes in used vehicle price via the use of an instrumental variable.

There is one literature example that approaches the structural model that some commenters would like the agencies to implement. Jacobsen and van Benthem¹⁶³⁹ developed a structural model that simultaneously solves for prices that clear new and used vehicle supplies, and then applies an elasticity of scrappage measure that corrects for potential endogeneity of used vehicle values and scrappage rates using an instrumental variable methodology.

¹⁶³⁸ CARB, Detailed Comments, NHTSA-2018-0067-11873, at 244.

¹⁶³⁹ M. Jacobsen and A. van Benthem, “Vehicle Scrappage and Gasoline Policy,” *American Economic Review*, Vol. 105, pp. pp. 1312-38 (2015).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Specifically, they use changes in fuel prices as an instrumental variable; changes in fuel prices shift the demand for different vehicle models, but not the cost of supplying them. This should capture exogenous changes in value, so that an exogenous measure of the scrappage elasticity can be isolated in the second stage of the two-staged least squares method.

While Jacobsen and van Benthem are able to correct for potential endogeneity between used vehicle values and their scrappage rates, their structural model to set new and used vehicle values simultaneously makes some presumptions that the agencies are not comfortable making. First, they calibrate their constant elasticity of substitution (CES) utility function using 1999 data from GM's internal model. This type of model would estimate elasticities of specific vehicle models and require a pricing strategy other than allotting all additional technology costs to the vehicle models to which they are applied. The agencies have avoided a pricing strategy for the reasons cited in the sales model write up. Second, by relying on GM's internal model, Jacobsen and van Benthem used elasticities calculated using only 1999 data of the GM fleet. The agencies do not expect that elasticities estimated from 20-year old data from a single OEM's portfolio of vehicles would translate to the entirety of the current vehicle fleet.¹⁶⁴⁰ Finally, Jacobsen and van Benthem represent total vehicle demand of a representative consumer from a composite vehicle. This approach precludes the realistic consideration that a household may prefer two used vehicles over one new vehicle, which is accounted for in the agencies' functional equations.

Jacobsen's and A. van Benthem's model is not a household level choice model, and is not meant to determine fleet size, as noted in their comment:

In summary, while the Jacobsen and van Benthem (2015) paper cannot inform by how much the total vehicle fleet would expand under a CAFE rollback (since we do not estimate by how much it shrinks under CAFE), all the evidence and economic logic points to a larger total vehicle fleet under a rollback, at odds with NHTSA's fleet turnover model.¹⁶⁴¹

The agencies agree that the long-term fleet should be smaller in the augural case, as fewer new vehicles flow into the used car market (because of lower sales), but do think it is plausible that in the short term the fleet size *could* increase under augural standards if in some cases consumers substitute two used vehicles for one new one or choose to retain an additional vehicle on the margin because the higher value makes doing so a more reasonable investment (at the annual level). This sort of outcome is not possible with the Jacobsen and van Benthem 2015 model, because the overall demand for vehicles is set by the annual rent prices of a composite vehicle. The updates to the scrappage model for the final rule are consistent with this view, but do show a smaller fleet size under the augural standards relative to the proposal. This is discussed further in Section I.A.1.a)(1)(b)(iv)(b).

¹⁶⁴⁰ Kleit, Andrew N., 2004. "Impacts of Long-Range Increases in the Corporate Average Fuel Economy (CAFE) Standard." *Economic Inquiry* 42:279-94.

¹⁶⁴¹ Mark Jacobsen and Arthur van Benthem, Letter Describing Scrappage Effects, NHTSA-2018-0067-7788, at 2.

Fitting the reduced form equation requires that endogenous variables are excluded from the model to avoid biased coefficients. As a result, used vehicle prices were omitted by design, because used vehicle prices and scrappage rates are endogenous.¹⁶⁴² Some commenters argue that new vehicle prices and scrappage rates are also endogenous; CARB argued that “the model tries to rely solely on new vehicle prices to predict scrappage rates without realizing or controlling for the fact that scrappage rates may also affect new vehicle prices.”¹⁶⁴³

Commenters provided neither evidence nor an explanation as to why there may be some degree of “reverse causality” or endogeneity between new vehicle prices and scrappage rates. Two potential econometric explanations for such endogeneity could be that: 1) these variables are jointly or simultaneously determined, so each one influences the other; or 2) the model omitted a variable that causes covariance between new vehicle prices and scrappage rates. The agencies believe the first source of potential endogeneity can be dismissed, as any causal relationship between scrappage rates and new vehicle prices would *necessarily* flow through the used car market, which are substitute products for new vehicles, and specifically through the mechanism of used car prices. For example, an exogenous shock to scrappage rates *might* cause the supply curve in the market for the lowest-price used vehicles to shift, and the resulting change in their price *might* cause price responses in higher-price segments of the used vehicle market, which in turn *might* eventually filter up to the new vehicle market and affect the prices for new vehicles. This chain of events suggests omitted variable bias might be a concern, rather than simultaneity.

The agencies believe that supply and demand for used vehicles (or some measure of their interaction, such as used vehicle prices) are the most likely sources of any potential omitted variable bias. If an omitted variable is causing bias in the estimates, then the bias is observable. Whether endogeneity—through an omitted variable—is causing bias is an empirical question, which can be answered by conducting common empirical test—the Durbin-Wu-Hausman test. The Durbin-Wu-Hausman test requires identifying a suitable instrument(s)—a variable—that is correlated with new vehicle prices but not with scrappage rates, so any effect exerted on scrappage rates by the instrument will occur through their association with prices for new vehicles.¹⁶⁴⁴ The agencies tested a few alternative approaches, which included using the change in new vehicle prices during the preceding time period and the level of prices during the current period as instrumental variables for the change in prices during the current period, and another test using the current-period growth rate in GDP as an instrument for the change in new vehicle prices during the current period. Each of these tests fails to reject the null hypothesis that no endogeneity is present at the 0.05 level of significance.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

For both theoretical and empirical reasons, the agencies are therefore skeptical about both the likelihood that scrappage rates will affect prices for new vehicles, and the extent to which they might do so. The agencies find the theoretical underpinnings for endogeneity to be tenuous, and believe the empirical evidence suggests such endogeneity is not an issue for today's analysis.

The agencies chose not to fit a model predicting used vehicle prices directly from new vehicle prices for the proposal because currently-available time-series data on the prices of used vehicles of a given vintage going back to 1975 is limited. EDF cited the lack of available data as the reason not to fit the structural model:

In the absence of any data or analysis, NHTSA did not describe the extent to which changes in new vehicle prices affect used vehicle prices of varying age, condition, etc.
1645

The agencies note that acquisition, assembly, and cleaning of a nationally representative database for calendar years 1974 to 2017 on used vehicle prices by vintage from Kelly Blue Book (or a similar source) would take months to years, and would push the final rule beyond the necessary April 2020 lead time requirement to set MY 2022 standards. Kelly Blue Book data is readily searchable for current prices, but without a time series of used vehicle prices the data cannot be used to answer the causal relationship of changes in used vehicle prices over time on vehicle retirement rates. Even assembling a nationally representative sample of used vehicle prices by vintage would be a major undertaking. This is not to suggest that doing so is out of scope for future analyses; the agencies plan to consider further the possibility of conducting additional analysis on the relationship between new and used vehicle prices.

The agencies considered use of the Consumer Expenditure Survey (CEX), which has reported vehicle transaction data annually since 1984.¹⁶⁴⁶ However, the sample of used vehicle purchase prices aged twenty and older is severely limited. For vehicles purchased between 1996 and 2017, the average number of transaction prices reported for vehicles aged 20 is 58, and for vehicles aged 25 is 18. Any computation of average used vehicle prices from such a small sample would not be reliable, and in fact, would be quite noisy. The agencies do not think that estimates of a structural model based on such limited sampling would improve the prediction of the scrappage effects over use of the reduced form equation.

EDF argued that modeling the impact of changes in new vehicle prices directly on used vehicle scrappage may not capture the fact that changes in used vehicle prices impact vintages differently. Further, they argue that if new and used vehicle prices change by the same proportion, the effect will have a very small impact on the prices of the oldest used vehicles. They argue that these small changes are not enough to change the scrappage decisions:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Given that vehicles can sell for as little as a couple of hundred dollars and new vehicle prices average over \$30,000, used vehicle prices can be as little as 1% of that of a new vehicle. Given that the largest increase in new vehicle prices projected by NHTSA in the NPRM is less than \$3000, and assuming that its effect on used vehicle prices is likely to be roughly proportional to current relative prices, this might mean that the value of a very old vehicle or one in poor condition might only increase by \$30 (decline by \$30 under the proposal). It is difficult to see how such a change in value would have a measurable impact on scrappage. Of course, the impact of an increase in new vehicle prices on used vehicle prices might be more or less than proportional to their current relative values. However, NHTSA has done nothing to show which might be the case. The probability of any realistic change in used vehicle prices to induce the scrappage of used vehicles is still a complete mystery.¹⁶⁴⁷

However, the age interaction on the new vehicle price effect allows that the elasticity of scrappage to changes in new vehicle prices may not be constant for all ages. Allowing the scrappage elasticity to new vehicle prices to vary by age incorporates the fact that the elasticity of scrappage of used vehicles and the cross-price elasticity of used vehicle demand to new vehicle prices may not be constant with age. At some point, the thirty-dollar increase EDF cited could be the difference in keeping a marginally used vehicle on the road; it would be a 10 percent increase in the price of a used vehicle, and may cover State registration fees on a marginally scrapped vehicle.

(c) Time Series

The scrappage model utilizes panel data. Panel data observes multiple individuals or cohorts over time. The data employed by the scrappage model observes the scrappage rates of individual model year cohorts between successive calendar years. The model allows for the isolation of trends over time and across individuals.¹⁶⁴⁸ Since the scrappage model uses aggregate model year cohorts to estimate scrappage rates by age and time-dependent variables (new vehicle prices, fuel prices, GDP growth rate, etc.) panel data is necessary to estimate the model. A major challenge to using panel data is that the data structure requires consideration of potential violations of econometric assumptions necessary for consistent and unbiased estimates of coefficients both across the cross-section and along the time dimension. The cross-section of the scrappage data introduces potential heterogeneity bias—where model year cohorts may have cohort-specific scrappage patterns.¹⁶⁴⁹ Another way to put this is that each model year may have its own inherent durability. The NPRM captured this potential bias by including model year as a continuous variable, but the model amended for the final rule includes the more traditional individual fixed effects. This is discussed in Section I.A.1.a)(1)(c)(iii)(a). The time dimension of a panel introduces a set of potential econometric concerns present in time series analysis. The

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

agencies considered potential autocorrelation in the error structures and included lags of the dependent and specific independent variables to correct for it; this is not an uncommon practice in dynamic panel models.¹⁶⁵⁰ Some commenters argued that time series approaches were not appropriate in the scrappage model at all. CARB stated the following:

Time-series analysis for modeling scrappage is also inappropriate for the same reasons as it was for the new vehicle sales model—particularly because time-series analysis does not capture structural changes, which the scrappage model seeks to illustrate.¹⁶⁵¹

The agencies disagree with CARB's assessment. The potential scrappage effect can only be measured with a time series dimension; the agencies are interested in how changes in new vehicle prices *over time* impact the retirement rate of the on-road fleet *over time*. In order to isolate this effect, the agencies need multi-period data on the scrappage rates of used vehicles and prices of new vehicles.

The literature on vehicle scrappage rates utilizes panel data, but most research has ignored potential autocorrelation issues caused by the structural properties of independent variables that vary along the time dimension. With the NPRM analysis, the agencies found evidence of auto-correlated errors, which were corrected by including three lagged terms of the dependent variable.¹⁶⁵² While in a pure time series analysis, this can be an appropriate methodology to account for autocorrelation in the error structure; estimates of the coefficients of the lagged dependent variable are biased downwards when applied in fixed or random effects panel models. The reason for this is that the constant individual specific terms are correlated with the lagged dependent variable (by definition, since the individual specific terms are constant for all time periods, including the previous period), creating a bias in the estimate of the coefficient on the lagged dependent variable, and potentially other measures.¹⁶⁵³ The eponymous bias was first discussed in a paper written by Nickell in 1982.¹⁶⁵⁴ There is an increasing body of work developing estimators built specifically for dynamic panel data (DPD), or panel data where there is an autoregressive component to the data-generating process. In other words, the previous value of the dependent variable impacts the current value.

Further research into this literature (discussed above), comments on the NPRM, and peer review comments prompted the agencies to reconsider the approach developed for the NPRM. The NPRM analysis did not use fixed effects for specific model years, but instead imposed a parametric logarithmic relationship of successive model years. This parametric model year term will still result in biased estimates of the lagged dependent variable because it also does not vary

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

over time for the same model year, and is therefore correlated with the autoregressive term. Since the autoregressive term carries through effects from the previous period (the new vehicle price effect), this will also bias the predicted Gruenspecht effect in the NPRM model. Updates to the model used for the final rule correct this issue by more deliberately considering the time series properties of both the dependent and independent variables.

In reconsidering the appropriate way to address the time series properties of the scrappage model, the agencies first consider the stationarity of dependent and independent variables. This was suggested in James Sallee's peer review:

In contrast to the new vehicle sales regression reported in the PRIA's section 8.6, the discussion of the scrappage regressions does not include any discussion of the time series properties of the estimators. It is important to test for non-stationarity, for example.¹⁶⁵⁵

Importantly, we find that the instantaneous scrappage rate is stationary, so that there is no longer term information in the scrappage rates to recover with an autoregressive term. This means that a DPD model is not necessary to correct for potential autocorrelation in the model. This also implies that the autocorrelation in the errors is a result of non-stationarity in some or all of the regressors, and not the independent variable. The solution to this problem is to identify the order of integration of each regressor and difference until each is non-stationary. [Table II-56](#) [Table VI-136](#) in Section I.A.1.a)(1)(c)(iii)(a) shows the order of integration of variables considered in the scrappage modelling.

(ii) Modeling Fuel Economy

(a) Counterintuitive Signs

In the NPRM analysis, the agencies controlled for the changes in the relative fuel economy of new and used vehicles by including the cost per mile of travel in the current period and the previous period for both new vehicles and the model year cohort whose scrappage is being predicted. This allowed fuel prices to alter the scrappage rates of existing vehicles, meaning model year cohorts with lower-than-average fuel economies were impacted by increases to fuel prices to a greater extent than cohorts with higher-than-average average fuel economies. It also allowed increases in the fuel economy of new vehicles to impact the scrappage rates of existing vehicles; the idea is that when new vehicles have a higher average fuel economy, holding price constant, the demand for new vehicles should increase relative to used vehicles, and scrappage rates should increase. While this was a plausible way of controlling for changes in the relative fuel cost per mile of usage of new and used vehicles, the agencies noted in the NPRM that some of the signs on new vehicle cost per mile were counterintuitive, so that increases in the average new vehicle fuel economy of certain body styles actually increased the scrappage rates of existing vehicles.

¹⁶⁵⁵ *CAFE Model Peer Review* (Report No. DOT HS 812 590). Washington, D.C. – National Highway Traffic Safety Administration, B-64.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

IPI, CARB, CBD, Natural Resources Defense Council (NRDC), and other commenters argued that these results were driven more by modeling decisions than by actual relationships within the data. NRDC suggested that the conclusions from the NPRM model should be treated with suspicion until validated by further research:

[A]n increase in fuel price for a given level of fuel economy results in longer vehicle retention even though operational costs per mile increase. While it is not possible to rationalize this response without significant additional research, it is indicative of the fact that the algorithm response functions may not be properly defined.¹⁶⁵⁶

The agencies agree that the results were counter-intuitive—having identified this issue in the NPRM and specifically seeking comment on the matter—and considered multiple alternative methods of capturing the fuel economy improvements of new vehicles within the scrappage model in response to comments. Among the changes considered were alternate forms of modeling the form of new vehicle fuel economy, as suggested by IPI:

A paper by Shanjun Li et al., provides a useful example of how the agencies could include fuel efficiency in their regression without raising the econometric concerns that may be leading to their nonsensical results. Li et al. include fuel price and vehicle fuel efficiency (gallons per mile) of used vehicles as well as a variable that captures the interaction of fuel efficiency of used vehicles and fuel price in their regression as explanatory variables. [Footnote 407: Li et al. (2009), at 127.] Unlike the agencies' model, the regression analysis used in the Li et al. paper found results that are consistent with economic theory: a decrease in overall demand for vehicles and an increase in demand for more fuel-efficient cars.¹⁶⁵⁷

The NPRM included changes in new vehicle cost-per-mile, but did not include separate variables for fuel prices or fuel economy. This could potentially have conflated changes in the cost-per-mile of new vehicles from changes in fuel prices and changes in new vehicle fuel economy. The agencies considered including changes in fuel prices and new vehicle fuel economy as separate measures, as suggested in IPI's comment above, but opted for a different method of addressing the concern of how to include changes to new vehicle fuel economy in the scrappage model. However, specifications considering this approach are shown in Section I.A.1.a)(1)(c)(iii)(d).

(b) New Vehicle Prices Net of Fuel Savings

UCS, CBD, NRDC, EDF, and other commenters expressed concern that quality adjustments were not included in the price series used to fit the NPRM model. In particular,

¹⁶⁵⁶ NRDC, Attachment 3: CAFE Model Activity Review, NHTSA-2018-0067-11723, at 20.

¹⁶⁵⁷ IPI, Policy Integrity Comments: NHTSA Final- Appendix, NHTSA-2018-0067-12213, at 72.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

commenters suggested that the valuation of fuel savings at the time of purchase should be deducted from the new vehicle price increases. For example, CBD argued:

. . . [T]he agencies rely heavily on work by Howard Gruenspecht regarding the scrappage effect, and the NPRM acknowledges that Gruenspecht considered the effect of an increase in price “net of the portion of reduced fuel savings valued by consumers.” Yet consumer valuation of fuel savings is excluded from the scrappage model, as well.¹⁶⁵⁸

The scrappage model cannot include both independent variables on the fuel economy and cost-per-mile of new vehicles, and adjust the new vehicle prices by the value of fuel savings considered at the time of purchase, which would account for the improvement of the fuel economy of new vehicles twice. Thus, the agencies must choose between these methods to capture the value improvement of new vehicles when their fuel economy increases. The agencies show both methods in Section I.A.1.a)(1)(c)(iii)(d). However, additional comments give reason to prefer a methodology that does not model the fuel economy or cost per mile of new model year cohorts directly, but instead adjusts the new vehicle price series by the amount of fuel savings valued at the time of purchase.

IPI expressed concern that the cost-per-mile measure was included in the scrappage model, but not in the sales model:

[T]he CPM results in the scrappage model are inconsistent with the agencies’ sale model. In the sales module, the agencies have chosen to ignore consumer demand for fuel economy and significantly boosted the price impact of the baseline standards as a result. But in the scrappage model, the agencies have incongruously allowed consumer valuation of fuel economy to drive a significant portion of the estimated fatalities.¹⁶⁵⁹

The agencies note that the fuel economy of new vehicles was not included in the sales model because the signs were statistically insignificant when it was included, and the fit of the overall model was not improved. It was not excluded because the agencies do not think that new vehicle fuel economy does not affect their sales. One way to consider the value of increased fuel economy in both the sales and the scrappage model (in the same way) is to adjust the price of new vehicles by the amount of fuel savings consumers value at the time of purchase in both models. This is also consistent with how the CAFE model applies technology in the absence of CAFE standards, or when a manufacturer is already in compliance with existing standards. In response to comments about the counterintuitive signs of the change in new vehicle cost per mile for some body styles, and about the disconnect in how the fuel economy of new vehicles is modelled in the sales and scrappage models, the agencies have adjusted the new vehicle price series in both models by the amount of fuel savings consumers are assumed to value at the time of purchase (30 months of fuel savings). As noted in Section I.A.1.a)(1)(b)(ii)(a), alternatives to this solution are presented in Section I.A.1.a)(1)(c)(iii)(d). The agencies also discuss

¹⁶⁵⁸ CBD, Appendix A, NHTSA-2018-0067-12000, at 177.

¹⁶⁵⁹ IPI, Policy Integrity Comments: NHTSA Final- Appendix, NHTSA-2018-0067-12213, at 79.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

consideration of other quality improvements over successive model years in Section I.A.1.a)(1)(b)(iii)(d).

(iii) Consideration of Other Additional Variables

Some commenters expressed concern that the scrappage model implemented in the NPRM analysis omitted several theoretically important variables in predicting the scrappage rates of the existing vehicle fleet. To understand these comments more fully it is useful to recall that existing vehicle owners can be private households/individuals, businesses, or dealerships. They supply the used vehicle (in the sense of making it available for use) to the market either by reselling them, or continuing to own the vehicle for their own use. Theoretically an existing owner will supply a used vehicle for additional use if the value of the vehicle (net of the opportunity cost of its value as scrap metal and used parts) exceeds the cost of maintenance, repair, insurance, and registration fees for the vehicle. If a seller does not perform necessary repair or maintenance services on the vehicle prior to sale, the value of the vehicle should be offset by the cost of those services. Accordingly, the scrappage threshold for a vehicle should remain the same regardless of whether the seller or buyer pays for any necessary maintenance or repair services on the vehicle.

Under this framework, commenters have argued that the agencies should include maintenance and repair costs, the value of the used vehicle when scrapped, and other costs to purchase the vehicle, all of which were excluded in the NPRM version of the scrappage models. IPI stated the following:

The agencies should include the variables that Gruenspecht and others have traditionally included in their scrappage analysis, including price of vehicles indexed by maintenance and repair costs, the price of scrap metal, and interest rates.¹⁶⁶⁰

The agencies agree that these variables are relevant to determining the scrappage rates of existing vehicles, but have concerns that the level of aggregation of available series related to each of these factors may obscure the ability of a statistical model to capture their impact on vehicle scrappage rates. Below, we discuss commenter concerns about the omission of maintenance and repair costs, scrap steel prices, and interest rates, in turn. We then outline the agencies' further consideration of each factor in this final rule analysis, and why each chose whether to consider each factor in the analysis for the final rule. Empirical results of models considering these factors are shown in Sections I.A.1.a)(1)(c)(iii)(e) and I.A.1.a)(1)(c)(iii)(f); the decision to exclude them from the primary analysis is further explained in these sections.

¹⁶⁶⁰ IPI, Policy Integrity Comments: NHTSA Final- Appendix, NHTSA-2018-0067-12213, at 91.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(a) Maintenance and Repair Costs

EDF, IPI, California States et. Al., CARB, CBD, and other commenters suggest that the omission of maintenance and repair costs by the agencies was not justified, and that the measure should be included in future models. CARB claimed that:

parameters for repair costs and used vehicle prices towards the end of life should likely be included in a scrappage model. However, neither of these variables appear in the Agencies' model.¹⁶⁶¹

The agencies agree that the theoretically ideal model of scrappage would include maintenance and repair costs. For this reason, the agencies explored several methods for explicitly incorporating maintenance and repair costs. Section I.A.1.a)(1)(c)(iii)(f) reports model results both with and without a maintenance and repair variable. Since the variable is integrated of order one, (see [Table II-54](#)~~Table VI-134~~), the models including it take the first difference; in this form, increases in maintenance and repair costs result in an increase in the scrappage rate of existing vehicles, as expected. The sign is also statistically significant. While the agencies would prefer a maintenance and repair price series that varies by calendar year and vintage, such a series is not currently available. We hope to continue to improve this variable in future work on the scrappage model, but respond to comments by including the first difference of the maintenance and repair series in some of the models considered for the model used for the final rule.

Commenters were apparently confused about the agencies' discussion of the impact of fuel economy standards on durability. The agencies discussed a finding from the Greenspan and Cohen (1996) paper that suggested that higher EPA emission standards actually decreased the durability of certain model years. The discussion from the PRIA follows:

In addition to allowing new vehicle prices to affect cyclical vehicle scrappage à la the Gruenspecht effect, Greenspan & Cohen also note that engineering scrappage seems to increase where EPA emission standards also increase; as more costs goes towards compliance technologies, it becomes more expensive to maintain and repair more complicated parts, and scrappage increases. In this way, Greenspan and Cohen identify two ways that fuel economy standards could affect vehicle scrappage - 1) through increasing new vehicle prices, thereby increasing used vehicle prices, and finally, reducing on-road vehicle scrappage, and 2) by shifting resources towards fuel-saving technologies—potentially reducing the durability of new vehicles by making them more complex.¹⁶⁶²

¹⁶⁶¹ CARB, Detailed Comments, NHTSA-2018-0067-11873, at 244.

¹⁶⁶² PRIA at 1000.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

EDF and IPI misinterpret the agencies' discussion of findings from Greenspan and Cohen's work to imply that the fuel efficiency variable is meant to control for changes in maintenance and repair costs. The following quote from IPI exemplifies their confusion:

In addition, the agencies have explicitly excluded several theoretically important explanatory variables (e.g., the cost of maintenance and repair), which are potentially correlated with fuel efficiency. [Footnote 405: Id. at 1000 (indirectly making this point with respect to fuel efficiency and maintenance and repair costs when emphasizing that 'Greenspan & Cohen also note that engineering scrappage seems to increase where EPA emission standards also increase; as more costs goes towards compliance technologies, it becomes more expensive to maintain and repair more complicated parts, and scrappage increases'). In other words, maintenance and repair costs are correlated with respect to fuel efficiency and scrappage rates.]¹⁶⁶³

The agencies did not mean to imply that including some measure of the fuel economy of a model year cohort (cost per mile, in the NPRM model) would control for variation in maintenance and repair costs over time. The discussion of Greenspan and Cohen's results was intended only to demonstrate that durability and standards that increase technological complexity may be correlated, so that durability increases may not be independent of CAFE/CO₂ standards.

Maintenance and repair costs for a given model year cohort likely are correlated with the fuel saving technologies applied to that cohort, but there is also a dimension of maintenance and repair costs that are correlated with other macroeconomic factors (i.e., wages, materials, etc.). Controlling for fuel economy would not capture calendar-year-specific changes to maintenance and repair costs that are caused by factors other than fuel economy. It also does not seem likely that variation in maintenance and repair costs from different fuel savings technology would be linearly related to fuel consumption, so that even model year variation in maintenance and repair costs could not be captured by including some measure of fuel economy or fuel consumption. As noted above, the agencies agree that maintenance and repair prices exist in the theoretically ideal scrappage model, and consider the variable in some of the models presented in Section I.A.1.a)(1)(c)(iii)(f).

(b) Scrap Values

In the NPRM model, the agencies considered inclusion of the BLS scrap steel CPI series. We gave the following reasons for excluding the measure in the final NPRM models in the PRIA:

As noted by Parks (1977), the value of a scrapped vehicle can be derived either from the value of recoverable scrap metal or from the value of sellable used parts. There are several issues with using the BLS scrap steel CPI. First, as in Park's work, the coefficient on scrap steel is statistically insignificant—model results including the CPI of scrap steel are not shown, as there were other theoretical problems with the measure. The

¹⁶⁶³ IPI, Policy Integrity Comments: NHTSA Final- Appendix, NHTSA-2018-0067-12213, at 78.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

material composition and mass of vehicles has changed over time so that the absolute amount of recoverable scrap steel is not constant over the series. The average weight of recoverable steel by vintage would have to be known, and this measure would still be missing any other recoverable metals and other materials. Further, projecting the future value of the recoverable scrap metal would involve computing the amount of recoverable steel under all scenarios of fuel economy standards, where mass and material composition are assumed to vary across all alternatives. This value is not calculated explicitly in the current model, which is another reason some estimate of the value of recoverable metal is not included in the preferred model specification.¹⁶⁶⁴

The concerns the agencies raised in the NPRM continue to be present for the model used for the final rule. The BLS scrap steel CPI will not have the same effect on the opportunity cost (the scrap value) of keeping an existing vehicle on the road as opposed to scrapping it for successive model year cohorts. The average weight of vehicles has changed over successive model years, as has the average steel composition.

Even considering the limitation of using the BLS scrap steel price series, commenters expressed concern about the exclusion of a variable to capture changes in the value of a vehicle as scrapped metal and/or used vehicle parts. As noted in Section I.A.1.a)(1)(b)(iii)(a), IPI suggested that “the price of scrap metal” should be included, while CARB suggested the model include “used vehicle prices towards the end of life.” The agencies made several further attempts to capture this component of vehicle scrappage, and address commenters’ concerns, in the scrappage models used in the final rule. We continue to consider models which include the BLS iron and scrap steel CPI series; results of these considerations are shown in Section I.A.1.a)(1)(c)(iii)(f).

(c) Interest Rates

IPI and EDF expressed concerns that changes in the real interest rates of vehicle loans had not been included in the final NPRM scrappage model. EDF commented the following:

NHTSA’s model also does not include interest rates or the cost of financing a vehicle, another variable which NHTSA acknowledges affects scrappage. NHTSA itself states that “[a]s the real interest rate increases so does the cost of borrowing and the opportunity cost of not investing. For this reason, it is expected that as real interest rates increase that vehicle scrappage should decline. Consumers delay purchasing new vehicles because the cost of financing increases. Conversely, as real interest rates decrease, vehicle scrappage should increase Yet, NHTSA chooses not to include interest rates in its model since inclusion of interest rates yields results that are opposite to what is expected—“as real interest rates increase, so does the scrappage rate” in NHTSA’s model. As discussed

¹⁶⁶⁴ PRIA at 1012,

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

above, this is yet another indication that the model is flawed and cannot be relied upon.¹⁶⁶⁵

The agencies considered real interest rates in the NPRM analysis. Increasing the cost of purchasing a vehicle should increase the incentive for households to hold onto existing vehicles (as opposed to purchasing one) and scrappage rates should decline. We excluded real interest rates from the final NPRM model for the reasons stated in the PRIA:

Table 8-14, Table 8-15, and Table 8-16 include interest rates and maintenance and repair CPI for cars, vans/SUVs, and pickups, respectively. For cars, as shown in Table 8-8, real interest rate is of the opposite sign than expected; as real interest rates increase, so does the scrappage rate—this model is also a worse fit by measures of AIC and BIC relative to the preferred model.¹⁶⁶⁶

In response to commenters' concerns, the agencies continue to consider interest rates in the model used for the final rule, as shown in Section I.A.1.a)(1)(c)(iii)(e). However, interest rates only affect scrappage rates where a household might be unable to finance the purchase of a new or used vehicle and instead decides to maintain an existing vehicle that would have otherwise been scrapped. The most likely substitute for a marginal scrapped vehicle would not be a vehicle that could be financed. Accordingly, the relationship between interest rates and scrappage rates may be weaker than that between new vehicle prices and scrappage rates. The most likely substitutes for new vehicles are vehicles just off lease, and the resulting increase in residual values will affect slightly older vehicles. Eventually, the price of the most likely substitutes for marginally scrapped vehicles will also increase, so that scrappage rates will also be affected.

(d) Other Vehicle Quality Adjustments

CARB and other commenters expressed concerns that the NADA series used by the agencies in development of the NPRM scrappage model did not make quality adjustments. CARB made the following specific comment:

By only including new vehicle prices and no other controls for vehicle quality, the Agencies' scrappage model omits variables that are important predictors of scrappage rates and of vehicle prices. Prior work that has relied on new vehicle prices to estimate scrappage rates have also included some aspects of quality improvements, meaning considering that the vehicle is improving in some way. For example, Greenspan and

¹⁶⁶⁵ EDF, Appendix A, NHTSA-2018-0067-12108, at 41.

¹⁶⁶⁶ PRIA at 1028.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Cohen (1996) include both the Bureau of Labor Statistics (BLS) new vehicle price index and the BLS cost of repair index.¹⁶⁶⁷

The NADA average new vehicle transaction price does not control for other average characteristics that may change over successive model years. The agencies considered controlling for average body style and model year characteristics in the scrappage model as an alternative to including fixed effects in the model. The considered characteristics included: horsepower to weight, zero to sixty acceleration time, and average curb weight. However, performing the *pFtest* implementation of an F-test of goodness-of-fit, from the “plm” R package, suggested that fixed effects are necessary to control for heterogeneity across model years.¹⁶⁶⁸ For this reason, average characteristics that are constant over calendar years for a given model year cohort cannot be included in the model. We do present specifications that include the ratio of new to used vehicle performance (since this has calendar year level variation and can be included with model year fixed effects) in Section I.A.1.a)(1)(c)(iii)(f).

(iv) Integration of Sales and/or VMT, Total Fleet Size, and Total VMT

Some commenters believe the ideal model of how CAFE/CO₂ standards affect sales, scrappage, and usage would be a joint household choice model. RFF makes the following comment:

The agencies can fix those problems by making two changes. First, they can jointly model VMT and vehicle holdings (i.e., scrappage and new-vehicle purchases). The literature provides many examples of such modeling for guidance (see citations above). Jointly modeling these choices will make the analysis internally consistent and will account for the fact that households do not make scrappage and vehicle use decisions in isolation. If the model predicts that weaker standards cause more scrappage, it will simultaneously estimate any increase in VMT for the remaining vehicles.¹⁶⁶⁹

The advantage of such a model is that sales, scrappage, and usage would be jointly determined so that the impacts on scrappage is conditional on how increased new vehicle prices affect sales and vehicle prices, and usage is dependent on both effects. The agencies agree that this type of model would better capture the joint nature of the choices of which vehicles to buy, which to sell or scrap, and how much to use each than modelling each effect separately. However, the agencies are not aware of any national dataset that would allow sales, scrappage and usage to be jointly predicted, nor are they confident of such a model’s ability to predict better than carrying current market shares forward.

¹⁶⁶⁹ RFF, Comments EPA NHTSA, NHTSA-2018-0067-11789, at 14.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The papers cited in the RFF comment, Linn and X. Dou, 2018;¹⁶⁷⁰ Berry, Levinsohn, and Pakes, 1995;¹⁶⁷¹ and Jacobsen and van Benthem, 2015,¹⁶⁷² either use the CEX or the NADA transaction price series merged with the Polk registration counts. The CEX is a relatively small sample of households (about 160,000), their vehicle holdings, vehicle purchases, and usage. However, it does not report retirement rates, but only when a vehicle exits a household's fleet (most often it is sold or traded in). Thus, at best, the CEX could be used to build a household consumer vehicle holdings and usage model, but the vehicles that are scrapped would be implied; scrappage would not be modeled directly, nor would it be attached to the number of miles on a vehicle. The NADA and Polk datasets used by Jacobsen and van Benthem links vehicles prices and scrappage rates, but does not track individual household decisions. The Jacobsen and van Benthem paper relies instead on a model of the new and used vehicle market which takes cross-price elasticities as an assumption derived from the outputs of a 1997 GM consumer choice model.^{1672+574, 1673} The agencies will continue investigating whether a consumer/household choice model can serve as an alternative to aggregate estimates of sales and scrappage, but are skeptical about the ability of such models to predict future model shares accurately.

As was the case with the 2012 final rule and the 2016 TAR, the agencies again note there is no credible consumer choice model which can be implemented in the CAFE model. Literature comparing the performance of consumer choice models to holding manufacturers constant suggest that the latter predicts future market shares better than the former. NCAT raises this point in their comment below:

Academic and other researchers have developed a number of vehicle demand (consumer choice) models for the new and/or used vehicle markets to look at effects on sales and fleet mix. Rarely has there been any effort to validate these models, either for consistency across models, or for ability to predict out of sample. Recent academic research, as well as work by EPA, has found that these models commonly perform worse, especially in the short run, than simply holding market shares constant.¹⁶⁷⁴

For these reasons, the agencies have not used a consumer choice model to capture the sales and/or scrappage impacts, but have built reduced form equations from aggregate data instead.

¹⁶⁷³ Kleit, Andrew N., 2004. "Impacts of Long-Range Increases in the Corporate Average Fuel Economy (CAFE) Standard." *Economic Inquiry* 42:279–94.

¹⁶⁷⁴ NCAT, NCAT Comments, NHTSA-2018-0067-11969, at 11.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NCAT and CBD also refer to EPA attempts to develop a consumer choice model in conjunction with Oak Ridge National Labs, and note that the agencies did not use this model for the NPRM analysis. This specific choice model, as referenced in the excerpted NCAT comment above, has not predicted future market shares as well as projecting current shares forward. For this reason the model was not deemed fit to include in the policy analysis. NHTSA also worked to develop a consumer choice model, but when implemented, the model predicted that some OEM's would have unrealistic declines in total sales. The limitations of the consumer choice models the agencies have considered is overlooked in the following comments from CBD:

The sales model the agencies use is not the consumer-choice model that EPA has been developing and refining for almost a decade. Rather, both it and the scrappage model appear to have been developed by NHTSA in just the last two years. Neither model has been peer-reviewed, nor even released publicly until the publication of this NPRM.¹⁶⁷⁵

The agencies did not use the consumer choice models either agency developed because the predictions are not reliable—which has disappointed not only the commenters mentioned above, but the agencies and researchers who have spent significant resources attempting to develop models for these purposes. Instead, the agencies have modelled the effects from reduced form equations from aggregate data.

(a) Integration with Sales Model

The NPRM models did not include any direct linkage between the sales, scrappage, and usage functions, as noted by the agencies. Here, the agencies consider comments from stakeholders about the lack of integration of the scrappage model with sales (and the effect on total fleet size), and the lack of integration with the vehicle usage schedules (and the effects on total VMT).

NCAT, EDF, CBD, CARB, and other commenters argued that the sales and scrappage models should be directly linked, and that their independence predicts the higher fleet size and total VMT under the augural standards. CBD makes the following statement:

The agencies now, irrationally, decouple those two effects, such that the number of new vehicles sold (or left unsold) has no effect on the number of vehicles scrapped. Relying on the deeply flawed scrappage model, the agencies have predicted a massive ballooning of fleet size under the existing standards that leads, automatically under their model, to a massive increase in VMT.¹⁶⁷⁶

The agencies note that the structural model presented in Section I.A.1.a)(1)(b)(i)(b) demonstrates that both the equilibrium quantity and the price of new vehicles sold are changed when the production cost of new vehicles changes under different regulatory alternatives. Specifically, under relaxed standards, the equilibrium price is lower and equilibrium sales are

¹⁶⁷⁵ CBD, Appendix A, NHTSA-2018-0067-12000, at 175.

¹⁶⁷⁶ CBD, Appendix A, NHTSA-2018-0067-12000, at 185.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

higher than the counterfactual augural standards. Controlling for other variables that might shift the new vehicle supply or demand curves, either new vehicle prices or sales could enter the used vehicle demand equation (as in the structural model, there is a functional relationship between the two, again, controlling for factors that shift the supply and demand curves for new vehicles). Thus, the agencies could use either new vehicle sales or prices to control for changes in the new vehicle equilibrium solution in the scrappage equation. It is important to control for factors that affect the demand for vehicles overall (business cycle conditions, etc.). The agencies present the preferred models using either new vehicle prices or new vehicles sales in Section I.A.1.a)(1)(c)(iii)(d). Since there should be a collinearity between the two, it would be inappropriate to include both variables simultaneously.

(b) Total Fleet Size

NCAT, EDF, CBD, CARB, UCS, IPI, California et. al., academic commenters, and other stakeholders argue that the fleet size should not change much with new vehicle prices. Some commenters go further to argue that higher vehicle prices under the augural standards should result in a *smaller* fleet size in the augural case relative to the proposal. The agencies agree that the long-term impact of higher new vehicle prices should be a slight reduction in fleet size, but do not agree that the short-term impacts of the standards on fleet size are obvious.

Many examples from the literature make assumptions that ensure that the fleet size under different regulatory alternatives remain constant. UCS cites this assumption in the original Gruenspecht works (their emphasis):

Though the agencies cite the Gruenspecht effect for its basis for the scrappage model, they ignore a central constraint of Gruenspecht's work—namely, his assumption that FLEET SIZE AND TOTAL VMT ARE INSENSITIVE TO PRICE.¹⁶⁷⁷

Other works ensure the same conclusion with different assumptions. Within the Jacobsen and van Benthem, 2015 and Goulder et. al., 2012 framework, a household first chooses the number of vehicles to own based on the average price of all vehicles subject to a budget constraint. After choosing the number of vehicles to hold, the household chooses the specific type and age of vehicles to hold. However, for some households the choice of how many and which vehicles to hold is not disjoint, so that a household may choose to hold two used vehicles as a second choice to one new vehicle. When new vehicle prices increase, under the same budget constraint, they may choose to hold two vehicles instead of one. If enough households make this choice, the fleet size could slightly increase.

IPI gives a literature example of a model that does not ensure this outcome with initial assumptions. This model directly predicted fleet size, and not sales and scrappage. The fleet size in the CAFE model is the result of the sales and scrappage models, and not the result of a

¹⁶⁷⁷ UCS, UCS MY2021-2026 NPRM: Technical Appendix, NHTSA-2018-0067-12039, at 60.

single of the models. Small and Van Dender, 2007 finds that higher new vehicle prices are associated with lower total vehicle stock, as IPI states in the quote below:¹⁶⁷⁸

In their 2007 study estimating the rebound effect caused by changes in fuel efficiency, Kenneth Small and Kurt Van Dender derived estimates of the relationship between vehicle price and fleet size. By simultaneously estimating a system of equations for VMT per capita, fleet size, and fuel efficiency for the United States from 1966 to 2001, Small and Van Dender also found that an increase in new vehicle price has a negative, statistically significant effect on total vehicle stock.¹⁶⁷⁹

However, it is worth noting that Hymel, Small, and Van Dender in 2010 published a study finding a statistically insignificant result of the opposite sign.¹⁶⁸⁰ The general framework of the two papers are very similar, so that the updated results show that the fleet size impact is ambiguous.

Toyota and the Automobile Alliance mentioned that NERA built sales and scrappage models, and requested that the agencies “review the NERA econometric study’s methodologies for adoption or to refine their own models.” The agencies considered the NERA scrappage model, but note that the model merges the data for all vehicle types, so that the scrappage relationship by age for pickups is adjusted by the same constant for all ages. However, the agencies note that each body style has a unique functional form with age—as evidenced in Section I.A.1.a)(1)(c)(iii)(c)—so that it does not seem appropriate to merge them. Further, it does not seem likely that the elasticity of scrappage is the same for all vehicle types.

While the agencies think there are reasons not to adopt the NERA scrappage model as is, this suggested general approach does support simplifying the model as further suggested in Section I.A.1.a)(1)(b)(i). Also, this research supports the notion that the relative fleet size of the proposed and augural standards is not a given. NERA’s comments about their model provided:

The separate changes in new vehicle sales and changes in scrappage rates would lead to differences in the overall fleet size for the CAFE standard alternatives. The net effects of these two changes did not have a substantial effect on the overall fleet population under any of the three CAFE alternatives (never more than 0.25% change in fleet size compared to the augural standards).¹⁶⁸¹

The NERA model shows the same directional fleet impacts as the NPRM sales and scrappage model. This lends some further support to the notion that the fleet impacts are not as certain as some commenters suggest.

Another empirical model predicts a larger total fleet size under the augural standards than under the proposed standards. Comments by David Bunch offer an extended comparison of the sales, fleet size, and retirement rate results of the Department of Energy's National Energy Modeling System (NEMS) model under the proposed and augural standards. NEMS predicts fleet size from input assumptions about the size of the on-road fleet, endogenous new vehicle sales estimates, and exogenous assumptions about scrappage.¹⁶⁸² However, in his comments Bunch said:

Scrappage is an implied behavior determined by projecting total fleet size and new vehicle sales. Through this mechanism, all else equal, an increase in new vehicle sales would yield an increase in scrappage.¹⁶⁸³

NEMS does not project total fleet size endogenously in their model as Bunch assumes. Nor is scrappage an implied behavior determined by fleet size and new sales projections. Instead, total fleet size is implied from an endogenous sales model, and constant age- and body-style-specific scrappage rates. The difference between the CAFE Model and NEMS is that the CAFE model has both endogenous new vehicles sales *and* scrappage rates—scrappage rates are not assumed to be constant for all regulatory alternatives. Fleet size is the implied variable in *both* models.

Bunch finds that the NEMS model also predicts a larger fleet size under the augural standards than the proposed standards. Specifically, he finds the following:

The differences are initially about 100K, increasing linearly from 2031 from 200K to 1.8M in 2050. Because even the Existing standards remain at the same level after 2025, this would seem to represent a very different effect from what might be going on in the CAFE model results.¹⁶⁸⁴

Bunch goes on to discuss the relationship between sales, scrappage and fleet size in NEMS in the following passage:

New vehicle sales generally are growing in both scenarios, so economic theory suggests that fleet sizes should also be growing (they are). Specifically, although the Gruenspecht effect logic suggests that increasing new vehicle sales should lead to increased used vehicle scrap rates, the total “value” of the fleet is increasing, so this would suggest an

¹⁶⁸² From page 109 of 2016 NEMS documentation “*exogenously* estimated vehicle scrappage and fleet transfer rates.” [https://www.eia.gov/outlooks/aeo/nems/documentation/archive/pdf/m070\(2016\).pdf](https://www.eia.gov/outlooks/aeo/nems/documentation/archive/pdf/m070(2016).pdf).

¹⁶⁸⁴ David Bunch, Bunch-UC Davis: Consumer Behavior Modeling, at 69.

increase in the fleet size. Moreover, new vehicle sales are higher under Existing, so the fleet size should be also.¹⁶⁸⁵

Bunch makes several claims that are not consistent with available data and the agencies' understanding of how the NEMS model. First, he states that because sales are growing fleet size should also be growing. However, change in fleet size is the result of new vehicle sales less the number of existing vehicles scrapped; if new vehicle sales and used vehicle scrappage rates both increase, the fleet size is not necessarily increasing. Second, he states that the 'Gruenspecht effect logic' suggests that increasing new vehicle sales results in increasing scrappage rates. However the NEMS model does not change vintage-specific scrappage rates endogenously, but takes them as an exogenous input. Thus, the NEMS model does not capture the Gruenspecht effect, and its fleet size projections can only vary from changes in new vehicle sales. Any differences in the projected total fleet scrappage rates Bunch considers later are due to different initial sales of each body style, and therefore a different weighting of the constant body-style- and vintage-specific scrappage rates. This makes the comparison of the fleet size and scrappage rates of the two models not particularly meaningful. However, the difference in the projected sales impacts are worth a second glance. NEMS predicts prices that are at most about \$1,000 higher in the Augural than the proposed standards, while the CAFE model predicts prices that are up to approximately \$2,500 higher. The difference in the projected costs to meet the CAFE standards is likely the main reason for the difference in the sales outcomes—if the average fuel savings exceed the average incremental cost of the augural standards (relative to the proposal) in the NEMS model, the expected outcome is that sales should be higher in the augural case, as shown.

It is also worth noting Bunch's discussion of the empirical results of the CAFE scrappage model. Bunch purports to calculate the scrappage elasticity relative to new vehicle price increases, but his point of comparison does not hold constant other factors that might impact used vehicle scrappage rates. Instead, Bunch calculates the inter-annual percentage change in the scrappage rates for each regulatory alternative, then calculates the inter-annual change in new vehicle prices for each regulatory alternative, and finally takes the quotient. However, for inter-annual changes in scrappage rates, different projected GDP growth rates and fuel prices will have also played a critical role in the scrappage rates. The better point of comparison would be the incremental percentage decrease in scrappage rates for the augural standard relative to the proposal, over the incremental percentage increase in new vehicle price in the augural standard relative to the proposal for each calendar year. This ensures that the point of comparison holds constant all other factors that determine scrappage, as the regulatory alternatives use the same GDP growth rate and fuel price projections. When computing the implied scrappage elasticity in this way, the implied elasticities vary between approximates -0.1 and -1.1, with the average being approximately -0.5—which is *more* in line with what Bunch determines reasonable for his incorrect calculations of the NEMS model scrappage elasticities, as cited below:

¹⁶⁸⁵ David Bunch, Bunch-UC Davis: Consumer Behavior Modeling, at 71.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Finally, the average values are -0.90 and -0.88 for the Existing and Rollback scenarios, respectively. On one hand, these are reasonably close to the Jacobsen and van Benthem (2015) estimate for scrap elasticity with respect to used vehicle prices. On the other hand, the Bento et al. (2018) estimate was -0.4, and one might expect the elasticity with respect to new vehicle price to be smaller. In any case, these results are not unreasonable.¹⁶⁸⁶

The implied elasticities from the NEMS model are approximately zero, which is not a surprise since these are merely the result of different new vehicle sales affecting the relative weighting of NEMS' *constant* age-specific scrappage rates. **Figure II-27 - Fleet Size Comparisons** **Figure VI-52 - Fleet Size Comparisons** **Figure II-27** **Figure VI-52**, below, shows a comparison of fleet sizes under the baseline, preferred alternative, and AEO 2019. We see that, as commenters believed likely, the fleet size under the preferred alternative (where sales are larger in many years and scrappage rates higher) is eventually larger than in the baseline. However, those differences are minimal in the early years of the simulation where policy differences produce only small differences in sales and scrappage. Furthermore, we see that the magnitudes of the fleet sizes in today's rule are generally similar to those produced by the AEO 2019 model. NEMS tends to produce growth that is more linear, leading to slightly smaller fleet sizes than those simulated by the CAFE Model through the 2030's and slightly larger fleet sizes through the 2040's. However, these differences are at most three percent of fleet size, and typically closer to one or two percent.

¹⁶⁸⁶ David Bunch, Bunch-UC Davis: Consumer Behavior Modeling, at 79.

Figure II-2758 - Fleet Size Comparisons

As discussed above, commenters offered NERA's model and NEMS as points of comparison for NHTSA's sales and scrappage models and their combined implied fleet size. However, since NEMS does not model the scrappage effect, but takes static scrappage rates, it is not a fair point of comparison. NERA's model shows a larger fleet under the Augural standards, providing evidence that the impacts of the sales and scrappage models are ambiguous.

(c) Integration with VMT

In the NPRM the agencies noted that the average VMT by age is constant regardless of instantaneous or cumulative scrappage rates. We noted that this was a limitation of the model, and sought comment on ways to integrate the two effects:

[O]ur scrappage model assumes that the average VMT for a vehicle of a particular vintage is fixed—that is, aside from rebound effects, vehicles of a particular vintage drive the same amount annually, regardless of changes to the average expected lifetimes. The agencies seek comment on ways to further integrate the survival and mileage accumulation schedules.¹⁶⁸⁷

Several commenters suggest that the lack of integration between VMT and scrappage rates is not justified. Some commenters suggested that the VMT should be determined from a household holdings model, while others suggested merely that delayed scrappage under higher standards should increase average mileage accumulation, which will have some feedback for the next year's scrappage rates.

Joshua Linn and other commenters suggest that VMT is determined at the household level and should thus be modelled as such. EDF makes the following comment, which seems to reflect a fundamental misunderstanding of the type of model used to predict the scrappage effect:

When describing the process whereby a potential new vehicle purchaser chooses to forego buying a new vehicle and continues to drive their existing vehicle, NHTSA's scrappage model ignores the fact that this action shifts VMT from a new vehicle with a higher average mileage per year to a used vehicle with a lower average mileage. Either the driver of this vehicle will drive their older vehicle less, causing overall VMT to decline, or the average mileage of the used vehicle will increase without any need to affect scrappage. By focusing solely on scrappage, and focusing the change in scrappage on those vehicles with the worst fuel economy (i.e., the oldest vehicles), NHTSA essentially shifts new vehicle VMT to the oldest vehicles. According to NHTSA's own rationale, much of the lost VMT from new vehicles will be replaced by vehicles only a

¹⁶⁸⁷ EDF, Appendix B, NHTSA-2018-0067-12108, at 51.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

few years old. The VMT of these relatively new used vehicles which is then replaced by VMT from older used vehicles, and so on.¹⁶⁸⁸

The agencies' scrappage model does not capture household choices, but uses aggregate data to predict new vehicle sales and age-specific scrappage rates in response to changes in new vehicle prices. In addition, the scrappage rates of all ages change in response to increases in new vehicle prices, not just the oldest vehicles. Further, the household that does not buy a new vehicle but holds onto an existing vehicle instead, in EDF's example, results in one fewer used vehicle supplied to the used market—this will result in an increased price for used vehicles and potentially lead to some used vehicles not being scrapped. Because the VMT schedules the agencies use in modelling show usage declining with age, the agencies' model does assume that younger vehicles that are not scrapped are driven more than older vehicles that are not scrapped.

EDF, IPI, and Honda further argue that mileage accumulation should not be constant under all scrappage rates. Specifically, they suggest that the assumption that average VMT accumulation by age is constant even when scrappage rates decline, results in an *overestimate* of VMT. IPI suggests that the marginally unscrapped vehicles should drag down the average VMT accumulation under higher standards in the following comment:

Because those schedules assume each vehicle of a certain age and type in the fleet drives a set amount of miles without any adjustment for the increase in total fleet size or vehicle quality (i.e., wear and tear and durability), the finding that the standards cause the fleet size to increase results in a significant increase in total VMT.¹⁶⁸⁹

The agencies note that mileage accumulation and scrappage are not disjoint. A vehicle that is driven more miles is more likely to be scrapped. However, since the National Vehicle Population Profile (NVPP) data does not track individual vehicles, there is no obvious way to merge individual vehicle odometer readings with those that are scrapped. The agencies hope to continue to investigate data sources that may quantify the joint relationship of the two effects, and better respond to the claims from EDF that "NHTSA presents no data or analysis to justify this assumption."¹⁶⁹⁰ In the meantime, the agencies have adjusted the final rule analysis to conservatively assume that total demand for VMT, not including the rebound effect, should be constant for all regulatory alternatives, as discussed in Section I.A.1.a)(1)(b)(iv)(d), below. This requires that the VMT schedules are no longer constant for all fleet sizes.

(d) Total VMT

Many commenters think that total VMT, not considering rebound miles, should be constant, regardless of the number of new vehicles sold and used vehicles scrapped. NCAT, Global, Auto Alliance, CBD, EDF, IPI, CARB, and Honda all make this argument. CARB

¹⁶⁸⁸ EDF, Appendix B, NHTSA-2018-0067-12108, at 51.

¹⁶⁸⁹ IPI, Policy Integrity Comments: NHTSA Final- Appendix, NHTSA-2018-0067-12213, at 61.

¹⁶⁹⁰ EDF, Appendix B, NHTSA-2018-0067-12108, at 54.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

makes the following statement suggesting that even a larger fleet size should not increase aggregate demand for VMT (again, not including rebound miles):

A change in the overall fleet size due to the Augural standards might not in and of itself be problematic, as long as the VMT schedules are adjusted to account for overall travel activity that is distributed over a larger number of vehicles. However, the As-Received version of the [scrappage] model does not adjust VMT schedules, with the result that the additional unscrapped vehicles inflate total VMT proportionally.¹⁶⁹¹

The agencies agree that the aggregate demand for VMT should be roughly constant across alternatives, and stated this in the NPRM, where the differences in non-rebound VMT were on the order of 0.4%.

NERA's modelling efforts found similar small decreases in VMT in regulatory alternatives where the standards are relaxed. The Alliance stated:

Under all three scenarios, vehicle miles traveled ("VMT") decreases relative to the augural standards. This is due primarily to rebound effects. Because NERA was only examining vehicles through MY 2029, the difference in VMT between the alternatives and the augural standards decreases over time, since fewer of the MY 2029 and earlier vehicles are on the road in those later years.¹⁶⁹²

NERA's model used similar assumptions as the NPRM analysis and, like the NPRM results, the NERA model results suggest that it is plausible that total VMT could decline under less stringent standards. A key assumption common to NERA's model and the NPRM analysis is that the VMT schedules are constant under all scrappage rates. However, as discussed in Section I.A.1.a)(1)(b)(iv)(c), this can potentially overestimate total VMT in the augural case, where vehicles that were marginally scrapped in the proposal are kept on the road.

Presumably, vehicles that are scrapped in the proposal, but not in the augural, are in more disrepair than others in the same age cohort. As a result, these vehicles would on average be driven less, bringing down the average usage of the entire age cohort. This effect could alter the relative size of total VMT under the regulatory alternatives, as Honda notes in the following comment:

According to our calculations, if the impact of lowering the average cohort's utility is even 0.2% the augural standards would become *safer* than the preferred alternative. We believe that the agencies should consider VMT behavior change as part of an effort to mature and refine the scrappage model.¹⁶⁹³

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

As Honda suggests, a relatively small reduction in the average VMT schedules for the more stringent regulatory alternatives could result in a change in the direction of the safety impact. This shows the importance of investigating the linkage between usage and scrappage rates, but also shows that small changes to the total VMT assumptions can have meaningful impacts on the predicted effects of the analysis. Other commenters make similar points.

As noted above, the difference in total non-rebound VMT in the NPRM analysis was only 0.4%. However, CBD notes that this relatively small change in VMT across the alternatives in a single year can result in a large number of cumulative additional miles in more stringent regulatory alternatives:

While 0.4% sounds small, when the scrappage model's effect it is multiplied by all the VMT that NHTSA includes in its analysis, spanning decades, it becomes highly significant—at least 692 billion additional VMT under the CAFE standards and 894 billion under the CO₂ program, both relative to the preferred alternative.¹⁶⁹⁴

Since VMT is related to many of the costs and benefits of the program, differences in cumulative VMT of this magnitude can have meaningful impacts on the incremental net benefit analysis. This point was implied by comments from CBD, EDF, NCAT, EAO, and in a paper published by academics after the issuance of the NPRM.¹⁶⁹⁵ For this reason, the agencies have opted to constrain total non-rebound VMT across regulatory alternatives.

Such a constraint was suggested by EDF, IPI and other commenters. EDF states the following:

A sophisticated model is not needed to correct this problem. One only needs to adjust the VMT added by the “scrappage model” so that it matches the VMT lost by the sales response model. Put another way, used vehicles would be used to the same extent as new vehicles since they meet the identical demand (possibly minus a rebound effect).¹⁶⁹⁶

EDF goes on to suggest some potential issues with implementing this constraint:

Even this adjustment would still be in favor of the proposal, as it assumes that all the VMT lost from fewer new vehicle sales would be replaced by used vehicle VMT. This assumes that travel is inelastic. This is clearly not the case given NHTSA's position on the rebound effect. NHTSA must first justify the used vehicle response to any change in new vehicle sales. Then, in the unlikely event that this can be done, NHTSA must link the scrappage model to the sales response model to ensure that the combination of the

¹⁶⁹⁴ CBD, Appendix A, NHTSA-2018-0067-12000, at 180.

¹⁶⁹⁵ Bento, Antonio M., et al. “Flawed Analyses of U.S. Auto Fuel Economy Standards.” *Science*, vol. 362, no. 6419, 2018, pp. 1119–1121., doi:10.1126/science.aav1458.

¹⁶⁹⁶ EDF, Appendix B, NHTSA-2018-0067-12108, at 49.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

two models does not increase VMT in any calendar year (and probably show a decrease, as the overall cost of driving will have increased).¹⁶⁹⁷

The agencies disagree that lost new vehicle sales would impact the VMT of the new vehicles that are sold. The agencies do, however, as EDF notes, adjust the VMT of new vehicles to consider changes in the cost per mile of travel. In fact, when fuel prices increase, the agencies assume that owners of all existing vehicles drive less; the reduction will be greater when the vehicles on the road are less efficient, which seems consistent with what EDF suggests in the last sentence above. The agencies have justified the scrappage effect throughout this discussion, above.

EDF identifies another reason the agencies think a constraint on total VMT is reasonable for purpose of the final rule analysis. The scrappage, sales, and VMT models each have a certain amount of uncertainty associated with it (the uncertainty of the scrappage model is discussed in Section I.A.1.a)(1)(b)(i)(a)), so that when the three models are combined, the uncertainty is compounded. EDF characterizes these results as being inconsistent with economic theory in the comment below:

We are not aware of any economic arguments which would support such an increase. All that can be said is that NHTSA put data from a variety of sources through a statistical regression and never bothered to see if the results were reasonable or consistent with its own economic theory.¹⁶⁹⁸

The NPRM analysis discussed total fleet size and VMT at length; the agencies noted that the fleet was 1.5% bigger for the augural standard than the proposal, resulting in 0.4% additional non-rebound VMT in CY2050.¹⁶⁹⁹ However, given the amount of uncertainty around each of the models, and considering that differences in total VMT can have meaningful impacts on the cost benefit analysis, the agencies are conservatively assuming for the final rule analysis that non-rebound VMT is constant, to constrain the outputs derived from the combination of the three models.

(v) Comments on the Evaluation of Associated Costs and Benefits

(a) Presentation and Valuation of Non-Rebound Miles

IPI and EDF argued that it was inconsistent to exclude the costs and benefits of additional rebound driving but include them for the sales and scrappage effect. For example, EDF stated:

¹⁶⁹⁷ EDF, Appendix B, NHTSA-2018-0067-12108, at 49.

¹⁶⁹⁸ EDF, Appendix B, NHTSA-2018-0067-12108, at 57.

¹⁶⁹⁹ FR, Vol 83, No. 165, August 24, 2018, p.43099.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

[W]hen a vehicle is driven an additional mile, there is value associated with that travel. NHTSA completely ignores the value of any additional travel which occurs due to reduced scrappage. Including this value would not be an adequate surrogate for the additional repair costs required to keep older vehicles on the road. Just as NHTSA is now recognizing that rebound VMT is due to drivers' express decision to drive more, any driving of older vehicles in lieu of new vehicles is due to the same choice. To treat these identical choices in 180 degree different manners is of course manifestly arbitrary.¹⁷⁰⁰

The agencies agree that there is value associated with additional miles driven. The NPRM did not directly attribute costs for the loss of additional miles in the scrappage analysis when the fleet size shrank. The final rule analysis addresses this issue by holding non-rebound total VMT constant across regulatory alternatives. However, contrary to what EDF suggests above, the cost of additional maintenance and repair for otherwise-scrapped vehicles are not directly related to the additional miles. The cost of additional maintenance and repair is incurred because the value of used vehicles has increased. The increase in value of the used vehicles should at least offset the maintenance and repair costs. Any remaining increase in value is offset by lost utility from consumers buying fewer new vehicles.

Holding aggregate non-rebound VMT constant across alternatives addresses IPI's and EDF's concerns that additional miles due to a larger fleet size were not adequately valued. Additional fatalities due to shifting the distribution of those miles towards less safe vehicles should still count in the cost benefit analysis. The marginal utility of a mile driven in a newer vehicle is on average higher than that driven in an older vehicle. The regulation is responsible for the shift in the distribution of miles driven at each vehicle age. Including the additional safety risks and fuel costs accrued from more miles being driven by older vehicles accounts for at least a part of the reduction in the marginal utility of the average mile under more stringent standards.

(b) Increase in Maintenance and Repair
Costs and Used Vehicle Values

EDF and others also commented that the agencies should include the value of additional maintenance and repair costs and the increase in value for used vehicles explicitly in the cost and benefit analysis. They state the following:

"It is important to note that NHTSA fails to account for three large economic impacts occurring during this process.

1. The increase in value of the entire used vehicle fleet from 2017-2050. This is a windfall gain for all current vehicle owners that is completely ignored;
2. The cost of repairing and maintaining the older vehicles which are no longer scrapped,

¹⁷⁰⁰ EDF, Appendix B, NHTSA-2018-0067-12108, at 58.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

3. The value of the additional driving that these vehicles provide.

NHTSA only counts the costs related to the additional driving performed by the non-scrapped vehicles. Again, NHTSA's decision to only include this cost maximizes monetary costs related to the current standards and minimizes those related to the proposal."¹⁷⁰¹

As discussed above, in Section **Error! Reference source not found.**(b)(5)(a), the agencies hold the non-rebound fleetwide VMT constant to an exogenous projection of aggregate VMT. This addresses EDF's third concern, above. Without a model of the used vehicle market it is impossible for the agencies to estimate the value increase of used vehicles due to a substitution towards used vehicles when new vehicle prices increase. However, the maintenance and repair costs should be less than or equal to the increase in vehicle value (or the current owner would not pay to maintain the vehicle). Not including the additional maintenance and repair costs should at least partially offset not including the increase in the value of used vehicles. The remaining increase in vehicle value should be a transfer between the seller and buyer of a used vehicle so that it should be both a cost and benefit exactly offsetting. Thus, the total costs and benefits are understated by the same amount, and including them should not affect the reported net benefits of the rule.

(c) Scrappage Effects from MY2030 and Beyond

The NPRM analysis considered cost per mile as a continuous variable, and new vehicle prices in discrete levels. This means that persistently higher new vehicle prices in more stringent standards would continue to suppress the scrappage rate of existing vehicles. It also means that higher fuel economies in more stringent scenarios would continue to affect the scrappage rates as well. EDF noted that the cost and benefit accounting that considered the costs and benefits accruing to the remaining lifetimes of MYs 1977-2029 included some of the costs of the scrappage effect due to the higher prices of MYs beyond 2030, but did not include the benefits of the reduced fuel economy for these MYs. EDF proposed that the agencies consider a CY analysis instead of the model year presented in the NPRM:

[A] 2017-50 CY analysis would include the operation of 2017-2029 MY vehicles through CY 2050. This would include the any scrappage effects on these vehicles through 2050, consistent with the inclusion of new 2050 MY vehicles in the analysis. Some of the operation of all the 2017-2029 MY vehicles would be excluded from the analysis, as these vehicles are not assumed to be scrapped in the Volpe Model until CY 2052-2068. Such an analysis would include the benefits over the clear majority of the operation of

¹⁷⁰¹ EDF, Appendix B, NHTSA-2018-0067-12108, at 50.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

2017-2029 MY vehicles compared to both the shorter calendar year analysis and NHTSA's 1977-2029 MY analysis. It would also include the scrappage effects caused by 2017-2050 MY vehicles through CY 2050. Any scrappage effects would be applied to 2030-2050 MY vehicles, as well as 2017-2029 MY vehicles.¹⁷⁰²

However, as the commenter also notes, a CY analysis would exclude some of the lifetime costs and benefits of improving the fuel economy of MYs impacted by the rule (MYs 2017-2029). For this reason, the agencies do not think that a CY analysis should supplant the MY perspective shown in the NPRM.

EDF presents an alternative to switching to a CY analysis which would exclude the scrappage effects due to differences in the prices and fuel efficiencies of MYs not included in the cost benefit analysis (MY 2030 and beyond):

An alternative that keeps the model year structure of NHTSA's 1977-2029 MY analysis would be to modify it by removing any scrappage effects occurring in 2030 CY and beyond. This analysis would still have the disadvantage of barely including any vehicles which reflect full compliance with the current and proposed standards in 2025. However, it would at least remove the primary problem with NHTSA's current MY analysis. The impact of including the scrappage effects caused by 2030 and later MY vehicles simply and straightforwardly increases the VMT of used vehicles under the current standards.¹⁷⁰³

The agencies note that previous analyses have not considered the costs and benefits of MYs beyond those which could be a response to the change in the considered set of standards. Part of the reason for this was that future standards are unknown, and without existing standards in place, manufacturers may choose to shift application of fuel saving technologies to increases in vehicle performance or safety. The CAFE model does not currently simulate such actions, so that including MYs too far into the future may overstate the costs and benefits of the rule.

While the agencies disagree that excluding cost and benefits of MYs beyond 2030 is an issue for the cost benefit analysis, we agree that allowing persistently higher prices and fuel economies of future MYs to impact the scrappage of the on-road fleet but not considering the costs and benefits of those MYs is inconsistent. However, changes to the scrappage model mitigate this issue. As noted in Section I.A.1.a)(1)(b)(i)(c) and I.A.1.a)(1)(b)(ii), updates to the time series strategy and the way that new vehicle fuel economy is modelled in the FRM scrappage model change the form of how new vehicle prices and fuel economy enter the equation. First, addressing the autocorrelation by taking the first difference of variables with first order integration instead of including lags of the dependent variables means that cost per mile variables and new vehicle prices are captured as changes rather than in levels. This means that constant, but higher, new vehicle prices in the augural standards will not continue to impact the scrappage rates of existing vehicles. More specifically, higher prices of MYs 2030 and

¹⁷⁰² EDF, Appendix B, NHTSA-2018-0067-12108, at 22.

¹⁷⁰³ EDF, Appendix B, NHTSA-2018-0067-12108, at 23.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

beyond in the augural case will no longer result in lower scrappage rates for prior MYs. Further, since new vehicle cost per mile is no longer explicitly included, but rather the amount of fuel savings consumers of new vehicles value at the time of purchase is excluded from the new vehicle prices series, differences in new vehicle fuel economies for MYs beyond 2029 will no longer impact the scrappage rates of earlier MYs. This naturally takes care of the concern raised by several commenters that the accounting for costs and benefits due to changes in MYs 2030 and beyond was inconsistent due to the scrappage model.

(c) *Estimation of the FRM Scrappage Models*

(i) Framing Dynamic Scrappage Models in the Literature

(a) How Fuel Economy Standards Impact Vehicle Scrappage

As noted above, any increase in price (net of the portion of reduced fuel savings valued by consumers) will increase the expected life of used vehicles and reduce the number of new vehicles entering the fleet (the Gruenspecht effect). In this way, increased fuel economy standards slow the turnover of the fleet and the entrance of any regulated attributes tied only to new vehicles. Gruenspecht tested his hypothesis in his 1981 dissertation using new vehicle price and other determinants of used car prices as a reduced form to approximate used car scrappage in response to increasing fuel economy standards.

Greenspan and Cohen (1996) offer additional foundations from which to think about vehicle stock and scrappage. Their work identifies two types of scrappage: engineering scrappage and cyclical scrappage. Engineering scrappage represents the physical wear on vehicles which results in their being scrapped. Cyclical scrappage represents the effects of macroeconomic conditions on the relative value of new and used vehicles—under economic growth the demand for new vehicles increases and the value of used vehicles declines, resulting in increased scrappage. In addition to allowing new vehicle prices to affect cyclical vehicle scrappage à la the Gruenspecht effect, Greenspan and Cohen also note that engineering scrappage seems to increase where EPA vehicular-criteria pollutant emissions standards also increase; as more costs go towards compliance technologies, it becomes more expensive to maintain and repair more complicated parts, and scrappage increases. In this way, Greenspan and Cohen identify two ways that fuel economy standards could affect vehicle scrappage: 1) through increasing new vehicle prices, thereby increasing used vehicle prices, and finally, reducing on-road vehicle scrappage, and 2) by shifting resources towards fuel-saving technologies—potentially reducing the durability of new vehicles by making them more complex.

(b) Aggregate vs. Atomic Data Sources in the Literature

One important distinction in literature on vehicle scrappage is between those that use atomic vehicle data (data following specific individual vehicles), and those that use some level of

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

aggregated data (data that counts the total number of vehicles of a given type). The decision to scrap a vehicle is made on an individual vehicle basis, and relates to the cost of maintaining a vehicle, and the value of the vehicle both on the used car market, and as scrap metal. Generally, a used car owner will decide to scrap a vehicle when the value of the vehicle is less than the value of the vehicle as scrap metal, plus the cost to maintain or repair the vehicle. In other words, the owner gets more value from scrapping the vehicle than continuing to drive it, or from selling it.

Recent work is able to model scrappage as an atomic decision due to the availability of a large database of used vehicle transactions. Work by authors including Busse, Knittel, and Zettelmeyer (2013), Saltee, West, and Fan (2010), Alcott and Wozny (2013), and Li, Timmins, and von Haefen (2009) consider the impact of changes in gasoline prices on used vehicle values and scrappage rates. In turn, they consider the impact of an increase in used vehicle values on the scrappage rate of those vehicles. They find that increases in gasoline prices result in a reduction in the scrappage rate of the most fuel efficient vehicles and an increase in the scrappage rate of the least fuel efficient vehicles. This has important implications for the validity of the average fuel economy values linked to model years, and assumed to be constant over the life of that model year fleet within this study. Future iterations of such studies could further investigate the relationship between fuel economy, vehicle usage, and scrappage, as noted in other places in this discussion.

While the decision to scrap a vehicle is made atomically, the data available to NHTSA on scrappage rates and variables that influence these scrappage rates are aggregate measures. This influences the best available methods to measure the impacts of new vehicle prices on existing vehicle scrappage. The result is that this study models aggregate trends in vehicle scrappage, and not the atomic decisions that make up these trends. Many other works within the literature use the same data source and general scrappage construct, including those by Walker (1968), Park (1977), Greene and Chen (1981), Gruenspecht (1981), Gruenspecht (1982), Feeney and Cardebring (1988), Greenspan and Cohen (1996), Jacobsen and van Benthem (2015), and Bento, Roth, and Zhuo (2016). These works all use aggregate vehicle registration data as the source to compute vehicle scrappage.

Walker (1968) and Bento, Roth and Zhuo (2016) use aggregate data directly to compute the elasticity of scrappage from measures of used vehicle prices. Walker (1968) uses the ratio of used vehicle Consumer Price Index (CPI) to repair and maintenance CPI. Bento, Roth, and Zhuo (2016) use used vehicle prices directly. While the direct measurement of the elasticity of scrappage is preferable in a theoretical sense, the CAFE model does not predict future values of used vehicles, only future prices of new vehicles. For this reason, any model compatible with the current CAFE model must estimate a reduced form similar to Park (1977), Gruenspecht (1981), and Greenspan and Cohen (1996), who use some form of new vehicle prices or the ratio of new vehicle prices to maintenance and repair prices to impute some measure of the effect of new vehicle prices on vehicle scrappage.

(c) Historical Trends in Vehicle Durability

Waker (1968), Park (1977), Feeney and Cardebring (1988), Hamilton and Macauley (1999), and Bento, Ruth, and Zhuo (2016) all note that vehicles change in durability over time. Walker (1968) simply notes a significant distinction in expected vehicle lifetimes pre- and post-World War I. Park (1977) discusses a ‘durability factor’ set by the producer for each year, so that different vintages and makes will have varying expected lifecycles. Feeney and Cardebring (1988) show that durability of vehicles appears to have generally increased over time both in the U.S. and Swedish fleets using registration data from each country. They also note that the changes in median lifetime between the Swedish and U.S. fleet track well, with a 1.5-year lag in the U.S. fleet. This lag is likely due to variation in how the data is collected—the Swedish vehicle registration requires a title to unregister a vehicle, and therefore gets immediate responses, where the U.S. vehicle registration requires re-registration which creates a lag in reporting further discussed in Section I.A.1.a)(1)(c)(ii)(b).

Hamilton and Macauley (1999) argue for a clear distinction between embodied versus disembodied impacts on vehicle longevity. They define embodied impacts as inherent durability similar to Park’s producer supplied ‘durability factor’ and Greenspan’s ‘engineering scrappage’ and disembodied effects as those which are environmental, not unlike Greenspan and Cohen’s ‘cyclical scrappage.’ They use calendar year and vintage dummy variables to isolate the effects—concluding that the environmental factors are greater than any pre-defined ‘durability factor.’ Some of their results could be due to some inflexibility of assuming model year coefficients are constant over the life of a vehicle, and also some correlation between the observed life of the later model years of their sample and the ‘stagflation’¹⁷⁰⁴ of the 1970’s. Bento, Ruth, and Zhuo (2016) find that the average vehicle lifetime has increased 27 percent from 1969 to 2014 by sub-setting their data into three model year cohorts. To implement these findings in the scrappage model incorporated into the CAFE model, this study takes pains to estimate the effect of durability changes in such a way that the historical durability trend can be projected into the future; for this reason, the agencies include a continuous ‘durability’ factor as a function of model year vintage.

(ii) Polk/IHS Registration Data

As in the NPRM, NHTSA uses proprietary data on the registered vehicle population from IHS/Polk for the scrappage models. IHS/Polk has annual snapshots of registered vehicles counts beginning in calendar year (CY) 1975 and continuing until CY2017. Notably, the data collection procedure changed in CY2002, which requires some special consideration (discussed below). The data includes the following regulatory classes as defined by NHTSA: passenger cars, light trucks (classes 1 and 2a), and medium and heavy-duty trucks (classes 2b and 3). Polk separates these vehicles into another classification scheme: cars and trucks. Under their schema, pickups, vans, and SUVs are treated as trucks, and all other body styles are included as cars. In order to

¹⁷⁰⁴ Continued high inflation combined with high unemployment and slow economic growth.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

build scrappage models to support the model year (MY) 2021-2026 light duty vehicle (LDV) standards, it was important to separate these vehicle types in a way compatible with the existing CAFE model.

(a) Choice of Aggregation Level: Body style

Two compatible methods existed by which the agencies could aggregate scrappage rates: by regulatory class or by body style. Since, for CAFE purposes, vans/SUVs are sometimes classified as passenger cars and sometimes as light trucks (depending upon vehicle-specific attributes) and there was no simple way to reclassify some SUVs as passenger cars within the Polk dataset, the agencies chose to aggregate survival schedules by body style. This approach is also preferable because it is consistent with the level of aggregation of the VMT schedules. Since usage and scrappage rates are not independent of each other, if average usage rates are meaningfully different at the level of body style, it is likely that scrappage rates are as well.

Once stratified into body style level buckets, the data can be aggregated into population counts by vintage and age. These counts represent the population of vehicles of a given body style and vintage in each calendar year. The difference between the counts of a given vintage and vehicle type from one calendar year to the next is assumed to represent the number of vehicles of that vintage and type scrapped in each year.

(b) Greenspan and Cohen Correction

One issue with using snapshots of registration databases as the basis for computing scrappage rates is that vehicles are not removed from registration databases until the last valid registration expires—for example, if registrations are valid for a year, vehicles will still appear to be registered in the calendar year in which they are scrapped. To correct for the scrappage that occurs during a calendar year, a similar correction as that in Greenspan and Cohen (1996) is applied to the Polk dataset. It is assumed that the real on-road count of vehicles of a given MY registered in a given CY is best represented by the Polk count of the vehicles of that model year in the succeeding calendar year ($Polk_{CY+1}$). For example, the vehicles scrapped between CY2000 and CY2001 will still remain in the Polk snapshot from CY2000 ($Polk_{CY2000}$), as they will have been registered at some point in that calendar year, and therefore exist in the database. Using a simplifying assumption that all States have annual registration requirements,¹⁷⁰⁵ vehicles scrapped between July 1st, 1999 and July 1st, 2000 will not have renewed registration between July 1st, 2000 and July 1st, 2001, and will not show up in $Polk_{CY2001}$. The vehicles scrapped

¹⁷⁰⁵In future analysis, it may be possible to work with State-level information and incorporate State-specific registration requirements in the calculation of scrappage, but this correction is beyond the initial scope of this rulemaking analysis. Such an approach would be extraordinarily complicated as States can have very different registration schemes, and, further, the approach would also require estimates of the interstate and international migration of registered vehicles.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

during CY2000 are therefore represented by the difference in count from the CY2000 and CY2001 Polk datasets: $Polk_{CY2001} - Polk_{CY2000}$.

For new vehicles (vehicles where MY is greater than or equal to CY), the count of vehicles will be smaller than the count in the following year—not all of the model year cohort will have been sold and registered. For these new model years, Greenspan and Cohen assume that the Polk counts will capture all vehicles which were present in the given calendar year and that approximately one percent of those vehicles will be scrapped during the year. Importantly, this analysis begins modeling the scrappage of a given model year cohort in: $CY = MY + 2$,¹⁷⁰⁶ so that the adjustment to new vehicles is not relevant in the modeling because it only considers scrappage after the point where the on-road count of a given MY vintage has reached its maximum.

(c) Polk Data Collection Changes

Prior to calendar year 2002, Polk vehicle registration data was collected as a single snapshot on July 1st of every calendar year. All vehicles that are in the registration database at that date are included in the dataset. For calendar years 2002 and later, Polk changed the timing of the data collection process to December 31st of the calendar year. In addition to changing the timing of the data collection, Polk updated the process to a rolling sample. That is, they consider information from other data sources to remove vehicles from the database that have been totaled in crashes before December 31st, but may still be active in State registration records.

The switch to a partially rolling dataset will mean that some of the vehicles scrapped in a calendar year will not appear in the dataset and their scrappage will wrongly be attributed to the year prior to when the vehicle is scrapped. While this is less than ideal, these records represent only some of the vehicles scrapped during crashes and scrappage rates due to crashes should be relatively constant over the 2001 to 2002-time period. For these reasons, the agencies expect the potential bias from the switch to a partially rolling dataset to be limited. Thus, the Greenspan and Cohen adjustment applied does not change for the dataset compiled from Polk's new collection procedures. As indicated in [Figure II-28](#)~~Figure VI-53~~, the scrappage counts computed from the old Polk snapshot series represent vehicles scrapped between July 1st of a given calendar year and the succeeding July 1st, and is computed for CY1976-2000. The new Polk snapshot series represents vehicles scrapped between December 31st of a given calendar year and the succeeding calendar year, and is computed for CY2002-2016.

¹⁷⁰⁶ Calculating scrappage could begin at $CY=MY+1$, as for most model year the vast majority of the fleet will have been sold by July 1st of the succeeding CY, but for some exceptional model years, the maximum count of vehicles for a vintage in the Polk data set occurs at age 2.

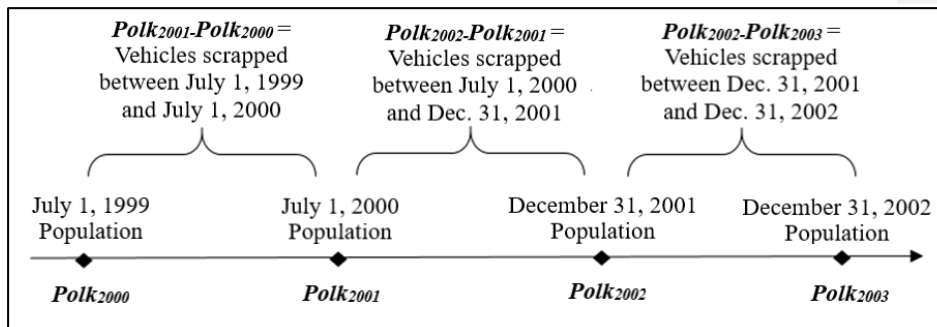

Figure II-2859 - Visualization of Greenspan-Cohen Adjustment and Polk Data Collection Change

There is a discontinuity between the old and new methods so that the computed scrappage for calendar year 2001 represents the difference between the vehicle count reported in $Polk_{CY2002}$ and $Polk_{CY2001}$. $Polk_{CY2001}$ represents all vehicles on the road as of July 1st, 2000, and $Polk_{CY2002}$ represents all vehicles on the road as of December 31, 2001. For this one timespan, the scrappage will represent vehicles scrapped over a 17-month time period, rather than a year. For this reason, the CY2001 scrappage data point is dropped, and because of the difference in the time period of vehicles scrapped under the old and new collection schemes, an indicator for scrappage measured before and after CY2001 was considered; however, this indicator is not statistically significant, and is dropped from the preferred model.

(d) Updated FRM Dataset

As noted in section II.A.1, some commenters expressed concern about the inability of the scrappage model to predict the scrappage rates of vehicles over age 20. The inability was in large part due to the limited data on the scrappage rates of older vehicles. NHTSA has worked with Polk/IHS to construct some of the historical registration databases using the new methodology for the purposes of other research. As a result, the agency has registration data using *both* Polk collection methods for CY's 2001-2012. Importantly, the old Polk dataset censored data on older vehicles, with CY's 1975-1993 including vehicles ages 0-15 and each successive CY past 1993 adding one additional age to the dataset—so that by 2000 ages 0-22 are included. The new datasets do not censor data on older vehicles, giving these datasets an advantage over the old datasets—for this reason, NHTSA uses as many years of the new data as is available.

The NPRM analysis also used all of the available data using the new methodology at the time of publication (CY's 2005-2015). Since the NPRM was published, NHTSA has gained access to registration data using Polk's new methodology for CY's 2002-2005 and CY's 2016-2017. [Table II-54](#)[Table VI-134](#) shows the calendars years of data in the NPRM and the final rule datasets by age, as well as the total number of data points for each age. There are a total of 330 and 420 data points for ages over 15 in the NPRM and final rule datasets, respectively. That

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

represents almost a 30 percent increase in the number of data points for vehicles over 15, and a 50 percent increase in the number of data points for the oldest vehicles considered in the dataset (ages 27-39). This additional data on older vehicles allows the new scrappage models to better predict the survival rates of older vehicles than the NPRM models.

Table II-~~54~~²⁷ - Summary of NPRM vs. Final Rule Datasets by Vehicle Age

Ages	NPRM CYs	Count	Final Rule CYs	Count
0-15	1975-2015	41	1975-2017	43
16	1994-2015	22	1994-2017	24
17	1995-2015	21	1995-2017	23

(e) Models of the Gruenspecht Effect
Used in Other Policy Considerations

This is not the first estimation of the ‘Gruenspecht Effect’ for rulemaking policy considerations. In their Technical Support Document (TSD) for its 2004 proposal to reduce emissions from motor vehicles, CARB outlined how they utilized the CARBITS vehicle transaction choice model in an attempt to capture the effect of increasing new vehicle prices on vehicle replacement rates. They considered data from the National Personal Transportation Survey (NPTS) as a source of revealed preferences and a University of California (UC) study as a source of stated preferences for the purchase and sale of household fleets under different prices and attributes (including fuel economy) of new vehicles.

The transaction choice model represents the addition and deletion of a vehicle from a household fleet within a short period of time as a “replacement” of a vehicle, rather than as two separate actions. CARB’s final data set consists of 790 vehicle replacements, 292 additions, and 213 deletions; they do not include the deletions, but assume any vehicle over 19 years old that is sold is scrapped. This allowed CARB to capture a slowing of vehicle replacement under higher new vehicle prices. That said, because their model does not include deletions, it does not explicitly model vehicle scrappage, but assumes all vehicles aged 20 and older are scrapped rather than resold. CARB calibrated the model so that the overall fleet size is benchmarked to Emissions FACTors (EMFAC) fleet predictions for the starting year; the simulation then produced estimates that match the EMFAC predictions without further calibration.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The CARB study captures the effect on new vehicle prices on the fleet replacement rates, and offers some precedence for including an estimate of the Gruenspecht Effect. However, because vehicles that exited the fleet without replacement were excluded, we do not learn the effect of new vehicle prices on scrappage rates where the scrapped vehicle is not replaced. New and used vehicles are substitutes, and therefore we expect used vehicle prices to increase with new vehicle prices. And because higher used vehicle prices will lower the number of vehicles whose cost of maintenance is higher than their value, we expect the replacements of used vehicles to slow, but we also expect that some vehicles that would have been scrapped without replacement under lower new vehicle prices will now remain on the road because their value will have increased. The agencies' aggregate measures of the Gruenspecht effect includes changes to scrappage rates both from slower replacement rates, and from slower non-replacement scrappage rates.

(f) Car Allowance Rebate System
(‘Cash for Clunkers’)

On June 14, 2009, the Car Allowance Rebate System (CARS) became law, with the intent to stimulate the economy through automobile sales and accelerate the retirement of older, less fuel efficient and less safe vehicles. The program offered a \$3,500 to \$4,500 rebate for vehicles traded-in for the purchase of a new vehicle. Vehicles were subject to several program eligibility criteria: first, the vehicle had to be drivable and continuously registered and insured by the same owner for at least one year; second, the vehicle had to be less than 25 years old; third, the MSRP had to be less than \$45,000; and finally, the new vehicle purchased had to be more efficient than the trade-in vehicle by a specified margin. The fuel economy improvement requirements by body style for specific rebates are presented in [Table II-55](#)~~Table VI-135~~.

Table II-~~55~~~~128~~ - CARS Fuel Economy Improvement Required for Rebates by Regulatory Class

	\$3,500 Rebate Eligibility	\$4,500 Rebate Eligibility
Passenger Car	4-9 MPG Improvement	10+ MPG Improvement
Light Truck	2-5 MPG Improvement	5+ MPG Improvement

The program was originally budgeted for \$1 billion dollars and to end on November 1, 2009, but that amount was spent far more quickly than expected and the program received an additional \$1.85 billion in funding. Even with that additional funding, the program only lasted through August 25, 2009, expending \$2.85 billion on 678,359 eligible transactions. To ensure that the replaced vehicles did not remain on the road, the vehicles were scrapped at the point of trade-in by destroying the engine. While the program resulted in the replacement of more vehicles and at a faster rate than expected, critics have argued that many of the trade-ins would have happened even if the program had not been in place, so that any economic stimulus to the automobile industry during the crisis cannot be attributable to the CARS program. Further, others have argued that forcing the scrappage of vehicles that could still remain on the road has

negative environmental impacts that could outweigh any environmental benefits of the reduced fuel consumption from the accelerated retirement of these less efficient vehicles.

Li, Linn, and Spiller (2010) use Canada as a counterfactual example to identify the portion of CARS trade-ins attributable to the policy, i.e., trade-ins that would not have happened anywhere if the program were not in place. They argue that the Canadian market is largely similar to the U.S. market, in part based upon the fact that 13 to 14 percent of households purchased new vehicles one year pre-recession in both countries. They also argue that the economic crisis affected the Canadian economy in a similar manner as it affected the U.S. economy. While they note that Canada offered a small rebate of \$300 to vehicles traded in during January, 2009, they further note that only 60,000 vehicles were traded in under that program. Using those assumptions, Li, et al., applied a difference-in-difference methodology to isolate the effect of the CARS program on the scrappage of eligible vehicles. Li, et al., found a significant increase in the scrappage only for eligible U.S. vehicles, suggesting they isolated the effect of the policy. They conclude that of the 678,359 trade-ins made under the program, 370,000 of those would not have happened during July and August 2009. They conclude that the CARS program reduced gasoline consumption by 0.9-2.9 billion gallons, at \$0.89-\$2.80 per gallon saved.

The agencies find the evidence from Li, et al., persuasive toward the inclusion of a control for the CARS program during calendar year 2009. The importance is discussed further both in the data section, Section I.A.1.a)(1)(c)(ii), which provides more evidence for the effect of the CARS program, and in the model specifications Section I.A.1.a)(1)(c)(iii), which describes the control used for the effect of the program. This ensures that the measurements of other determining factors are not biased by the exceptional scrappage observed in calendar year 2009.

(iii) Updated Final Rule Modeling

The agencies contemplated all of the comments and suggestions made by commenters and, in response, have made several changes to final rule's model. First, we changed the time-series strategy used in the model, as discussed in Section I.A.1.a)(1)(c)(iii)(a). This change allows the agencies to simplify the models significantly, addressing commenters' concerns about potential overfitting of the model and difficulty of interpreting individual coefficient values (discussed in Section I.A.1.a)(1)(b)(i)). Second, the agencies changed the modeling of the durability effect as discussed in Section I.A.1.a)(1)(c)(iii)(c); this change reduces the reliance on the decay function and has the added benefit of addressing concerns about overfitting and out-of-sample projections discussed in Section I.A.1.a)(1)(b)(i). Third, a portion of anticipated fuel savings from increased fuel economy are netted from new vehicle prices—meaning consumers are now assumed to value fuel economy at the time of purchase to a certain extent—as discussed in Section I.A.1.a)(1)(c)(iii)(d). This change is in response to comments discussed in Section I.A.1.a)(1)(b)(ii) and addresses inconsistent treatment of consumer valuation within the NPRM's analysis. Finally, we consider the inclusion of additional or alternative variables in the scrappage model in response to comments discussed in Section I.A.1.a)(1)(b)(iii). After extensive testing, the agencies concluded that these additional variables do not improve the model fits or would introduce autocorrelation in the error structures (see Sections I.A.1.a)(1)(c)(iii)(e) and I.A.1.a)(1)(c)(iii)(f) for further discussion). As such, the agencies rejected the additional terms

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

suggested by commenters. Input from commenters was used to simplify the scrappage model, make it more consistent with modeling of new vehicle prices elsewhere in the analysis, and improve its predictions for the instantaneous scrappage rates of vehicles beyond age 20.

(a) Changes to the Time Series Strategy

As discussed in Section (b)(i)(c), the agencies reconsidered the time series strategy for the final rule in response to comments. The first step in doing so is to test the time series properties of the dependent and independent variables. The agencies use the Augmented Dickey-Fuller (ADF) unit root test implemented in the ‘CADFtest’ R package to test for stationarity.¹⁷⁰⁷ The agencies find that the logistic scrappage rate is I(0), or stationary in levels. Since the dependent variable is stationary, there is no long-term trend in scrappage rates to capture. Lags of dependent variables need not be included, but their stationary forms should be used in the regressions. The following table summarizes the order of integration of each of the considered regressions; the regression forms represent the form of the variable that is included in the considered models.¹⁷⁰⁸ All the variables considered are either I(0) or I(1), meaning that they should be run in either levels or first differences, respectively. This significantly simplifies the regressions. Two unintended, positive outcomes of this change in time series strategy are that the coefficients on variables are easier to interpret and the models are less likely to be overfit. In this way, the shift to address concerns about the time series strategy (discussed in Section (b)(i)(c)) also addresses commenter concerns outlined in Section (b)(i)(a).

Table II-~~56429~~ - Summary of Order of Integration of Considered Scrappage Variables

Scrappage Factor	Possible Measure(s)	Integration Order(s)	Regression Form(s)
Logistic scrappage rate	LHS variable: measure of scrappage rates	I(0)	Levels
Age	Age defined by the Greenspan/Cohen adj.	N/A	Levels
Usage	Not considered (unreliable VMT estimates)	N/A	N/A
Model year	Model year as defined from dataset	N/A	Levels

Scrappage Factor	Possible Measure(s)	Integration Order(s)	Regression Form(s)
Business cycle indicators	GDP growth rates, unemployment rate, per-capita personal incomes, real interest rates	I(0), I(1), I(1), I(1)	Levels, difference, difference, difference
Prices of purchase/use	Used vehicle prices (endogenous--omitted), fuel prices, cost-per-mile	N/A, I(1), I(1)	N/A, difference, difference
Maintenance/repair costs	Maintenance/repair CPI	I(1)	Difference
Value as scrap	Iron/steel scrap CPI	I(1)	Difference
Prices/quantity supply of substitutes	Nada prices, quantity new vehicles sold	I(1), I(1)	Difference, difference
Control for quality	Used to new horsepower to weight ratio, used fuel consumption	I(0), I(1)	Levels, difference

(b) Final Rule Preferred and Sensitivity Specifications

After consideration of comments on, and subsequent peer review of, the NPRM analysis, the agencies updated the scrappage model specifications for the final rule. Section I.A.1.a)(1)(c)(iii)(a) through I.A.1.a)(1)(c)(iii)(f) discuss other considered specifications and variables. The equation below represents the final form of the scrappage equation included in the central and sensitivity analysis:

$$\ln\left(\frac{S_{MY,CY}}{1 - S_{MY,CY}}\right) = \beta_0 * Age_{MY,CY} + \beta_1 * Age^2_{MY,CY} + \beta_2 * Age^3_{MY,CY} +$$

$$Share\ Remaining_{MY,CY} * (\beta_3 + \beta_4 * Age_{MY,CY}) +$$

$$Diff(New\ Price - FS)_{CY} * (\beta_5 + \beta_6 * Age_{MY,CY} + \beta_7 * Age^2_{MY,CY} + \beta_8 * Age^3_{MY,CY}) +$$

$$\beta_9 * Diff(Fuel\ Price)_{CY} + \beta_{10} * Diff(CP100M_{MY})_{CY} + \beta_{11} * GDP\ Growth_{CY} +$$

$$(\beta_{12} + \beta_{13} * [Age \geq 25]) * CY2009 + (\beta_{14} + \beta_{15} * [Age \geq 25]) * CY2010 + FE_{MY}$$

Here, “S” represents the instantaneous scrappage rate in a period, so that the dependent variable is the logit form of the scrappage rates. Logit models ensure that predicted values are bounded—in this case between zero and one. It is not possible to scrap more than all the remaining vehicles, nor fewer than zero percent of them, which is illustrated in the graph below:

Figure II-2960 – Example Logit Curve

Solving for instantaneous scrappage yields the following:

$$S = \frac{e^{\sum \beta_i X_i}}{1 + e^{\sum \beta_i X_i}}$$

In the equation above, $\sum \beta_i X_i$ represents the right-hand side of the above model specification. Within the right-hand side of the equation, *Age* represents the age of the model year cohort in a specific calendar year, defined by the Greenspan and Cohen adjustment discussed in Section I.A.1.a)(1)(c)(ii)(b). The coefficient on the cubic age term is assumed to be zero for the van/SUV and pickup specifications as this term is not necessary to capture the general scrappage trend for these body styles. *Share Remaining* represents the share of the original cohort remaining at the start of the period. These two components represent the engineering portion of scrappage—the inherent durability of a model year and the natural life cycle of how vehicles scrap out of a model year cohort as the cohort increases with age. The determination of these specific forms is discussed in detail in Section I.A.1.a)(1)(c)(iii)(g).

New Price - FS represents the average price of new vehicles minus 30 months of fuel savings for all body styles. The central analysis assumes the coefficient on the age interactions for this term are zero for all body styles, but a sensitivity case allows the elasticity of scrappage to vary with age. *Fuel Price* represents the real fuel prices, weighted by fuel share of the model year cohort being scrapped. *CPI100M* represents the cost per 100 miles of travel for the specific body style of the model year cohort being scrapped under the current period fuel prices and using fuel shares for that model year cohort. These measures capture the response of scrappage rates to new vehicle prices, fuel savings, and to changes in fuel prices that make the used model year cohort more or less expensive to operate. Because these measures are all I(1), as discussed above in 0, the first difference of all of these variables is used in modelling. The other specific modelling considerations that resulted in this form of modelling the new and used vehicles markets are discussed in Sections I.A.1.a)(1)(c)(iii)(d).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

GDP Growth represents the GDP growth rate for the current period. This captures the cyclical components of the macro-economy. Section I.A.1.a)(1)(c)(iii)(e) discusses how this specific measure was chosen, and what other measures were considered as alternative or additional independent variables.

CY2009 and *CY2010* represent calendar year dummies for 2009 and 2010 when the CARS program was in effect; this controls for the impact of the program. *[Age ≥ 25]* represents an indicator for vehicles 25 years and older. The interaction of the calendar year dummies with this indicator allows for the effect of the CARS program to be different for vehicles under 25 versus vehicles 25 and older. Since only vehicles under 25 were eligible for the program (see the discussion of the program in Section I.A.1.a)(1)(c)(ii)(f)), this flexibility is important to correctly control for the program.

Finally, FE represents a set of model year fixed effects used to control for heterogeneity across different model years. This is related to the durability and engineering scrappage. The NPRM model did not include fixed effects because it fit a parametric relationship to model year as a continuous variable as a way to capture durability. This change in how the durability effect is modelled is discussed further in Section. Further, Section I.A.1.a)(1)(c)(iii)(g) discusses trends in the fixed effects and how these are projected forward within the CAFE model.

(c) Modeling Durability Trends over Time

As noted in the NPRM, the durability of successive model years generally increases over time. However, this trend is not constant with vehicle age—the instantaneous scrappage rate of vehicles is generally lower for later vintages up to a certain age, but increases thereafter so that the final share of vehicles remaining converges to a similar share remaining for historically observed vintages. The NPRM parameterized this trend by using the natural log of the model year as a continuous variable interacted with a polynomial form of the age variable—this predicted an increasing but diminishing trend in vehicle durability for younger ages. The analysis for the final rule makes a change that allows more flexibility in durability trends. Below, we consider the survival and scrappage patterns by body style.

Figure II-30Figure VI-55 to Figure II-32Figure VI-57 shows the survival and scrappage patterns of different vintages with vehicle age for cars, SUVs/vans and pickups, respectively. Cars have the most pronounced durability pattern. Figure II-30Figure VI-55 shows that newer vintages scrap slower at first, but that scrap more heavily so that the final share remaining of cars is more or less constant by age 25 for all vintages.

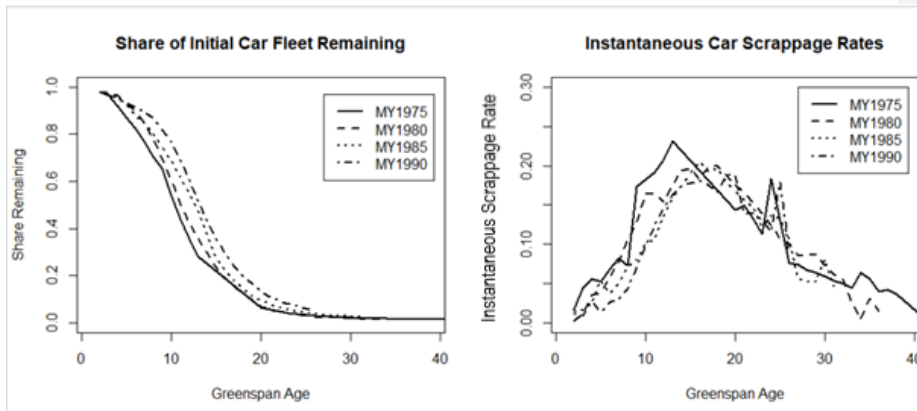

Figure II-3064 - Survival and Scrappage Patterns of Cars by Greenspan Age

SUVs/vans have a less pronounced durability pattern. Model year 1980 actually lives longer than model years 1985 and 1990. This is likely due to a switch of SUVs/vans to be based on car chassis rather than pickup chassis over time. However, through the later model years, the durability trend is more like that of cars. The lack of a continuous trend in durability of SUVs/vans make how this trend is captured particularly important. Below we discuss a change in how the durability trend is modelled for the final rule, which is more flexible than the NPRM model.

Figure II-3162 - Survival of Scrappage Patterns of SUVs/Vans by Greenspan Age

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

There is no clear trend in durability for pickups. Like SUVs/vans, this makes parameterizing by using a form of vintage as a continuous variable problematic. Such a parametric form does not allow for each model year to have its own durability pattern.

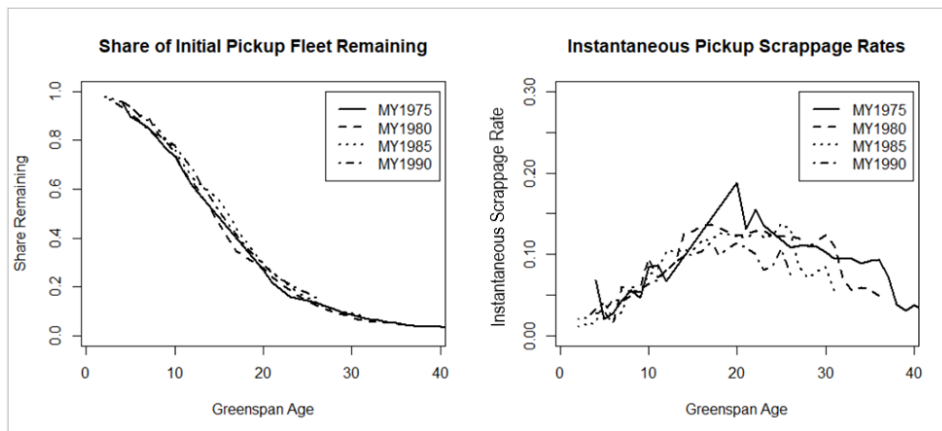

Figure II-3263 - Survival and Scrappage Patterns of Pickups by Greenspan Age

As noted above, the NPRM model used the natural log of model year as a continuous variable interacted with age to capture an increasing but diminishing trend of vehicle durability for the younger ages. However, enforcing a parametric form on a continuous model year excluded the possibility of including model year specific fixed effects and required that durability have a parametric trend with successive vintages. As seen above, SUVs/vans and pickups certainly do not follow such a trend, so that this constraint was too restrictive, at least for these body styles. The final rule analysis makes an adjustment that allows for an initial increase in the durability of a model year to persist, while including fixed effects and relaxing the parametric assumption.

Instead of regressing the natural log of the vintage share in the remaining models, shown in

Table II-57

Table VI-137 through Table II-59Table VI-139, we use the share remaining in the previous period as an independent variable. Since the logistic instantaneous scrappage rate is stationary (it is independent of the previous periods' logistic instantaneous scrappage rate), the share remaining should not be endogenous. The share remaining models for the final rule include model year specific fixed effects and project a linear trend in durability by fitting a regression through the fixed effects. This latter part still requires a parametric assumption about durability (discussed in Section I.A.1.a)(1)(c)(iii)(g)), but not while jointly estimating other coefficients. In this way, the other coefficients should not be biased by projecting the durability trend forwards in the implementation of the scrappage regressions within the CAFE model.

As ~~Table II-57~~~~Table VI-137~~ shows, the NPRM specification and both the constant and the quadratic forms of the age interaction with the share remaining variable to capture the durability effect show evidence of autocorrelation. The linear form of the interaction of age and share remaining does not show evidence of autocorrelation and also has the lowest AIC and highest adjusted R-squared. For these reasons, this is the preferred specification of the durability effect. Since the share remaining coefficient is negative and larger than the positive coefficient on the share remaining interacted with age, a cohort that has a higher share remaining at an early age will have a lower instantaneous scrappage rate in this period until a certain age and then a higher scrappage rate after that age. To find the age where the sign of the share remaining coefficient will switch from predicting a lower instantaneous scrappage rate to a higher one, we must take the ratio of the coefficient on the share remaining variable to the share remaining interacted with age—this suggests that at age 19, the sign of the share remaining variable flips. That is, the instantaneous scrappage rate of cars is predicted to be lower if the share remaining is higher until age 18, after which a higher share remaining predicts a higher instantaneous scrappage rate.

As ~~Table II-58~~~~Table VI-138~~ shows, the linear interaction of age and share remaining is the only specification of the durability effect for SUVs/vans that do not show autocorrelation in the error structure. The linear interaction of age and share remaining has the lowest AIC and highest R-squared; for this reason, this is the preferred specification of the durability effect for SUVs/vans. The signs for share remaining and share remaining interacted with age show a similar trend as that to cars. Taking the ratio again of the share remaining to the share remaining interacted with age, for ages 0 to 18 a higher share remaining predicts lower instantaneous scrappage, and for ages beyond 18 it predicts a higher instantaneous scrappage rate.

As ~~Table II-59~~~~Table VI-139~~ shows, all but the NPRM specification of the durability effect for pickups do not show autocorrelation in the error structures. However, similar to cars and SUVs/vans, the linear interaction of age and share remaining has the lowest AIC and highest adjusted R-squared. For this reason, this is the preferred specification for all body styles. Taking the ratio of the coefficient on share remaining to share remaining interacted with age shows that a higher share remaining will predict a lower instantaneous scrappage rate in the next period for ages 0 through 14, but a higher instantaneous scrappage rate for ages 15 and older.

Using the preferred forms of the engineering scrappage rates for each body style as the reference point, Section I.A.1.a)(1)(c)(iii)(d) considers different forms to predict the Gruenspecht effect for each body style. Section I.A.1.a)(1)(c)(iii)(e) uses the preferred engineering and Gruenspecht forms to consider alternative macroeconomic variables to predict the effects of the business cycle. Finally, Section I.A.1.a)(1)(c)(iii)(f) uses the preferred engineering, Gruenspecht and business cycle forms to consider the inclusion of other additional independent variables.

Table II-62

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Table VI-142 show the relationship between car, SUV/van, and pickup scrappage rates and changes in new vehicle price and fuel economies. The agencies consider two methods in response to comments outlined in Section I.A.1.a)(1)(b)(ii). 1) changes in average new vehicle prices net of 30 months of fuel savings (consistent with the technology selection and sales model) and 2) change in average new vehicle prices, change in average fuel prices, changes in new vehicle cost per mile and changes in new vehicle fuel consumption. We allow the elasticity of average new vehicle prices net of 30 months of fuel savings to vary by age by including interaction terms.

For all body styles, the specification of the Gruenspecht effect as the change in new vehicle prices net of fuel savings does not show signs of auto-correlated errors. However, for cars and vans/SUVs, the specification which separates the effect of new vehicle prices and fuel economy does show evidence of autocorrelation. For this reason, the changes in new vehicle fuel prices net of fuel savings is the preferred specification of the Gruenspecht effect.

The agencies consider the interaction of the change in average new vehicle prices with vehicle age. This relaxes an assumption that the elasticity of scrappage rates to change in new vehicle prices is constant. For cars and vans/SUVs the linear interaction of change to new vehicle prices net of fuel savings show evidence of autocorrelation. The quadratic interaction of age with change in new vehicle prices shows autocorrelation with cars. For this reason, the agencies consider the constant elasticity of scrappage rates to changes in new vehicle prices to be the preferred specification (as the only specification that does not show evidence of autocorrelation for all body styles). However, we do consider the quadratic form of the elasticity with age as a sensitivity case (even though there is evidence of autocorrelation (but only in the car specification)). This allows the agencies to test the impact of relaxing the assumption around constant elasticity on CAFE model outcomes.

(e) Considering Alternative/Additional
Macroeconomic Indicators

[Table II-63](#)~~Table VI-143~~ through [Table II-65](#)~~Table VI-145~~ show alternative macroeconomic indicators for cars, vans/SUVs and pickups, respectively. The agencies consider unemployment rate and per capita personal disposable income as alternatives to GDP growth rate to capture the cyclical component of the macro economy. The unemployment rate and the per capita personal disposable income are both I(1), so that the first difference of each is the form included. For the car and van/SUV specifications, the specifications replacing GDP growth rate show evidence of autocorrelation in the error structures. For this reason, the GDP growth rate is the preferred specification for the cyclical components of instantaneous scrappage rates, as in the NPRM models.

As discussed in Section (b)(iii)(c), some commenters were concerned with the exclusion of interest rates. In response, the agencies considered including the change in interest rates for the otherwise preferred specification. For vans/SUVs the model has a higher AIC and shows evidence of autocorrelation in the error structures. For pickups, the sign changes on the change in cost per mile when the interest rate is included, which would be an implausible result. Finally, the AIC for cars is nearly identical regardless as to whether the interest rate is included. For these reasons, the agencies continue to exclude the interest rate from the preferred specification.

(f) Considering Other Additional Variables

[Table II-66](#)~~Table VI-146~~ through [Table II-68](#)~~Table VI-148~~ show specifications that consider additional variables not included in the preferred specifications. As discussed in Section (b)(iii)(a), some commenters criticized the fact that maintenance and repair costs were excluded from the scrappage models. In response to comments, and since the maintenance and repair costs are I(1), the agencies considered including the difference in maintenance and repair costs. When included, changes in maintenance and repair costs show the expected sign—when maintenance and repair costs are higher, instantaneous scrappage rates are predicted to be higher (as used vehicles are more expensive to maintain). When included, the AIC is higher for the car and van/SUV specifications. That is, including the change in maintenance and repair costs does not improve the fit of the models. Because of this, and because there is no obvious way to predict future change to maintenance and repair costs (as discussed in the NPRM), the preferred specification continues to exclude maintenance and repair costs.

As discussed in Section (b)(iii)(b), some commenters criticized the exclusion of steel and iron scrap prices from the scrappage models. In response to comments, and since this variable is also I(1), the agencies considered including the change in steel and iron scrap prices. When included, the AIC of cars and vans/SUVs is higher. Further, the car specification includes evidence of autocorrelation in the error structures. In addition, there is no known projection of steel and iron scrappage prices, so that the agencies would have to make projections to include this variable in the scrappage models. Accordingly, the central case continues to exclude steel and iron scrap prices.

As discussed in Section (b)(iii)(d), some commenters and peer reviewers suggested that controlling for aggregate measures of model year cohorts, such as performance, might correct some unexpected signs. The preferred specification already addresses these concerns. Further, because fixed effects are included for model years, we cannot include aggregate model year specific attributes that are constant over the lifetime of the cohort. The agencies do consider the ratio of the average horsepower to weight of a model year cohort to the new vehicle cohort, as this will change along with changes to the horsepower to weight ratio over successive calendar years. Including this variable results in a higher AIC for cars and vans/SUVs and shows evidence of autocorrelation in the errors for these two body styles. For this reason, the preferred specification excludes this metric.

The agencies also considered including new vehicles sales directly as a predictor of instantaneous scrappage rates. Since new vehicle sales are I(1), the difference in new vehicle sales is the included form. Including the change in new vehicle sales results in a higher AIC for cars and vans/SUVs. It also introduces evidence of autocorrelation in the error structure for the car model, and reduces the effect of the change in fuel prices by two orders of magnitude for vans/SUVs. It seems unlikely that the magnitude of the effect of fuel prices would so drastically vary between body styles. For these reasons, the preferred specifications exclude the change in new vehicles sales. The agencies also considered including changes in vehicle stock, but this similarly did not improve the fit of the scrappage models—and doing so limited the ability to

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

link the sales and scrappage models as some commenters suggested (see Sections (b)(iv)(a) and (b)(iv)(b)).

(g) Projecting durability in the CAFE model

The left graphs in [Figure II-33Figure VI-58](#) through [Figure II-35Figure VI-60](#) show the fixed effects for the preferred scrappage specifications for cars, vans/SUVs, and pickups, respectively. For all body styles there is a general downward trend in the fixed effects. This suggests an increase in the durability of successive model years. However, since the panel datasets are not balanced, there is likely potential bias for the fixed effects that include only certain ages. This makes projecting the durability increase from the fixed effects a little more complicated than merely fitting to all fixed effects. First, we must determine what part of this trend is likely due to increases in vehicle durability (and should be projected forward) and which part of the trend may conflate other factors.

The right graphs in [Figure II-33Figure VI-58](#) through [Figure II-35Figure VI-60](#) show the average observed logistic scrappage rates by model year for all ages where data exists. As can be seen, the average observed scrappage rates decline dramatically for model years after 1996 for all body styles. There are two reasons this trend exists. First, as [Figure II-33Figure VI-58](#) through [Figure II-35Figure VI-60](#) show, the instantaneous scrappage rate generally follows an inverted u-shape with respect to vehicle age. The instantaneous scrappage rates generally peak between ages 15 and 20 for all body styles. Model year 1996 is the first model year which will be at least age 20 at the last date of available data (calendar year 2016). This means that all model years newer than 1996 have likely not yet reached the age where the instantaneous scrappage rate will be the highest for the cohort. Accordingly, the fixed effects could be biased downwards (consistent with the sharper downward slope in the fixed effects for most body styles for model years beyond 1996) because of the unbalanced nature of the panel, and not because of an actual increase in inherent vehicle durability for those model years.

The second reason the average logistic scrappage rates for model years before 1996 is more stable is because each data point in the average has increasingly less effect on the average as more data exists. For model years 1996 and older there are at least 18 data points (we start the scrappage at age 2, by which point effectively all of a model year has been sold), and each will have a smaller effect on the average than for newer model years with fewer observations. For these reasons, the average observed logistic scrappage rate is more constant for model years before 1996. As a result, we do not consider the trend in fixed effects after model year 1996 to rely on enough historical data to represent a trend in vehicle durability, as opposed to a trend in the scrappage rate with vehicle age.

In considering which model year fixed effects should be considered in projecting durability trends forward, another important factor is whether there are discrete shifts in the types of vehicles that are in the market or category of each body style over time. For cars, an increasing market share of Japanese automakers which tend to be more durable over time might result in fixed effects for earlier model years being higher. This trend is shown in the fixed effects in [Figure II-33Figure VI-58](#), which follow a steeper trend before model year 1980.

Figure II-3364 - Trends in fixed effects for preferred car specification

For vans/SUVs, earlier model years are more likely to be built on truck chassis (body-on-frame construction) instead of car chassis (unibody construction). Since pickups tend to be more durable, the earlier fixed effects are likely to be lower for vans/SUVs for earlier model years. The 1984 Jeep Cherokee was the first unibody construction SUV.¹⁷⁰⁹ As Figure II-3465 shows, the fixed effects before 1986 show inconsistent trends; these are likely due to changes in what was considered a van/SUV over time. For this reason, the agencies build the trend of fixed effects from model years 1986 to 1996.

Figure II-3465 - Trends in Fixed Effects for Preferred Van/SUV Specification

¹⁷⁰⁹ <https://www.autoguide.com/auto-news/2018/01/10-interesting-facts-from-the-history-of-the-jeep-cherokee.html>

Figure II-3566 - Trends in Fixed Effects for Preferred Pickup Specification

While the trend for pickups and cars could be extrapolated before 1986, the agencies opt to keep the fixed effects included constant for all body styles. Thus, the projections are built from model year 1986 to model year 1996 fixed effects (the filled in data points in [x] through [y]). Table II-69Table VI-149 below, shows the linear regressions shown as the line on the left side of Figure II-31Figure VI-56 through Figure II-33Figure VI-58. The durability cap represents the last model year where the durability trend is assumed to persist. We cap the durability impacts at model year 2000, as data beyond this point does not exist for enough ages to determine if durability has continued to increase since this point. The implication of this cap, is that model years after 2000 are assumed to have the same initial durability as model year 2000 vehicles. Since there is a limit to the potential durability of vehicles, this acts as a bound on this portion of the scrappage model.

Table II-69Table VI-142 - Durability Inputs in the CAFE Model

Beta Coefficients	Inputs	Cars	Vans/SUVs	Pickups
β_{12}	Intercept	21.13195	25.488	54.52891
β_{13}	MY	-0.01141	-0.01364	-0.02879
β_{14}	MY Durability Cap	2000	2000	2000

The durability projections enter the scrappage equation in the CAFE modelling in accordance to the following equation:

$$\ln\left(\frac{S_{MY,CY}}{1 - S_{MY,CY}}\right) = \beta_0 * Age_{MY,CY} + \beta_1 * Age^2_{MY,CY} + \beta_2 * Age^3_{MY,CY} +$$

$$Share Remaining_{MY,CY} * (\beta_3 + \beta_4 * Age_{MY,CY}) +$$

$$Diff(New Price - FS)_{CY} * (\beta_5 + \beta_6 * Age_{MY,CY} + \beta_7 * Age^2_{MY,CY} + \beta_8 * Age^3_{MY,CY}) +$$

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

$$\beta_9 * Diff(Fuel Price)_{CY} + \beta_{10} * Diff(CP100M_{MY})_{CY} + \beta_{11} * GDP Growth_{CY} + \beta_{12} + \beta_{13} * MY_{MY} - \text{ifelse}(MY_{MY} > \beta_{14}, \beta_{13} * (MY_{MY} - \beta_{14}), 0)$$

The intercept enters as a constant added to the predicted logistic of the instantaneous scrappage rate. The model year slope enters as the model year for all model years older than 2000 and enters as 2000 for all model years 2000 and newer.

Once the predicted logistic scrappage rate is calculated in the CAFE model (including the projections of the fixed effect portion of the equation), the future population of model year cohorts can be predicted. The instantaneous scrappage can be calculated directly from S. It identifies the share of remaining vehicles in each calendar year that are scrapped in the next year. The population of vehicles in the next calendar year can be calculated as follows:

$$Population_{MY,CY+1} = Population_{MY,CY} * (1 - s_{MY,CY}).$$

This process is iteratively calculated at the end of the CAFE model simulation to determine the projected population of each model year in each future calendar year. This allows the calculation of vehicle miles travelled, fuel usage, pollutant and CO₂ emissions, and associated costs and benefits. The CAFE model documentation released with this final rule further details how the scrappage model is projected within the simulations.

(h) Updates to the Decay Function

The scrappage models described above fit the historical data of car and truck scrappage well, but when used to project the scrappage of future model years they over-predict the remaining cars and trucks for ages greater than 30 in an unrealistic manner. Nearly six percent of the MY2015 van/SUV fleet and eight percent of the pickup fleet is projected to persist until age 40. This is unrealistic, and likely due to the fact that the agencies do not observe enough model years for those ages and over-predict the impact of durability increases for those ages. For this reason, we are using the curves with an accelerated decay function to predict instantaneous scrappage beyond age 30 for pickups and SUVs/vans. The implementation and parameter stricture of the decay function have not changed since the NPRM model. [Table II-70Table VI-150](#), below, shows the inputs used for the final rule analysis.

Table II-~~70~~43 - Decay Function Inputs

Beta Coefficients	Inputs	Cars	Vans/SUVs	Pickups
β_{15}	Decay Age	30	30	30
β_{16}	Final Survival Rate	0.01	0.025	0.025

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The final survival rate has not changed since the NPRM, but the input *Decay age* has changed. In the NPRM, the decay function was specified to begin after age 20, while the decay function begins after age 30 in the final rule analysis. This input change was possible because the scrappage model for the final rule predicts shares remaining in line with observed historical trends through age 30, rather than through age 20. This improvement in the model fits for older ages is driven both by the shift of the modelling of the durability effect discussed in Section I.A.1.a)(1)(c)(iii)(g) and the increase in available data on the scrappage rates of older vehicles discussed in Section I.A.1.a)(1)(c)(ii)(d). Overall, this outcome suggests that the final rule model predicts the scrappage rates of older vehicle better than the NPRM model.

As in the NPRM, the decay function is implemented in the model using the following conditions:

If ($age < \beta_{15}$),

$$S = \frac{e^{\sum \beta_i X_i}}{1 + e^{\sum \beta_i X_i}}$$

And:

$$Population_{MY,CY+1} = Population_{MY,CY} * (1 - S_{MY,CY}).$$

If ($age \geq \beta_{15}$),

$$Population_{MY,CY+1} = Population_{MY,CY=\beta_{15}} * \exp^{rate*t}$$

Where:

$$t = (age + 1 - \beta_{15})$$

And:

$$rate = \frac{\ln\left(\frac{\beta_{16}}{Population_{MY,CY=\beta_{15}}}\right)}{40 - \beta_{15}}$$

Here, the population for ages beyond the start age of the decay function depends on the population of the cohort at that start age and the final share expected for that body style at age 40. The rate of decay necessary to make the final population count equal that observed in the historical data is applied.

(iv) Projections and Implications for Lifetime VMT

[text forthcoming]

(4) *The Rebound Effect in the NPRM*

The fuel economy rebound effect—a specific example of the well-documented energy efficiency rebound effect for energy-consuming capital goods—refers to the tendency of motor vehicles' use (as measured by vehicle-miles traveled, or VMT) to increase when their fuel economy is improved and, as a result, the cost per mile (CPM) of driving declines. Amending and establishing CAFE and CO₂ standards at a lower degree of stringency than the baseline level will lead to comparatively lower fuel economy for new cars and light trucks, thus increasing the amount of fuel consumed to travel each mile. The resulting increase in CPM will lead to a reduction in VMT over the lifetime of new vehicles, an example of the rebound effect working in reverse. In the NPRM, the agencies assumed a fuel rebound effect of 20 percent, meaning that a 5 percent decrease in fuel economy would result in a one percent decrease in the annual number of miles driven at each age over a vehicle's lifetime.

Many of the comments received on different components of the CAFE model can be traced back to the agencies' rebound selection. The agencies recognize that the value selected for the rebound effect influences overall costs and benefits associated with the regulatory alternatives under consideration as well as the estimates of lives saved under various regulatory alternatives, and that the rebound estimate, along with fuel prices, technology costs, and other analytical inputs, is part of the body of information that agency decision-makers have considered in determining the final levels of the CAFE and CO₂ standards. The agencies also note that the rebound effect diminishes the economic and environmental benefits associated with increased fuel efficiency.

For the analysis supporting the NPRM, the agencies conducted a thorough re-examination of the basis for the estimate of the fuel economy rebound effect used to analyze the impacts of CAFE and CO₂ emission standards for model years 2012-16 and 2017-21. This was prompted by three developments. First, more recent updates of the 2007 study by Small and Van Dender that had provided the basis for assuming the 10 percent rebound effect used in those previous analyses reported larger values. Second, projected growth in the income measure used in those authors' 2007 study, which was anticipated to reduce the magnitude of the rebound effect over the future period spanned by those analyses, did not occur during the decade following the 2007 study's publication. Finally, extensive new research on the rebound effect had become available since those previous analyses were conducted, and while its findings were mixed, many of those more recent studies reported values significantly above the agencies' previous 10 percent estimate.

In the NPRM, the agencies first summarized estimates of the fuel economy rebound effect for light-duty vehicles in the U.S. from studies conducted through 2011, when the agencies originally surveyed research on this subject. As the accompanying discussion in the proposal indicated, the research available through 2011 collectively suggested that the rebound effect was likely to fall in the range from 20 percent to 25 percent, although the then-recent study by Small and Van Dender (2007) pointed to smaller values, particularly for future years. The agencies then identified 16 additional studies of the rebound effect that had been conducted since their original survey, and the NPRM discussed the various approaches they used to measure the

magnitude of the rebound effect, their data sources and estimation procedures, reported findings, and strengths and weaknesses of each study.

Based on this re-examination, the agencies concluded that currently available evidence did not appear to support the 10 percent estimate relied upon in previous rules, and identified a value of 20 percent as more representative of the totality of evidence, including both the research covered by the earlier and more recent studies examined in the NPRM. While acknowledging the wide range of estimates reported in more recent research—which extended from zero to more than 80 percent—the agencies noted that the central tendency of recent estimates appeared to lie in the same 20-25 percent range suggested by their extensive review of earlier research. The agencies also recognized that a 20 percent estimate differed markedly from the 10 percent estimate used in the regulatory analyses for the 2010 and 2012 final rules, but noted that it represented a return to the value NHTSA originally used to analyze the impacts of CAFE standards for model years prior to 2011.

(a) Comments on the Rebound Effect Used in the NPRM

The agencies received numerous comments on the decision to revise their previous estimate of the rebound effect, virtually all of which echoed a few common arguments. First, commenters generally agreed that the most appropriate measure for the agencies to rely on is the current long-run fuel economy rebound effect for U.S., although a few suggested that using an estimate of its short-run value might be preferable.¹⁷¹⁰ However, many commenters argued that some of the more recent studies the agencies relied upon to support the revised 20 percent estimate may have limited relevance to the appropriate measure for analyzing the current rule, and that the agencies should place more emphasis on those that commenters asserted were more appropriate to rely upon.

To identify the most relevant research, some commenters proposed applying various selection criteria to choose which studies were most appropriate to rely on when estimating the value of the rebound effect to use in this analysis. While commenters proposed using certain criteria as “filters”—that is, to eliminate any studies that did not meet those criteria—they also suggested applying other criteria to emphasize studies with particular features they argued made them more relevant to identifying the current value of the rebound effect for the U.S.¹⁷¹¹ Among these suggested criteria were the following:

¹⁷¹⁰ See, e.g., RFF, Comments, NHTSA-2018-0067-11789, at 30. For an thorough example of the arguments made for a short- to medium-term rebound effect, see generally IPI, Appendix, NHTSA-2018-0067-12213, at 61.

¹⁷¹¹ See, e.g., IPI, Appendix, NHTSA-2018-0067-12213, at 58-64; EDF, Analysis of the Value and Application of the Rebound Effect, NHTSA-2017-0069-0574, at 16-19; California Office of the Attorney General et al., Attachment1, NHTSA-2017-0069-0625, at 8; States and Cities, Attachment 1, Docket No. NHTSA-2018-0067-11735, at 78; RFF, Comment, NHTSA-2018-0067-11789, at 3; CARB, Detailed Comments, NHTSA-2018-0067-11873, at 120; Aluminum Association, Comments, NHTSA-2018-0067-11952, at 5; NCAT, Appendix A, NHTSA-2018-0067-11969, at 34; and North Carolina Department of Environmental Quality, Comments, NHTSA-2018-0067-12025, at 12; among others. EPA’s Science Advisory Board shared similar policy opinions. SAB at 26-27.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- Exclude estimates based upon data from outside the U.S.;
- Include only estimates based upon “more recent” data, usually taken to mean those published within approximately the last decade;
- View estimates based on the U.S. 2009 National Household Travel Survey skeptically, or exclude them from consideration completely;
- Emphasize estimates derived from vehicle use and fuel economy data spanning multiple years (such as aggregate time-series or panel data), while according less weight to those based on a single-year cross section (such as most household survey data);
- Emphasize estimates of the rebound effect that measure the response of vehicle use to variations in fuel efficiency, rather than in fuel cost per mile driven or fuel price per gallon;
- Emphasize estimates that rely on identification strategies that account for potential endogeneity in fuel economy (as would result, for example, if households with high levels of demand for travel purchase vehicles with higher fuel economy);
- Emphasize estimates based on measures of vehicle use obtained from odometer readings; and
- Emphasize estimates that explicitly control for purchase prices of new vehicles in order to account for changes in new vehicle prices due to CAFE standards.

A few commenters illustrated how applying these criteria could reduce the large number of published studies of the rebound effect to a limited subset that suggested a smaller value than 20 percent.¹⁷¹² Using multiple criteria to exclude or de-emphasize studies that did not meet all of those applied, these commenters argued that the most appropriate value for this analysis was closer to (or possibly even below) the 10-percent estimate the agencies used for the previous rulemaking.¹⁷¹³ However, one commenter noted that applying these criteria individually to exclude any estimates not meeting them had almost no effect on formal measures of the central tendency (the mean and median values) of the remaining estimates.¹⁷¹⁴ This commenter suggested that only by applying two or more of these criteria jointly and excluding any studies that did not meet all of those applied could the universe of research on the rebound effect be reduced to a subset supporting a lower value than the 20 percent figure the agencies used to analyze the NPRM.

¹⁷¹² See, e.g., Gillingham, Nera-Trinity Responses, NHTSA-2018-0067-12403, at 16-30.

¹⁷¹³ See *supra* note 17112.

¹⁷¹⁴ Alliance of Automobile Manufacturers, Attachment 3, NHTSA-2018-0067-12386, at 15-17.

Commenters also identified several additional recent studies that were not included in the agencies' review of recent evidence for the NPRM, and suggested revised interpretations of the empirical estimates reported in two studies that had been included (the agencies also clarified a third). Commenters represented these additional studies as generally supporting lower values than the agencies' revised 20 percent estimate, although this appeared to be a selective interpretation of some of the results they reported.¹⁷¹⁵ Other commenters asserted that the two most commonly-demonstrated features of the rebound effect are that it varies directly with fuel prices and declines in response to rising income over time, and argued that the latter suggests that a declining value is likely to be more appropriate for analyzing the longer-term impacts of this final rule.¹⁷¹⁶

Some commenters suggested that the rebound effect is asymmetrical, meaning that drivers are more responsive to price increases than price decreases. These commenters asserted that the asymmetrical nature of the rebound effect favors a lower estimate.¹⁷¹⁷ Similarly, other commenters suggested that the rebound effect had to be lower than 20 percent because congestion would limit additional driving.¹⁷¹⁸

(b) *Agencies' Response to Comments on the NPRM*

In response to commenters who argued that the agencies' estimate of the rebound effect should be reduced, because research that incorporates the effects of congestion or allows asymmetrical responses to price changes suggests lower values, the agencies note that, for the final rule's analysis, those factors would be difficult and perhaps even inappropriate to incorporate in their analysis. In the case of congestion, the agencies note that their estimate of the rebound effect—like research on the rebound effect in general—represents a change in aggregate VMT, and has no clear implication about how that change in travel is likely to be distributed over times of the day or geographic locations.¹⁷¹⁹

¹⁷¹⁵ For example, some commenters (*e.g.*, Gillingham, Nera-Trinity Responses, NHTSA-2018-0067-12403, Table 2, at 24) represented the recent analysis of vehicle use data from Texas by Wenzel and Fujita as reporting a rebound effect of 8-15 percent, which appears to be based on those authors' estimates of the response of vehicle use to changes over time in fuel prices alone. This range appears to ignore those same authors' estimates of the sensitivity of vehicle use to variation in fuel costs per mile, which provides a more direct measure of the fuel economy rebound effect because it incorporates fuel economy as well as fuel prices. Those estimates range from 7-40 percent, with most falling in the interval from 15-25 percent; *see generally*, Wenzel and Fujita (2018), Table 4-12, at 38.

¹⁷¹⁶ *See particularly* Small, NHTSA-2018-0067-7789, at 3.

¹⁷¹⁷ EDF, Analysis of the Value and Application of the Rebound Effect, NHTSA-2017-0069-0574, Comment, 37-38.

¹⁷¹⁸ For example, the South Coast Air Quality Management District argued that, logistically, rebound cannot exist in Southern California because "any rebound effect will only worsen congestion in Southern California, such a result cannot be predicted." NHTSA-2018-0067-11813 at 45.

¹⁷¹⁹ The agencies' estimate of increased congestion costs associated with additional driving due to the rebound effect implicitly assumes that increased driving will be distributed according to current travel patterns, producing similar proportional increases at various hours of the day and geographic locations. Such an assumption is made out of necessity to model congestion and noise; the agencies acknowledge that the rebound effect is unlikely to affect vehicle use in such a uniform fashion.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

As for possible asymmetry in the response of vehicle use to changes in driving costs, the CAFE model applies a single estimate of the rebound effect for all changes in cost-per-mile, and cannot accommodate a rebound effect that varies with the magnitude or direction of changes in driving costs, which would be necessary to capture asymmetrical or non-linear responses to cost changes. The agencies also remind commenters that this rule will result in an increase in driving costs, for which the research they cite generally suggests a *larger* value of the rebound effect is appropriate. In any case, using a different estimate of the rebound effect to analyze impacts of raising and lowering standards would not promote consistency or replicability, both desirable characteristics of regulatory analysis.

The agencies decided to include the previously omitted studies raised by commenters in their rebound analysis supporting the final rule, but do not feel that they suggest a value different from that used to analyze the proposal. Adding these studies to the list of recent research discussed in the NPRM, deleting one unpublished analysis, and revising the entries for selected studies to reflect more accurately the values reported by their authors produces a more extensive catalog of recent research, which is summarized in [Table II-71](#) ~~Table VI-151~~ below.

Table II-~~71~~¹⁴⁴ – Recent Estimates of the Rebound Effect for Light-Duty Vehicles

Stapleton <i>et al.</i> (2017)	Great Britain	1970-2012	annual aggregate values	22-30%
Wenzel and Fujita (2018)	Texas	2005-2010	32 million vehicles	7-40%
Knittel and Sandler (2018)	California	1996-2010	36 million vehicles	5-27%

As evidenced in [Table II-71](#)~~Table VI-151~~, studies continue to have a wide range of estimates, but collectively the research looks remarkably similar to the historical estimates. The newer studies suggest that a plausible range for the rebound effect is 10-50 percent. The central tendency of this range appears to be roughly 30 percent.

In response to comments proposing the application of specific criteria to eliminate or reduce the consideration accorded to studies without certain features thought to increase the relevance of their findings, the agencies note that measuring the rebound effect is both conceptually and technically challenging, and that analysts have used many different approaches in an attempt to surmount these challenges. The agencies' view is that each of the studies included in its previous survey and in [Table II-71](#)~~Table VI-151~~ above provides some useful evidence on the likely value of the rebound effect, and while all have some conceptual or theoretical weaknesses, each nevertheless provides some useful insights into the appropriate magnitude of the rebound effect for the current analysis.

As a general approach to estimating parameters that are uncertain, the agencies prefer to rely on the totality of empirical evidence, rather than restricting the available evidence by

categorically excluding or according less weight to that do not meet selection criteria that may not be widely agreed upon. From this perspective, analyses that rely on different measurement approaches, data sources, and estimation procedures all have the potential to provide valuable information for choosing the most representative value. The agencies also view sound measurement strategies and careful empirical analysis using reliable data as equally important features when compared to a study's vintage or geographic scope. Examining the widest possible range of research also enables useful comparisons and "cross-checks" on the estimates that individual studies report.

Notwithstanding this more inclusive perspective, the agencies endorse certain of the characteristics preferred by commenters, although the agencies view them as indicators of a strong study, rather than a bright-line test of whether to accord it any weight rather than discarding it from consideration. Specifically, the agencies agree with many commenters that both the extended time span encompassed by their analysis of the impacts of CAFE and CO₂ standards and the long expected lifetimes of vehicles subject to this final rule means that estimates of the long-run rebound effect are most relevant for purposes of the final rule analysis.¹⁷²⁰ The agencies also agree with commenters that estimates based upon more recent data are generally preferable, but nevertheless note that older studies that combine careful analysis with unusually reliable or novel data can offer evidence that remains useful.¹⁷²¹ The agencies also concur with some commenters' argument that estimates of the rebound effect that are derived from the relationship of vehicle use to fuel efficiency, rather than to fuel cost per mile or gasoline prices, are likely to provide more direct measures of the fuel economy rebound effect itself, which is the desired parameter for the purposes of this analysis. Finally, the agencies generally view identification strategies and econometric methods that account or control for potential endogeneity in fuel economy as likely to provide more reliable estimates.

In contrast, the agencies view other criteria proposed by commenters as unnecessarily restrictive, particularly when they are used to disqualify otherwise informative research from consideration. For instance, categorically excluding from consideration non-U.S. studies—which the agencies agree should be treated cautiously—seems likely to exclude useful evidence, particularly recognizing some of those studies' access to unusually reliable data on vehicle use and fuel economy and use of sophisticated econometric analysis. In addition, many foreign studies have been conducted in nations with income levels comparable to the U.S., and in some cases levels of auto ownership that are beginning to approach U.S. levels. Furthermore, driving

¹⁷²⁰ Most of the vehicles affected by today's standards will remain on the roads for at least a decade, with a significant fraction surviving considerably longer. As such, long-run estimates are more likely to reflect the lifetime mileage accumulation of the new fleet than either short-run or medium-run estimates. Furthermore, a long-run rebound estimate better reflects the cumulative impact of successive CAFE and CO₂ standards such as those adopted by the agencies beginning as early as 2010.

¹⁷²¹ One example is the study by Greene et al. (1999), which used advanced econometric analysis of unusually detailed and reliable data on household demographic and economic characteristics, household members' use of individual vehicles, and fuel purchases to estimate the response of households' use of individual vehicles to their actual on-road fuel economy, and its implications for total household driving.

habits throughout the U.S. are not homogenous. In fact, some regions in the U.S. may exhibit driving habits that more closely resemble those in some foreign nations than driving patterns in other regions of the U.S.¹⁷²²

In response to some commenters' recommendation that the agencies more heavily weigh studies using data spanning multiple years than those relying on data for a single year, the agencies note that household surveys, the most common form of data for a single year, provide cross-sectional variation in vehicle use and other characteristics that is helpful for identifying the desired long-run measure of the rebound effect. Household surveys are also an important source of information that enable analysts to measure the response of individual vehicles' use to variation in their fuel economy, while also controlling adequately for household characteristics that affect travel patterns and vehicle use. Household survey data can also enable analysts to identify the vehicle substitution patterns within multiple-vehicle households that are increasingly responsible for producing the rebound effect, while even modest-scale household surveys include many more observations than are typically available in aggregate time-series or panel data.

These strengths of course need to be balanced against the potential drawbacks of relying on a one-time snapshot of households' behavior during a single time period. Surveys also frequently rely on owner-reported estimates of vehicle use and usually require analysts to impute vehicles' fuel economy ratings from limited and sometimes incomplete information on the specific vehicle models and vintages that households report owning. One result is that estimates of the rebound effect derived from household survey data may be based on inaccurate estimates of vehicles' use and fuel economy. Assuming the errors in measuring these variables are random, the errors would increase the uncertainty surrounding the estimates of the rebound effect, but would not bias the estimate.

In contrast, studies using nationwide aggregate or average measures of vehicle use and fuel economy or fuel cost rarely provide adequate independent variation to support reliable estimates of the response of vehicle use to variation in fuel economy, even where extended time series are available, while State-level measures of these variables are subject to potentially extreme measurement error that can compromise estimates of these relationships.¹⁷²³ Moreover, controlling for the many other demographic and economic factors likely to affect vehicle use using national or even State-level aggregate data presents difficult challenges.

Finally, the agencies note that no single selection criterion proposed by commenters noticeably reduces the central tendency displayed by the universe of estimates of the rebound

¹⁷²² For example, drivers in Manhattan, Kansas likely respond to changes in fuel prices and fuel economy differently than drivers in Manhattan, New York.

¹⁷²³ For example, State-level estimates of travel by individual vehicle classes such as cars and light-duty trucks often exhibit implausible year-to-year variability due to the measurement procedures states employ and the difficulty of distinguishing among different types of vehicles. At the same time, the potential geographic "mismatch" between State-level vehicle use and fuel sales complicates any effort to measure fuel efficiency or fuel costs at the State level.

effect, and multiple criteria must be applied simultaneously to restrict the universe to a subset of studies that points toward a significantly lower value than the 20 percent estimate the agencies used to analyze the proposal. Applying multiple criteria drastically reduces the number of studies that remain available to guide the agencies, while at the same time discarding potentially valuable information provided by research those criteria exclude from consideration.¹⁷²⁴ Doing so would thereby necessarily reduce the confidence that the agencies can have in the resulting estimate.

Regarding some commenters' assertion that the rebound effect is known to decline in response to rising income, and that this observation warrants using a lower value for long-term future evaluation of the standards' effects, the agencies note that some evidence based on household and vehicle use surveys suggests that the rebound effect increases with the level of household vehicle ownership, which is itself highly correlated with income. Together with forecasts of limited future growth in most measures of U.S. household income, this finding casts some doubt on whether the rebound effect is likely to decline over the time period spanned by the agencies' analysis.¹⁷²⁵

The agencies also note that one of the studies cited in ~~Table II-71~~~~Table VI-151~~ above (DeBorger et al., 2016) finds that the decline in the fuel economy rebound effect with income reported in the earlier analysis by Small and Van Dender (2007)—on which the agencies relied in reducing their original estimate of the rebound effect to 10 percent—results entirely from a reduction in drivers' sensitivity to fuel prices as their incomes rise, rather than from any effect of rising income on the sensitivity of vehicle use to fuel economy.¹⁷²⁶ This latter measure—which DeBorger et al. find is quite small and has not changed significantly as incomes have risen over time—is the most direct measure of the fuel economy rebound effect, so their analysis calls into question its widely-assumed sensitivity to income.

Finally, because there is not a clear consensus around a single rebound estimate within the literature, the agencies believe it is important to benchmark their analysis with other large scale surveys of the literature published by neutral observers. In one early survey, Greening, Greene, and Difiglio (2000) reviewed studies that estimated the rebound effect for light-duty vehicles in the U.S., concluding that those relying on aggregate time-series data found it was likely to range from 10-30 percent, while those using cross-sectional analysis of household

¹⁷²⁴ As an illustration, excluding non-U.S. studies reduces the number of recent analyses surveyed in the proposal from 15 to 8, while eliminating those that rely on the 2009 National Household Travel Survey (NHTS) discards another 5, leaving only 3.

¹⁷²⁵ For example, the widely cited IHS Markit Long-Term Macroeconomic Outlook for Spring 2019 projects that per Capita disposable personal income in the U.S. will grow at 1.6 percent annually over the next 30 years; see Federal Highway Administration, Forecasts of Vehicle Miles Traveled (VMT): Spring 2019, Table 2, available at https://www.fhwa.dot.gov/policyinformation/tables/vmt/vmt_forecast_sum.cfm.

¹⁷²⁶ DeBorger, B., Mulalic, I., and Rouwendal, J., "Measuring the rebound effect with micro data: A first difference approach." *Journal of Environmental Economics and Management*, 79 (2016), at 1-17.

vehicle use suggested a larger rebound effect, in the range of 25-50 percent.¹⁷²⁷ Sorrell et al. (2009) found that the magnitude of the rebound effect for personal automobile travel is likely to fall in the 10-30 percent range, with some evidence suggesting that the lower end of that range might be most appropriate.¹⁷²⁸

Most recently, a meta-analysis of 74 published studies of the rebound effect conducted by Dimitropoulos et al. (2018) estimated that the long-run rebound effect ranges from 22-29 percent when measured by the response of vehicle use to variation in fuel efficiency (the authors' preferred measure), from 21-41 percent when it is measured using the variation fuel cost per unit distance, and from 25-39 percent using fuel price per gallon.¹⁷²⁹ The authors concluded that "the magnitude of the rebound effect in road transport can be considered to be, on average, in the area of 20%," but noted that the long-run estimate was about 32 percent.¹⁷³⁰ A subsequent published study by these same authors (Dimitropoulos et al. (2018)) concludes that the most likely estimate of the long-run rebound effect is in the range of 26-29 percent, but could range from as low as 15 percent to as high as 49 percent at income levels, development densities, and fuel prices that are currently representative of the U.S.¹⁷³¹

*(c) Selecting a Value of the Rebound Effect for
Evaluating the Impacts of this Rule*

After reviewing the evidence on the rebound effect previously summarized in the NPRM, comments the agencies received, other recent studies of the rebound effect that were not summarized in the NPRM but suggested by commenters, and published surveys of literature, a reasonable case can be made to support values of the rebound effect at least as high as 30 percent. The totality of evidence, without categorically excluding studies on grounds that they fail to meet certain criteria, and evaluating individual studies based on their particular strengths, suggests that a plausible range for the rebound effect is 10-50 percent. The central tendency of this range appears to be at or slightly above its midpoint, which is 30 percent. Considering only those studies that the agencies believe are derived from unusually reliable data, employ identification strategies that are likely to prove effective at isolating the rebound effect, and

apply rigorous estimation methods suggests a range of approximately 10-45 percent, with most of their estimates falling in the 15-30 percent range.¹⁷³²

At the same time, the agencies conclude that a reasonable case can also be made to support values of the rebound effect falling in the 5-15 percent range. This argument relies on using the criteria proposed by commenters to restrict the studies considered to include recently published analyses using U.S. data, and to accord the most weight to research that relies on measures of vehicle use derived from odometer readings, controls for the potential endogeneity of fuel economy, and estimates the response of vehicle use to variation in fuel economy itself, rather than to fuel cost per distance driven or fuel prices. This approach suggests that the rebound effect is likely in the range from 5-15 percent, and is more likely to lie toward the lower end of that range. The agencies note that estimates of very low or no rebound effect cited by some commenters are either misinterpretations of the findings reported by their authors, or do not represent measures of the fuel economy rebound effect.¹⁷³³

Finally, the agencies note that surveys of evidence on the rebound effect have consistently found that the most appropriate estimate falls in the range of 10-40 percent. These findings have remained surprisingly consistent over time, despite a rapidly expanding universe of empirical evidence that includes estimates drawn from more diverse settings, and reflects continuing improvements in the data they rely upon, an expanding range of strategies for identifying the rebound effect and distinguishing it from other influences on vehicle use, and advances in the econometric procedures analysts use to estimate its magnitude.

For the aforementioned reasons, the agencies have elected to retain the 20 percent rebound effect used to analyze the effects of the NPRM on vehicle use and fuel consumption for analyzing the comparable effects of this final rule. As explained above and in the NPRM, older research suggests a rebound of 20 to 25 percent. The new research in [Table II-71](#) ~~Table VI-154~~ supports a similar—or even larger—range. Extensive survey studies support a rebound at or above 20 percent. As such, the agencies feel 20 percent is a reasonable—and probably even conservative—estimate of the totality of the evidence. While a lower estimate may be reasonable under certain circumstances, the agencies are uncomfortable making the requisite

¹⁷³² As indicated previously, these are the selection criteria proposed by commenters with which the agencies concur. In chronological order, the studies the agencies feel best meet those criteria include Greene et al. (1997), Small and Van Dender (2007) and subsequent updates by Hymel, Small, and Van Dender (2010,2015), Linn (2016), Anjovic and Haas (2012), Gillingham (2014), and DeBorger et al. (2016). Other studies the agencies believe warrant serious consideration because they offer some or most of these same advantages include those by Liu et al. (2014), Knittel and Sandler (2018), and Wenzel and Fujita (2018).

¹⁷³³ For example, some commenters misinterpret Greene's (2012) inability to identify a statistically significant estimate of the response of vehicle use to variation in fuel economy as evidence that its true value is zero. Similarly, some commenters misinterpret the result reported by West et al. (2017) that buyers of more fuel-efficient vehicles did not increase their driving as evidence that fuel economy itself has no effect on vehicle use, when—as the study's authors and some commenters acknowledge—it reveals instead that buyers regarded those vehicles as providing inferior transportation service and drove them less as a consequence. Because the agencies repeatedly insist that vehicle attributes other than fuel economy will not change as a consequence of this rule, those authors' finding is of limited or no relevance to the analysis supporting this rule.

assumptions regarding which specific criteria should be used to identify relevant studies and relying on a subset of the literature for the central analysis. However, recognizing the uncertainty surrounding the rebound value, the agencies also examine the sensitivity of those estimated impacts to values of the rebound ranging from 10 percent to 30 percent, both in isolation and in conjunction with plausible variation in other key parameters.

(5) *Vehicle Miles Traveled (VMT)*

VMT directly influences many of the various effects of fuel economy and CO₂ standards that decision-makers consider in determining what levels of standards to set. For example, fuel savings is a function of a vehicle's efficiency, miles driven, and fuel price. Similarly, factors like criteria pollutant emissions and fatalities are direct functions of VMT. In the CAFE model, VMT is the product of average usage per vehicle in the fleet and fleet composition, which is itself a function of new vehicle sales and vehicle retirement decisions, otherwise known as scrappage. These three components—average vehicle usage, new vehicle sales, and older vehicle scrappage—jointly determine total VMT in each alternative.

As the following discussion explains, today's VMT analysis provides aggregate results comparable to other well-regarded VMT estimates. However, because the agencies' analysis looks at the incremental costs and benefits across alternatives (see Section VII), it is more important that the analysis capture the variation of VMT across alternatives than accurately to predict total VMT consumption within a scenario. As such, the agencies note that today's VMT estimates are logical, consistent, and precise across alternatives. Furthermore, as will be described in further detail below, while the agencies, in response to comments, have decided to modify their approach to calculating VMT and to use different VMT estimates than those used in the NPRM, the general trends between alternatives are comparable.

Commenters addressed a number of topics related to the total amount of estimated VMT, the incremental differences in estimated VMT between regulatory alternatives, and per-vehicle VMT estimates in the NPRM analysis. In general, commenters felt that the NPRM's VMT numbers were inaccurate and should not be relied on for the analysis.¹⁷³⁴ Some commenters were more specific and argued that the total amount of estimated VMT projected in the NPRM started at too low a level, and increased too much over the years simulated. Similarly, some commenters argued that the agencies' estimates were too different from other recognized estimates and suggested that the agencies benchmark VMT projections to other sources to ensure both a consistent starting point and comparable VMT throughout the calendar years analyzed.

A few commenters objected to the underlying mileage accumulation schedules, which form the basis for per-vehicle VMT estimates in CAFE Model simulations. Such commenters speculated that revisions to these schedules undertaken in 2016 might be the reason for discrepancies in total VMT. Other commenters were less concerned about how VMT was

¹⁷³⁴ See, e.g., Securing America's Energy Future, NHTSA-2018-0067-11981 at 37-38.

computed within each scenario but were apprehensive about differences in VMT estimates across regulatory alternatives. For instance, Honda argued that, “[a]ssuming all other parameters are held constant—and excluding the rebound effect—it is not obvious why one scenario should have different total VMT than another.”¹⁷³⁵ While commenters generally provided few specific recommendations about the level to which VMT estimates should be constrained among alternatives, several commenters argued that VMT projections would benefit from consideration of travel demand modeling.

The agencies carefully assessed all comments. To address them, the agencies have revised their calculation of estimated VMT in two, significant respects. First, in response to comments regarding the mileage accumulation schedules, the agencies have revised the schedules using panel data. Second, to deal with commenters’ concerns with the fluctuation of estimated “non-rebound” VMT across regulatory alternatives, the agencies have created a method that constrains “non-rebound” VMT across regulatory alternatives. The agencies believe these two changes collectively resolve the substantive issues raised by commenters. The total VMT for the final rulemaking (FRM) analysis now aligns with estimates of the Federal Highway Administration (FHWA) and the only differences in VMT between alternatives is attributable to changes in the fleet’s fuel economy. The following sections discuss these changes in detail.

(a) *Integration of sales, scrappage, and VMT*

Additionally, some commenters (RFF, IPI, NRDC) argued that a superior, and perhaps even necessary, approach would be to incorporate a model that considers jointly the decision to buy, use, and retire vehicles at the household level. As RFF posited “a household makes decisions about its vehicle ownership and use jointly: people don’t buy new vehicles or get rid of existing ones without considering how these actions will affect the use of their vehicles.”¹⁷³⁶ IPI further argued that “[i]n sum, VMT is influenced by vehicle choice and vehicle choice is influenced by VMT. And a ‘unified model of vehicle choice and usage’ is necessary.”¹⁷³⁷ While the agencies agree that a joint household consumer choice model—if one could be developed adequately and reliably to capture the myriad circumstances under which families and individuals make decisions relating to vehicle purchase, use and disposal—would reflect decisions that are made at the household level, the agencies do not agree that it is necessary, or necessarily appropriate, to model the national program at that scale in order to produce meaningful results that can be used to inform policy decisions. The most useful information for policymakers relates to national impacts of potential policy choices. No other element of this analysis occurs at the household level, and the error associated with allocating specific vehicles to specific households over the course of three decades would easily dwarf any error associated with the estimation of these effects in aggregate. The agencies have attempted to incorporate estimates of changes to the new and used vehicle markets at the highest practical levels of aggregation, and worked to ensure that these effects produce fleetwide VMT estimates that are

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

consistent with the best, current projections given our economic assumptions. While future work will always continue to explore approaches to improve the realism of CAFE/CO₂ simulation, there are important differences between small-scale econometric studies and the kind of flexibility that is required to assess the impacts of a broad range of regulatory alternatives over multiple decades. The agencies have read and evaluated the comments on the NPRM, incorporating many suggestions that improve the fidelity of this analysis—taking particular care to be conservative with the analysis. The modifications the agencies have made in response to these comments are described below (and in the RIA).

(b) *Mileage accumulation schedule*

To account properly for the average value of consumer and societal costs and benefits associated with vehicle usage under various CAFE and CO₂ alternatives, it is necessary to estimate the portion of these costs and benefits that will occur each calendar year for each model year cohort. Doing so requires some estimate of how many miles the average vehicle of each body type is expected to drive at each age. The agencies call these “mileage accumulation schedules.” For this final rule, the agencies are modifying the mileage accumulation schedules, largely in response to comments.

(i) *Data*

As mentioned in previous sections, NHTSA purchased a data set containing 70 million vehicle odometer readings from Polk in part to create the vehicle mileage accumulation schedules used in the NPRM. In the proposal, the agencies explained that Polk data was newer and believed to be qualitatively superior to the 2001 and 2009 National Household Travel Survey (NHTS) data used in prior rules.¹⁷³⁸ Consistent with previous analyses,¹⁷³⁹ the agencies used a cross-sectional sample of the Polk data for the NPRM. Cross-sectional data is like a “snapshot” in time. Rather than tracking vehicles over a period, the sample contained a single odometer reading from each vehicle sampled. In other words, the sample contained observations of the total lifetime accumulation of miles (represented by its odometer reading) through CY2015 of all MYs still present on the road. The cross-sectional sample was limited in the number of vintages included in the sample. While the sample was suitable to capture the heaviest usage ages (age zero to 15 years), it contained no observations for vehicles older than 16 years. This required the agencies to rely on mileage accumulation schedules developed from other data sources to produce annual VMT rates for older vehicles. Furthermore, in order to develop a schedule of mileage accumulation by age, it was necessary to assume that each vehicle traveled the same number of miles each year to reach its odometer reading, e.g. if a MY 2007 vehicle had an odometer reading of 88,000 in CY2015, the analysis assumed the vehicle drove 11,000 miles each year from CY2007 to CY2015.

¹⁷³⁸ See, e.g., 83 FR at 43089-90 (Aug. 24, 2018).

¹⁷³⁹ Previous rules were based on odometer data from the 2001 National Household Travel Survey (NHTS). S. Lu, “Vehicle Survivability and Travel Mileage Schedules,” Report Number: DOT HS 809 952 (January 2006).

The agencies acknowledged that this approach missed some of the nuances of car ownership.¹⁷⁴⁰ For example, vehicles are commonly part of multi-vehicle household fleets and their usage changes over time as households buy new vehicles and replace older ones. Similarly, most vehicles belong to multiple owners over the course of their useful lives, each of whom may have different patterns of usage. The most significant limitation of using cross-sectional data is the presence of an attrition bias. As a cohort ages, vehicles that have been used more heavily are more likely to be retired at each age than vehicles that are driven less. As the most heavily-driven vehicles drop out of the fleet, the remaining vehicles, which likely have been driven less at each age throughout their lives, will have lower odometer readings. Making the common, but necessary assumption that each vehicle is driven uniformly at each age results in lower miles-per-age estimates because of this attrition bias. In the schedules used for the NPRM, the effect of this bias occurred during the ages where each model year cohort typically scraps at the highest rates—9 to 15 years. These limitations led to lower estimates, which led commenters such as EDF to state “[g]iven that the Volpe Model VMT falls far short of confident measurements of gasoline consumption, these mileage accumulation schedules need to be increased.”¹⁷⁴¹ The agencies note that many of these data limitations were present in previous CAFE and CO₂ analyses.¹⁷⁴²

Several commenters noted the agencies’ reliance on cross-sectional data, and urged the use of panel data instead to develop mileage accumulation schedules. For example, API argued that cross-sectional data cannot accurately capture mileage accrual and suggested “the agencies re-consider the use of the [Polk] data for developing revised mileage accumulation schedules unless the data can capture mileage accumulation rates versus age on an individual-vehicle basis.”¹⁷⁴³ The NPRM discussed the possible use of panel data in the future and the benefits that doing so could provide.¹⁷⁴⁴

In response to these comments, the agencies created new mileage accumulation schedules based on panel data for this final rule. Unlike cross-sectional data, panel data includes a temporal element, which resolves the limitations imposed by cross-sectional data. The data source used for the final rule contains sequential readings of individual vehicles over time, and the vehicles are tracked at the VIN level. Polk accumulates readings about individual vehicles through state inspection programs, title changes, and maintenance events, among other sources. The Polk data includes observations of a specific vehicle’s odometer readings over the course of many years, capturing the accumulated lifetime mileage at multiple ages. By using the observation date and accumulated miles (represented by the odometer reading), the agencies can compute the rate of driving (miles per year, or month) between observations for each vehicle. This is a superior method to assuming that the rate of accumulation, over all ages, is simply the

¹⁷⁴⁰ See 83 FR at 43092 (Aug. 24, 2018).

ratio of odometer to age, as commenters noted. In particular, calculating the rates of mileage accumulation using successive observations of the same vehicle explicitly resolves the attrition bias and matches the approach to estimating driving rates with panel data in other studies.¹⁷⁴⁵

The panel dataset has another advantage over other sources: because it tracks individual vehicles over time, the agencies have more precise information about each vehicle's useful age. In previous analyses, the agencies were forced to assume that "age" was simply equal to the calendar year minus the model year in which the vehicle was produced. For example, a MY2010 vehicle was assumed to be five years old in 2015. This created, as API stated, a "discontinuity in the values between year 1 and year 2" within the schedules.¹⁷⁴⁶ It is common for vehicles produced in a given model year to be sold and registered over the course of multiple calendar years. Thus, a MY2010 vehicle assumed to be five years old in 2015, could have been registered for the first time in CY2012 and might have a real driving age of three years, rather than five, simply because it sat on a dealership lot for a couple of years before being purchased. The Polk data allows us to identify the first registration date of each vehicle in the sample and compute its true driving age at each point in time. This not only improves the precision of the mileage accumulation rate in the first year, but in subsequent years as well. The odometer data used in the NPRM had another limitation: odometer readings were grouped into cohorts by nameplate, for which only distributional information was available. It was necessary to use the mean odometer reading for each cohort at each age, but in cases where the distribution was skewed, the mean could be misleading. Making the same assumption about registration date, as each cohort contained information about the average registration date, further compounded the potential for distortion.

To the extent that commenters objected to the NPRM's use of Polk data on the basis of it being proprietary, the agencies note that using proprietary data is common in rulemakings, and, specifically, Polk data has been used for CAFE and CO₂ analyses on multiple occasions previously. For the 2016 final medium- and heavy-duty rule and Draft TAR, the agencies used Polk odometer data to develop the vehicle mileage accumulation schedules.¹⁷⁴⁷ Further, the specific data set was cited and is available for acquisition through Polk.

Recently, the 2017 National Household Travel Survey has become available as a possible data source to develop mileage accumulation schedules. While attractive from the standpoint of transparency, it suffers from the same flaws as data sources used to develop previous schedules. In particular, it represents a cross section of odometer readings at a single point in time, requiring the assumption that the rate of usage is simply reported odometer divided by vehicle /age, or an extrapolation of respondents' daily travel behavior into representative annual schedules, which commenters suggested was a poor assumption. Additionally, all of the odometers in the newest

¹⁷⁴⁵ See, e.g., Kenneth Gillingham, Alan Jenn, and Inês M.L. Azevedo (2015), "Heterogeneity in the Response to Gasoline Prices: Evidence from Pennsylvania and Implications for the Rebound Effect, Energy Economics," Volume 52, Supplement 1, 2015, Pages S41-S52, ISSN 0140-9883, available at <https://doi.org/10.1016/j.eneco.2015.08.011>.

¹⁷⁴⁶ API, EPA-HQ-OAR-2018-0283-5458, at 9-10.

¹⁷⁴⁷ See, e.g., 81 FR 73478, 73746 (Oct. 25, 2016); see also 81 FR 49217 (Jul. 27, 2016).

NHTS are self-reported, leading to questionable reliability of the individual data points (and notably round numbers in many cases). Finally, the NHTS is intended to be a representative sample of *households*, but not a representative sample of *vehicles*. Research has found that creating a *representative* sample of households can represent a significant challenge, as past iterations of the NHTS have systematically oversampled high income households. The nature of the sample also explicitly excludes vehicles used for commercial purposes, which nonetheless compose a meaningful portion of the new vehicle market, accumulate miles of travel, and consume fuel. The data set on which the mileage accumulation schedule used for this final rule is based contains at least two readings (and frequently several) for over 70 percent of the registered light duty vehicle population in 2016.

(ii) Methodology

The data used to construct the schedules initially included between two and fifty odometer readings from each of over 251 million unique vehicles. While most of the readings had plausible reading dates, odometer counts, and implied usage rates, some of the readings appeared unrealistic and received additional scrutiny. The agencies used a set of criteria to identify and remove readings that were likely record errors. For example, odometer readings predating the commercial release of the vehicle, showing negative VMT accumulation over time, or taken too closely together to provide meaningful insight into annual vehicle usage were removed from the analysis.¹⁷⁴⁸ Such sanitization of real datasets is typically necessary, and each step in the process was recorded and described in conformity with standard econometric practice.¹⁷⁴⁹

Similar to the NPRM, the remaining readings were sorted into five categories: cars, SUV's/vans, pickups, MDHD pickups/vans, and chassis. The car, SUVs/vans and pickup categories match the definitions used to build the VMT schedules used in the NPRM, as well as those used to build the scrappage model. [Table II-72 Table VI-152](#) shows the number of VINs, reading pairs, and average readings per VIN by body style.

Table II-~~72~~¹⁴⁵ - Summary of Polk/IHS VMT VIN and Reading Data by Body Style

Body Style	Number of VIN's Included	Number of Reading Pairs	Mean Readings per VIN
Car	92,016,334	287,512,165	4.1
SUVs/vans	66,857,117	212,656,710	4.2
Pickups	29,926,984	83,208,986	3.8
MDHD pickups/vans*	10,515,168	27,418,353	3.6
Chassis*	486,471	1,186,653	3.4

¹⁷⁴⁸ Refer to Section VI.D.1.(5).(b) of the FRIA for a full accounting of the process used to clean the Polk odometer data.

-------	-------------	-------------	-----

*Not used in this final rule analysis, in part in response to comments.

Once the dataset was cleaned, the agencies created a sample of one million reading pairs, where each pair represented an initial odometer/date reading and a subsequent odometer/date reading from the same vehicle. Analysis of the entire dataset was too computationally demanding and statistically unnecessary. Two conditions were created for sampling. The first controlled for Polk's censoring in the odometer readings recorded in the dataset (described below), and the second ensured the usage data was not biased by survival and that it represented usage rates over a relatively short period of time compatible with the beginning of the FRM analysis. Further analysis suggests that shorter periods between readings is still correlated with higher usage rates so that further filtering of the data sample was considered in the regression analysis. Once these filters were applied, the agencies considered several polynomial fits to the average odometer readings. These fits inform the final usage rates by age and body style used in this FRM analysis. The details are further described below.

One element of the usage data (mentioned above as the first condition control) required the agencies to filter the dataset. The odometer readings recorded are censored at 250k miles.¹⁷⁵⁰ For this reason, the agencies exclude readings recorded exactly as 250k miles. The censoring could bias estimates of usage rates if odometer readings and future usage rates are correlated, which they likely are. While the agencies hope to reconcile this limitation of the dataset in future work, the benefits of observing actual usage data through 30 years (rather than average odometer readings by model through 15 years) far outweigh the limitation. Still, the agencies filtered out these censored data points, since the actual odometer readings for such vehicles are likely higher than reported.

The Polk dataset is conditional on survival so that it represents the usage of vehicles on the road at the time of the sample (the end of the first quarter of 2017). In this way, it captures the actual observed usage rates of vehicles surviving to their current age in the dataset. An issue with this is that all readings of a vehicle are included in the sample. If usage rates from earlier ages and survival are correlated, which they likely are, then including the readings for a 30-year-old vehicle when it was 10 years old will bias the estimated usage rates of 10-year-old vehicles downward because vehicles that survive to advanced ages tend to be used less than vehicles that are retired at earlier ages for the same model year. As noted above, the NHTS data used in the NPRM suffered from the same problem. To mitigate this issue, the agencies applied a second filter when sampling the data set: the agencies only included readings where the reading date of the second reading in the pair is January 2015 or later. This reduces the potential bias from the joint probability of usage and survival to only those vehicles scrapped between January 2015 and

¹⁷⁵⁰ Polk codes any vehicle whose odometer exceeds 250K miles as 250K miles exactly, regardless of the actual odometer reading.

the first quarter of 2017. This balances losing information for older, less represented ages by excluding too much data on these vehicles and severely biasing the estimates of usage by age.

For estimates within the CAFE model the average usage is the relevant measure. [Table II-73](#) ~~Table VI-153~~ shows the average usage rates for cars by age as well as linear, quadratic, and cubic polynomial fits on these points.¹⁷⁵¹ The average usage rates follow a relatively smooth pattern, but appear to decline at an accelerating rate for the oldest ages. The linear equation captures this trend for older vehicles, but underestimates early ages. The quadratic fit shows a diminishing decrease in the usage of older vehicles which may overestimate their use. The cubic fit captures the early age usage trends and the accelerating decrease in the usage of older ages. For this reason, the agencies used the cubic curve as the basis for the new VMT schedules by age.

Table II-~~73~~~~446~~ - Car Averages and Predictions from Polynomial Fits by Age

Age	Averages	Linear	Squared	Cubed

13	10,500	11,043	10,763	10,690
14	10,297	10,733	10,443	10,405
15	10,197	10,423	10,129	10,129
16	9,923	10,113	9,823	9,860
17	9,715	9,803	9,524	9,597
18	9,489	9,493	9,232	9,338
19	9,212	9,183	8,948	9,081

¹⁷⁵¹ In general, the objective of a polynomial regression is to capture the nonlinear relationship between two variables. While the fit produces a nonlinear curve, it is linear in the coefficients. Choosing the lowest degree of the polynomial function that captures the inflection points in the data preserved degrees of freedom and ensures that applying the polynomial function to observations outside the range of data (as done here for ages beyond 30) is well behaved.

Table II-74 - Table VI-154 - shows the observed and predicted average usage rates by age for SUVs/vans. All the polynomial fits predict the observed average usage rates reasonably well. However, the linear fit under predicts the usage of the oldest vehicles, and the cubic fit predicts higher usage rates for vehicle ages beyond age 30. The quadratic fit predicts reasonable usage rates for all observed and out-of-sample ages through age 40. For this reason, the quadratic fit was used as the basis for the SUV mileage schedule.

Table II-75 -Table VI-155 shows the observed and predicted average usage rates for pickups by age. The observed rates initially decline at an increasing rate, the decline diminishes and appears to accelerate again for the oldest ages. The linear fit underestimates the usage rates for the youngest and oldest ages and overestimates middle-aged vehicles. The quadratic fit reasonably predicts the observed average usage rates but predicts an increase in usage rates for the oldest ages out of the observed sample. The cubic fit reasonably predicts the observed averages and appears to capture the diminishing decline of usage for the oldest ages observed in the in-sample averages. For this reason, the agencies used the cubic fit as the basis for the pickup VMT schedules.

Age	Averages	Linear	Squared	Cubed
39	NA	3,002	9,835	4,821

As in the NPRM, the current schedule differs by body-style to represent different usage profiles that the agencies observed in the data. While more stratification is possible, it is unlikely to provide much additional value. [Table II-76](#)~~Table VI-156~~ shows the annual miles driven at each age for passenger cars, SUVs (and CUVs and minivans), and pickup trucks at each age of their useful life, conditional upon surviving to that age.

Table II-~~76~~¹⁴⁹ - Comparison of NPRM and FR mileage accumulation schedules

(c) Benchmarking total VMT

In order to assess the fuel consumption and environmental impacts of regulatory alternatives, it is desirable to have a representation of aggregate travel and fuel consumption that is both reasonable and internally consistent. Some commenters suggested that the aggregate totals presented in the NPRM deviated from other published estimates, and argued that the entire analysis was therefore an unreliable source of information for decision-makers to consider. For example, EDF stated, “the NHTSA model ‘projects’ aggregate, nationwide VMT levels for 2016 and 2017 that are about 20 percent lower than formal government estimates by EIA and FHWA.”¹⁷⁵² EDF further stated, “[b]etween 2017 and 2025, fleetwide VMT grows by 3.1% per year in the Volpe Model, while it only grows 0.5% per year in the 2018 Annual Energy Outlook.”¹⁷⁵³ EDF also suggested, “[o]ne obvious way to assess the accuracy of the schedules is to compare the projections of the Volpe Model of total fleetwide fuel consumption in a recent calendar year with actual gasoline sales.”¹⁷⁵⁴

The Federal Highway Administration (FHWA) publishes annual VMT estimates for the light-duty vehicle fleet, the most recent of which is calendar year 2017. The NPRM estimate of total light-duty VMT was 2.22 trillion miles in calendar year 2016. The FHWA estimate for light duty VMT in 2016 was 2.85 trillion miles.¹⁷⁵⁵ While the definitions of light-duty are not identical in the two cases (where FHWA excludes trucks with 10,000 lbs. GVW, the agencies’ analysis excludes trucks with GVW greater than 8,500 lbs. from its light duty definition), that definitional discrepancy is not significant enough to account for the difference in the total VMT. While some commenters suggested that the agencies compare simulated fuel consumption to published estimates from EIA to determine the validity of our VMT assumptions, such a comparison requires accurate assumptions about the true on-road fuel efficiency of registered vehicles over forty model years in addition to their annual usage. Comparing simulated VMT

¹⁷⁵² EDF, Appendix A, NHTSA-2018-0067-12108, at 59.

¹⁷⁵³ EDF, Appendix B (Rykowski comments), NHTSA-2018-0067-12108, at 44.

¹⁷⁵⁴ *Id.* at 43.

¹⁷⁵⁵ See Highway Statistics 2017, Table VM-1, available at <https://www.fhwa.dot.gov/policyinformation/statistics/2017/vm1.cfm>.

directly to FHWA measurements requires fewer assumptions and is a more meaningful comparison.

Substituting the updated mileage accumulation schedules for the NPRM schedules, and using the calendar year 2016 fleet from the NPRM, produces an estimate of total light duty VMT in 2016 that is about 2.85 trillion miles—nearly identical to the FHWA estimate for 2016, despite the use of different estimation methods and data sources. FHWA’s estimate of total light-duty VMT in 2017 is 2.88 trillion miles,¹⁷⁵⁶ while the estimate produced by the simple product of the mileage accumulation schedule on the estimated on-road fleet is 2.94 trillion miles, a difference of about two percent. While not as close as the estimate for calendar year 2016, the discrepancy is still small considering that the estimates are obtained through entirely different methods. One important source of discrepancy with FHWA’s 2017 VMT estimate is the fact that the CAFE model simulation assumes all of the vehicles produced in a given model year are driven for the entire calendar year matching the vintage¹⁷⁵⁷. This means, for calendar year 2017, the initial year of the simulation used to support this rule, MY2017 vehicles are assumed to have been both registered and driven for the entirety of CY2017. As a result, it naturally overestimates the true VMT for calendar year 2017. The analysis accounts for this discrepancy by adjusting calendar 2017 total VMT downward by one percent, and the discrepancy in total VMT caused by conflating model years and calendar years dissipates over time.

While the agencies have established that the years for which they have data are sufficiently similar to published VMT estimates, the question of projection still remains. FHWA, in its forecasts of VMT (Spring 2019),¹⁷⁵⁸ forecasts a compound annual growth rate of 0.8 percent for light-duty vehicles between 2017 and 2047 in its baseline economic outlook. However, that projection uses a different set of macroeconomic conditions and fleet assumptions than this analysis. To compare CAFE model simulations of total VMT to the FHWA projections, the agencies ran the FHWA model with a comparable set of assumptions to the greatest extent possible.¹⁷⁵⁹¹⁷⁶⁰ Using similar economic growth assumptions, our reference case

¹⁷⁵⁶ *Id.*

¹⁷⁵⁷ The CAFE model uses an annual timestep, meaning that each time period represents one year. Because calendar years are (obviously) years, and all of the other inputs (discounting and inflation, macroeconomic variables, fuel prices, VMT, etc.) represent annual values, the timestep in the CAFE model is a calendar year. However, model years start prior to the calendar year for which they are named, and new model year sales continue (albeit only slightly) after their calendar year ends. In order to account for model year sales on their true timing relative to calendar years, the model would need to be restructured to use a quarterly timestep. While this would improve the fidelity between calendar year and model year for sales, obtaining quarterly projections of nearly every other variable in the analysis would be complicated (if not impossible). For this reason, the model conflates “model year” and “calendar year” for the analysis, even though it is a simplification.

¹⁷⁵⁸ See “FHWA Forecasts of Vehicle Miles Traveled (VMT): Spring 2019,” Office of Highway Policy Information, available at https://www.fhwa.dot.gov/policyinformation/tables/vmt/vmt_forecast_sum.pdf.

¹⁷⁵⁹ See “FHWA Travel Analysis Framework: Development of VMT Forecasting Models for Use by the Federal Highway Administration,” Volpe, available at https://www.fhwa.dot.gov/policyinformation/tables/vmt/vmt_model_dev.pdf.

¹⁷⁶⁰ In particular, we ran the FHWA VMT forecasting model with the same: personal disposable income, population, fuel prices (all of which come from AEO2019), and simulated on-road fleet fuel economy in the baseline.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

total light-duty VMT grows at a compound rate of 0.63 percent per year between 2017 and 2050. Using comparable assumptions in the FHWA model produce an annual growth rate of 0.66 percent. Again, these differences are remarkably low for models created with different methods, and lead to trivial variances, for the purposes of our analysis, in total VMT. The relevant annual projections for the baseline scenario appear in [Table II-77](#) -~~Table VI-157~~.

(d) *Preserving total VMT across regulatory alternatives*

In the NPRM, the combined effect of the sales and scrappage responses created small percentage differences in total VMT across the range of regulatory alternatives.¹⁷⁶¹ However, as the Environmental Group Coalition noted, even a 0.4 percent difference can result in “692 billion additional VMT under the CAFE standards and 894 billion under the CO₂ program.”¹⁷⁶² Since VMT is related to many of the costs and benefits of the program, VMT of this magnitude can have meaningful impacts on the incremental net benefit analysis. This point was made by a number of commenters who were concerned about the magnitude and direction of differences in VMT between regulatory alternatives (IPI, EDF, CBD, CARB, EPA’s Science Advisory Board).¹⁷⁶³

More generally, commenters argued that non-rebound VMT should be held constant across regulatory alternatives, regardless of the number of new vehicles sold and registered vehicles scrapped. For example, CBD commented that the “total number of VMT should be determined based on demand for travel, not arbitrarily driven by fleet size.” CARB added that fleet size can change across the alternatives “as long as the VMT schedules are adjusted to account for overall travel activity that is distributed over a larger number of vehicles.”¹⁷⁶⁴ NCAT, Global, Auto Alliance, EDF, IPI, and Honda made similar arguments.¹⁷⁶⁵

While commenters generally provided few specific recommendations about the level to which VMT should be constrained among alternatives, several of them argued that VMT projections would benefit from consideration of travel demand modeling. UCS, CBD, NCAT,

¹⁷⁶¹ The agencies explained in the NPRM that some amount of this difference was due to the rebound effect, and that “non-rebound” VMT between alternatives differed by as much as 0.4 percent. See 83 FR at 43099 (Aug. 24, 2018).

and others suggested that the overall level of light-duty VMT in a given year should reflect the broader economic context in which travel occurs.¹⁷⁶⁶ For example, Honda stated, “[i]ncreasing VMT is closely associated with increased economic activity.”¹⁷⁶⁷

The agencies agree that the total demand for VMT should not vary excessively across alternatives and stated as much in the NPRM.¹⁷⁶⁸ That said, it is reasonable to assume that fleets with differing age distributions and inherent cost of operation will have slightly different annual VMT, absent VMT associated with rebound miles; however, the difference could conceivably be small. To address these comments and to take an intentionally conservative approach, the agencies decided to constrain “non-rebound” VMT (defined more explicitly below) to be identical across regulatory alternatives in this analysis using the FHWA VMT demand model to determine the constraint; therefore, the only difference in total VMT between regulatory alternatives is the rebound miles attributable to differences in fuel economy resulting from the regulatory alternatives. Nevertheless, as explained in the NPRM and revealed in the extensive quantitative results published with the NPRM, setting aside the rebound effect, aggregate VMT as estimated in the NPRM was roughly constant across alternatives. Although differences may have appeared large in absolute terms, especially when aggregated across many calendar years and ignoring the underlying annual total quantities, the differences were nevertheless very small in relative terms—small enough to be well within the range of measurement or estimation error for virtually any of the other inputs to, or outputs of, the agencies’ analysis. It is unclear whether a 0.4 percent change in highway travel can be measured with any degree of confidence.

To constrain non-rebound VMT, the agencies needed to create a definition of non-rebound VMT and a method for calculating it. The agencies used the FHWA VMT forecasting model to produce a forecast of non-rebound VMT, to which total non-rebound VMT in every regulatory alternative is constrained in each year, regardless of the fleet size or distribution of ages in the fleet. In calendar years where total non-rebound VMT determined by the size of the fleet and assumed usage of each vehicle is lower than the constraint produced from the FHWA model, VMT is added to that total and allocated across vehicles to match the non-rebound forecast (preserving the constraint). These additional miles are then carried throughout the analysis as vehicles accrue costs and benefits. Because non-rebound VMT is being held constant for the FRM analysis across the set of regulatory alternatives in each calendar year, the only difference in VMT among the alternatives in any calendar year results from differences in fuel economy improvement relative to MY2016 that occur as a result of the standards. Finally, in subsection (D), the agencies calculate the changes in total VMT attributable to fuel economy, otherwise known as the rebound VMT.

¹⁷⁶⁶ See, e.g., NCAT, Comments, NHTSA-2018-0067-11969, at 31-32; Environmental Group Coalition, Appendix A, NHTSA-2018-0067-12000, at 175-76; and, UCS, Technical Appendix, NHTSA-2018-0067-12039, at 60-61.

(i) Defining non-rebound VMT

In order to constrain non-rebound VMT, it is first necessary to define “non-rebound VMT” more precisely. The NPRM defined the rebound effect as the overall elasticity of travel with respect to changes in the cost per mile (CPM). CPM has two components. The first component of CPM is fuel prices—the agencies expect vehicles to be driven less if fuel prices go up, all else equal. The second component of CPM is fuel economy. Therefore, the NPRM defined the percentage change in CPM, for a given scenario, model year, and calendar year, as:¹⁷⁶⁹

Equation II-7 - Full change in cost-per-mile of travel

$$\% \Delta CPM_{SN,MY,CY} = \frac{\left(\frac{FP_{CY}}{FE_{SN,MY}} - \frac{FP_{2016}}{FE_{REF}} \right)}{\frac{FP_{2016}}{FE_{REF}}}$$

Where *FP* is fuel price, *FE* is fuel economy, and *REF* refers to the reference FE value of a given age (in particular, $FE_{2016-(CY-MY)}$, which is the FE of the MY cohort that was age CY – MY in CY 2016). In the equation above, $FE_{SN,MY,CY}$ refers to the observed fuel economy of the MY cohort (typically applied at the vehicle level) for a given scenario (SN) in calendar year CY.

The CAFE model uses one value, the value specified as the rebound effect, to measure CPM elasticity. Naturally, the CAFE model produces the same magnitude of change in travel for equivalent changes in fuel prices and fuel economy. Constructing such a projection of future VMT (from 2017 to 2050) that sets aside the rebound effect required constructing inputs that were consistent with that perspective. In particular, it was necessary to separate the price response associated with the change in fuel prices relative to the year on which the agencies based the mileage accumulation schedule (end of CY2016), and the change in VMT associated with only the improvements in fuel economy, relative to MY2016, that occur for future model years at the forecasted fuel price.

As vehicles age, the agencies expect their VMT to decrease in the presence of a non-zero rebound effect if rising fuel prices over time increase the per-mile cost of travel, and the rebound effect represents the degree to which their travel is reduced for a percentage change increase in operating cost. It is intuitive that, as the cost of fuel rises over time, a vehicle with a fixed fuel economy would be driven less if gasoline costs \$3.50/gallon than it would be if gasoline costs \$2.50/gallon. Such a response is also consistent with economic principles (and literature),¹⁷⁷⁰ and so it is included in the “non-rebound” VMT that the agencies constrain across alternatives in each calendar year.

¹⁷⁶⁹ See 83 FR at 43091 (Aug. 24, 2018).

¹⁷⁷⁰ See, e.g., Goodwin, P., J. Dargay, and M. Hanly. Elasticities of road traffic and fuel consumption with respect to price and income: a review. *Transport Reviews*, 24:275-292, 2004.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Similarly, the annual mileage accumulation of cohorts in the inherited fleet is clearly affected by fuel price, but also by evolution. Setting aside any fuel economy improvements in vehicles sold and entering the on-road fleet between 2017 and 2050, the average fuel economy of each age cohort is going to improve over that period. The travel behavior of the on-road fleet was last observed through calendar year 2016 in the Polk data (discussed in (b)(ii)), when a 20-year-old car was part of the model year 1997 cohort, and had an average fuel economy of 23.4 MPG. However, the fleet continually turns over. In 2035, the 20-year-old car will be a member of the model year 2016 cohort, and have an average fuel economy of 29.2 MPG (assumed to be the average fuel economy of MY2016 vehicles when they were new).¹⁷⁷¹ If fuel prices persist at 2016 levels (in real dollars), then that 25 percent improvement in fuel economy would reduce the cost per mile of travel for 20-year-old vehicles relative to the observed values in calendar year 2016, and lead to an increase in travel demand for vehicles of that age. Importantly, this transition to more efficient age cohorts occurs in all of the regulatory alternatives. Considering only the fuel economy levels of vehicles that exist prior to the first year of simulation (2017), a secular improvement in the fuel economy of the on-road fleet would occur with no further improvements in fuel economy from new vehicles in model years 2017 to 2050. As the fleet turns over, its fuel efficiency will gradually resemble that of the model year 2016 cohort, up to the point at which each age cohort is as efficient as the model year 2016 cohort.¹⁷⁷²

The notion of “non-rebound” VMT is a construct necessary to support this regulatory analysis by controlling for VMT attributable to reasons other than rebound driving, but present only in theory. Using our symmetrical definition of rebound to represent the expected response to changes in CPM, regardless of whether those changes occur as a result of changes in fuel price or fuel economy, it is well established that demand for VMT responds to the cost of travel. To isolate the change in VMT for which the regulatory alternatives are responsible, the agencies have also included the VMT attributable to secular fleet turnover (through MY2016) in the total “non-rebound” VMT projection. In particular, this means that the conventional rebound definition used in previous analyses, is replaced in the “non-rebound” VMT estimation with a more limited definition:

Equation II-8 - Fuel price and secular improvement component of elasticity

$$\% \Delta \text{NonRbdCPM}_{MY,CY} = \frac{\left(\frac{FP_{CY}}{FE_{MIN(2016,MY)}} - \frac{FP_{2016}}{FE_{REF}} \right)}{\frac{FP_{2016}}{FE_{REF}}}$$

¹⁷⁷¹ In practice, vehicles will scrap at different rates over time, even within a body-style. Some nameplates and manufacturers have reputations for longevity and individual vehicle models with different fuel economies may seem like better candidates for repairs under particular fuel price scenarios. In light of this, the fuel economy for a given body-style will likely not continue to be the sales-weighted average fuel economy when the cohort was new, even without accounting for degradation and changes to the on-road gap over time. The agencies make this assumption here out of necessity.

¹⁷⁷² Vehicles scrap at different rates over time, and there are important differences by body style for both scrappage rates and mileage accumulation. This discussion is intended to provide intuition, without all of the computational nuance that exists in the model’s implementation.

Where FP is fuel price, FE is fuel economy, and REF refers to the reference FE value of a given age (in particular, $FE_{REF} = FE_{2016 - (CY - MY)}$, which is the average FE of the MY cohort that was age $(CY - MY)$ in CY 2016). In [Equation II-8](#)~~Equation VI-8~~, $FE_{MIN(2016,MY)}$ refers to the observed fuel economy of the model year being evaluated up to and including the 2016MY cohort. This construction explicitly accounts for the improvement in fuel economy between MY2016 and all the historical ages (through MY1977) with respect to the change in (real) fuel price relative to calendar year 2016. Thus, the VMT associated with the rebound effect in this analysis only accounts for changes to CPM that result from the amount of fuel economy improvement that occurs relative to MY2016. The full elasticity definition (in [Equation II-7](#)~~Equation VI-7~~) differs from that in [Equation II-8](#)~~Equation VI-8~~ in only one way; the fuel economy in the denominator of the first term is the fuel economy of the model year being evaluated, rather than being the minimum of the actual model year and model year 2016.

Combining this demand elasticity with the endogenously estimated vehicle population and the mileage accumulation schedule provides an initial estimate of non-rebound VMT, as in [Equation II-9](#)~~Equation VI-9~~.

Equation II-9 - Unadjusted total non-rebound VMT in a calendar year

$$NonReboundVMT = \sum_A \sum_S^{Ages\ Styles} VMT_{A,S} \cdot (1 + \% \Delta NonRbdCPM_{MY,CY} \cdot \varepsilon) \cdot Population_{CY,A,S}$$

In [Equation II-9](#)~~Equation VI-9~~, VMT represents the non-rebound mileage accumulation schedule (by age, A , and body style, S), $Population$ is the on-road vehicle population simulated by the CAFE Model (in calendar year CY , for each age, A , and body style, S), ε is the elasticity of demand for travel (the rebound effect, assumed to be -0.2 in this analysis).

However, there are factors beyond the CPM that affect light-duty demand for VMT. The FHWA VMT forecasting model includes additional parameters that can mitigate or increase the magnitude of the effect of fuel price changes on demand for VMT. In particular, the model accounts for changes to per-capita personal disposable income (and U.S. population) over time. This means that even if fuel prices are increasing over the study period (as they are in the central case), and fleetwide fuel economy improves only through fleet turnover (as it does in the simulated “non-rebound” case), total demand for VMT can still grow as a result of increases in these other relevant factors. Not only does the forecast of non-rebound VMT continue to grow in the non-rebound case, it does so at a faster rate than [Equation II-9](#)~~Equation VI-9~~ produces. Thus, in order to preserve non-rebound VMT in a way that represents expected VMT demand, the agencies must constrain non-rebound VMT in each alternative to match the forecast produced by the FHWA model using the fuel price series from the central analysis, AEO2019 Reference case assumptions for per-capita personal disposable income, and fleetwide fuel

economy values produced by simulating the effect of fleet turnover (only) in the CAFE model.¹⁷⁷³

(ii) Constraining non-rebound VMT

For this final rule, total “non-rebound” VMT is calculated for each calendar year, based on the initial starting point described above in Section (b) and a series of growth rates calculated from a forecast produced by running central analysis values through the FHWA light-duty VMT forecasting model. In any future calendar year, “non-rebound” VMT is calculated as a product of the initial CY2017 total and a series of compound growth rates:

Equation II-10 - Total non-rebound VMT constraint in each calendar year

$$\prod_{2017}^{CY} (1 + r_{CY}) \cdot TotalVMT_{2017}$$

Where *CY* is calendar year, *r* is the compound annual growth rate (unique to each *CY*), and *TotalVMT* is the calendar year total light-duty VMT estimated by the CAFE Model using the annual VMT for each body style and age in the mileage accumulation schedule (defined in [Table II-76](#)~~Table VI-156~~), the population of each age/style cohort in CY2017, and the initial difference between operating costs in 2016 and 2017. The compound annual growth rates, *r_{CY}*, in [Equation II-10](#)~~Equation VI-10~~ are derived from the inter-annual differences in the forecast of total non-rebound VMT that the agencies created using the FHWA model.

The agencies used the FHWA forecasting model to produce two distinct VMT forecasts (both of which appear in [Table II-78](#) ~~Table VI-158~~). The first of these is identical to the forecast of total VMT reported in [Table II-77](#) ~~Table VI-157~~, and represents the AEO2019 Reference case assumptions with the exception of average on-road fuel economy, which was simulated using the CAFE model to simulate new vehicle fuel economy, new vehicle sales, and vehicle retirement under the baseline standards. The forecast in the second column of [Table II-78](#) ~~Table VI-158~~ is identical to the first, except that the average on-road fuel economy accounts for only the effect of fleet turnover on fuel economy improvements (new vehicles are assumed to be only as fuel efficient as the MY2016 cohort, discussed above).

Table II-~~78~~~~451~~ - VMT projections (trillion miles)

2050	3.56	3.36	3.27	2.99

The third column is the non-rebound VMT constraint produced by the CAFE model, to which non-rebound VMT is constrained to in every regulatory alternative (under central analysis assumptions regarding fuel prices and economic growth). The non-rebound VMT constraint is

produced endogenously by the model in each run based on the estimated VMT for calendar year 2017 and a series of growth rates intended to reproduce the general growth trend in light-duty VMT under the set of “non-rebound” assumptions in the FHWA model ([Equation II-10 - Equation VI-10](#)).¹⁷⁷⁴ It differs from the “non-rebound” forecast produced by the FHWA model by one to three percent in any year. This adjustment was both an attempt to match the FHWA model’s projection of total VMT (including rebound) in the baseline, and an acknowledgment that differing levels of modeling resolution and construction are likely to produce slightly different projections. In general, the one to three percent difference in non-rebound VMT is within the range of projections based on the confidence intervals of the coefficients that define the FHWA forecasting model.

The fourth column in [Table II-78 - Table VI-158](#) represents the unadjusted “non-rebound” VMT produced by the CAFE Model using [Equation II-9](#)~~[Equation VI-9](#)~~. The reader will observe that in every calendar year, this total is lower than the non-rebound VMT constraint. This occurs because the projected fuel prices in the central analysis increase much faster than the fleetwide fuel economy (in the non-rebound case). This increases CPM and, as a consequence, reduces demand for VMT based on the price elasticity of demand for travel (rebound effect). However, the FHWA model accounts for additional variables that recognize the economic context in which this fuel price projection occurs. In particular, the model accounts for changes in the U.S. (human) population and changes to personal disposable income over the same period. These factors act to attenuate the demand response to rising fuel prices, producing a rising demand for VMT even as the CPM rises for several years.

In order to constrain non-rebound VMT to be identical in each year across regulatory alternatives, it is necessary to add VMT to the unadjusted total, endogenously calculated by the CAFE Model in each calendar year. These additional miles, denoted $\Delta miles$ for this discussion, represent the simple difference between the annual VMT constraint (column 3 of [Table II-78 - Table VI-158](#)) and the unadjusted VMT defined in [Equation II-9](#)~~[Equation VI-9](#)~~(above) in each calendar year.

Equation II-11 - Difference between VMT constraint and unadjusted non-rebound VMT

$$\Delta Miles_{CY} = VMTConstraint_{CY} - NonReboundVMT_{CY}$$

Because each regulatory scenario produces a unique on-road fleet (in terms of the number of vehicles, the distribution of ages among them, and the resulting distribution of fuel economies), the total unadjusted VMT in each calendar year (given by [Equation II-9 - Equation VI-9](#)) will be unique to each regulatory scenario. As a corollary, $\Delta miles_{cy}$ will also be unique to each regulatory scenario. By distributing $\Delta miles_{cy}$ across the vehicle fleet in each calendar year, the CAFE Model scales up the unadjusted non-rebound VMT to equal the non-rebound VMT constraint in each calendar year, for each regulatory alternative. While there are a number

¹⁷⁷⁴ This ensures internal consistency with the set of assumptions provided by the user, but can lead to differences between the non-rebound VMT constraint in the central analysis and one that is generated under a different set of assumptions (as in the sensitivity analysis, for example).

of ways to reallocate $\Delta miles_{cy}$ across the on-road fleet in order to match the non-rebound VMT constraint, the fact that unadjusted VMT is always lower suggests an obvious approach.

The primary goal of reallocation is to adjust total non-rebound VMT so that it is identically equal to the VMT constraint in every calendar year for each regulatory alternative, while conserving the general trends of the mileage accumulation schedule—which represents a good estimate of observed usage at the start of the simulation. In particular, the reallocation approach should preserve the basic ideas that annual mileage decreases with vehicle age because newer (and more efficient) vehicles are more likely to be driven additional miles than their older counterparts, and mileage accumulation varies by body style. To accomplish the reallocation, the CAFE Model computes a ratio that varies by body style, calendar year, and regulatory alternative. The ratio captures the share of additional VMT that can be absorbed by the registered vehicle population of each body style based on their relative representation in the fleet, so that per-vehicle totals across ages remain sensible (even if the distribution of body styles should change over time as the new vehicle market evolves). Then this quantity is further scaled by the total VMT for a given body style in the calendar year for which $\Delta miles$ has been computed. The resulting ratio is then used to scale the unadjusted miles from [Equation II-9](#)[Equation VI-9](#), so that the new sum of annual (non-rebound) VMT across all of the vehicles in the on-road fleet equals the constraint. For a single calendar year, CY , and a single body style, S , the scaling ratio, R , is computed as:

Equation II-12 - Calculating the scaling factor to reallocate non-rebound VMT

$$R_{S,CY} = \frac{\Delta Miles_{CY} \cdot \frac{\sum_0^{39} Population_{S,A}}{\sum_S^{styles} \sum_0^{39} Population_{S,A}}}{NonReboundVMT_{CY}}$$

In [Equation II-12](#)[Equation VI-12](#), *Population*, refers to the on-road vehicle population for a given age and body style (summed over the full range of ages in the simulation, where vehicles are modeled to survive for, at most, forty years). The fraction in the numerator calculates the fleet composition by body type.¹⁷⁷⁵ As long as the unadjusted non-rebound VMT produced by the CAFE Model is smaller than the VMT constraint for all years and regulatory alternatives (and it is), this scaling ratio allows the CAFE Model to add miles to the annual total in a way that preserves the basic ideas of the mileage accumulation schedule and achieves equality with the constraint. In particular, the total *adjusted* non-rebound VMT is then calculated as:

Equation II-13 - Total adjusted VMT that preserves non-rebound VMT constraint

¹⁷⁷⁵ We also considered basing this ratio on each body style's share of total VMT in that calendar year. However, that approach has the potential to result in allocations that add (or remove) too many miles per vehicle, depending on the age distribution and size of each body style cohort. While that approach better preserves the age distribution of VMT within a style, capturing the differences in age distribution of the population in each scenario is an objective of the VMT accounting. In testing, the differences in approach were small (about 0.1 percent difference).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

$$AdjNonRbdVMT = \sum_A \sum_S^{Ages\ Styles} NonReboundVMT_{CY,A,S} * (1 + R_{S,CY})$$

To make each alternative match the VMT constraint, [Equation II-13](#)~~Equation VI-13~~ allocates miles (in this case, adds) to each vehicle in a calendar year by multiplying the product of the mileage accumulation schedule (for that style vehicle, at that age), the %ΔNrbdCPM (described in [Equation II-8](#)~~Equation VI-8~~), and the elasticity (the rebound effect of -0.2) with the appropriate scaling ratio (defined in [Equation II-12](#)~~Equation VI-12~~). The “Allocated Miles” in [Table II-72](#)~~Table VI-152~~ are the result of this calculation for a passenger car in CY2020.

Unlike some of the accounting, which focuses on the impacts to a model year cohort of vehicles over the course of its useful life, the rebound constraint and reallocation are calendar year concepts. The constraint represents demand for VMT absent “rebound miles” (defined more explicitly above) in a specific calendar year. Thus, this reallocation occurs in every calendar year, and a vehicle of a model year cohort will likely experience many of these reallocation events during its simulated useful life. The resulting survival weighted mileage accumulation is discussed in detail in the discussion of VMT resulting from simulation found in Section (e), but an example of the annual reallocation is provided here.

In the baseline alternative, the non-rebound VMT constraint in CY2020 is about 3.068T miles, but the endogenously computed “non-rebound” VMT is only 2.955T miles. This creates a difference, Δmiles₂₀₂₀, of 112.6B miles that must be added to the total unadjusted non-rebound VMT in calendar year 2020 and allocated across the on-road fleet in that year to preserve total non-rebound VMT. Over time, this discrepancy between the FHWA model’s projection and the unadjusted total non-rebound VMT grows to about 230 billion miles. While the other classes operate identically, this example uses the reallocation that occurs to passenger cars to illustrate the mechanics of reallocation. Rising fuel prices depressing non-rebound VMT (relative to the mileage schedule) over time is a general trend that emerges for all body styles, as shown for passenger cars in [Table II-79](#) ~~Table VI-159~~.

Table II-~~79~~[79+52](#) - CY2020 passenger car VMT reallocation to preserve non-rebound constraint

The number of miles added to each age vehicle is generally less than the difference between the unadjusted non-rebound VMT (for a given age) and the mileage schedule. Thus, adding the requisite miles to each age does not distort either the shape of the schedule with age, nor does it create annual usage estimates that are out of line with observed usage. The example

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

shown here uses the baseline alternative to illustrate the reallocation of VMT in 2020, but this reallocation differs by alternative. In less stringent regulatory alternatives, new vehicles are less expensive; this increases new vehicle sales and accelerates the retirement of older vehicles (relative to the baseline). In those cases, the unadjusted non-rebound VMT is higher, Δ miles smaller, and corresponding allocation of Δ miles smaller—though still consistently positive.

Commenters encouraged us to use a demand model to avoid creating unrealistic VMT projections that failed to account for factors that exogenously influence total demand for VMT, which the agencies have done here.¹⁷⁷⁶ Had baseline case been used instead, regardless of whether it happens to be the most or least stringent alternative, as the non-rebound VMT constraint, both the non-rebound VMT and VMT with rebound would have differed meaningfully from both other government forecasts and from the projections produced by the demand models underlying those forecasts. By producing and enforcing a non-rebound constraint based on results from a travel demand model, the agencies ensure realism in the projections of total VMT under each regulatory alternative and ensure that the costs and benefits associated with rebound VMT result only from fuel economy improvements in the regulatory alternatives considered.

(e) *VMT resulting from simulation*

This section has already demonstrated that total VMT projections from the simulation are consistent with FHWA projections of total light duty VMT using the same set of economic assumptions. Lifetime mileage accumulation is now a function of the sales model, scrappage model, mileage accumulation schedules (described in [Table II-76](#)~~Table VI-156~~), and the redistribution of VMT across the age distribution of registered vehicles in each calendar year to preserve the non-rebound VMT constraint.

The definition of “non-rebound” VMT in this analysis determines the additional miles associated with secular fleet turnover and fuel price changes. Conversely, rebound miles measure the VMT difference due to fuel economy improvements relative to MY2016 (independent of changes in fuel price, or secular fleetwide fuel economy improvement resulting from the continued retirement of older vehicles and their replacement with newer ones). In order to calculate total VMT *with* rebound, the agencies apply the rebound elasticity to the full change in CPM and the initial VMT schedule, but apply the rebound elasticity to the incremental percentage change in CPM between the non-rebound and full CPM calculations to the miles applied to each vehicle during the reallocation step that ensured adjusted non-rebound VMT matched the non-rebound VMT constraint.

Equation II-14 - Total VMT with rebound miles

Ages Styles

$$\sum_A \sum_S (VMT_{A,S} \cdot (1 + \% \Delta CPM_{MY,CY} \cdot \epsilon) + \Delta Miles_{A,S,CY} \cdot (1 + (\% \Delta CPM_{MY,CY} - \% \Delta NonRbdCPM_{MY,CY}) \cdot \epsilon)) \cdot Population_{CY,A,S}$$

Where $VMT_{A,S}$ is the initial VMT schedule by age and body-style, $\% \Delta NonReboundCPM$ and $\% \Delta CPM$ are defined in [Equation II-8](#)~~Equation VI-8~~ and [Equation II-7](#)~~Equation VI-7~~, respectively, and $\Delta Miles_{A,S,CY}$ is the per-vehicle miles added by the reallocation described in [Equation II-13](#)~~Equation VI-13~~. The additional miles that are added to each vehicle in the reallocation step ($\Delta Miles_{A,S,CY}$) are multiplied by the difference between the percentage changes in CPM (full and non-rebound, respectively) because the $\% \Delta NonRbdCPM$ was used to derive the allocated miles and using the full CPM change to scale the allocated miles would count that change twice. Taking the difference avoids overestimating the total mileage in the presence of the rebound effect. The “rebound miles” will be the difference between [Equation II-14](#) ~~Equation VI-14~~ and [Equation II-10](#)~~Equation VI-10~~ for each alternative. To the extent that regulatory scenarios produce comparable numbers of rebound miles in early calendar years, the impacts associated with those miles net out across the alternatives in the benefit cost analysis.

[Table II-80](#) ~~Table VI-160~~ displays the annual survival-weighted VMT at each age of a MY2025 vehicle, by regulatory class including and reallocation needed to preserve the VMT constraint and all rebound miles (using a 20 percent rebound effect).¹⁷⁷⁷

Table II-~~80~~[453](#) - MY2025 lifetime VMT comparisons, by regulatory class

As earlier portions of this section have shown, the second decade of useful life now shows significantly higher utilization than the NPRM analysis for both passenger cars and light trucks. While the current lifetime accumulation is similar to the values produced in the 2012 final rule, those values were simulated to occur under fuel prices that were consistently 40

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

percent higher than the prices in this analysis (when adjusted for inflation).¹⁷⁷⁸ Under comparable prices, lifetime mileage accumulation would have been considerably higher.

(f) *Sales, Scrappage and VMT Integration*

The VMT construct described above, while an improvement over the version presented in the NPRM for the reasons explained, does not represent the fully integrated model of ownership, usage, and retirement decisions that some commenters argued would be preferred or even required to assess properly the impacts of CAFE/CO₂ standards. In particular, RFF commented that integrating sales, scrappage and VMT would “make the analysis internally consistent and will account for the fact that households do not make scrappage and vehicle use decisions in isolation.”¹⁷⁷⁹ IPI concurred and expanded in their comment, stating “‘a unified model of vehicle choice and usage’ is necessary.”¹⁷⁸⁰

The implication of such commenters is that the agencies have ignored important benefits of more stringent standards by not explicitly considering household decisions at the level of household vehicle fleet management. However, the opposite may be true. A recent National Bureau of Economic Research (“NBER”) paper finds that households engage in attribute substitution while managing the set of attributes in their vehicle portfolios.¹⁷⁸¹ In particular, the authors argue that attribute substitution within a household’s vehicle portfolio may erode up to 60 percent of the intended fuel economy benefits of the footprint-based CAFE/CO₂ standards, as the higher fuel economy of owned vehicles reduces demand for efficiency in the next bought vehicle, all else equal. This suggests that examining effects at the household level may not be as beneficial, or as meaningful, as some commenters might hope.

While commenters have suggested ambitious models of dynamic relationships at the household level, moreover, it is not clear that such a model is currently possible. Capturing the heterogeneous preferences of households across purchase, usage, and retirement decisions at the same level of detail required to produce meaningful estimates of regulatory compliance costs is beyond the current scope of this analysis. While the agencies agree that expected usage influences the household decision of which vehicle to purchase, how long to hold it, and how to manage the usage and retirement of other vehicles within a household fleet, the agencies do not agree that such a detailed model is a necessary prerequisite to assess the impacts of CAFE and tailpipe CO₂ emissions standards, nor that it is necessarily appropriate to do so given that the agencies are examining aggregate national fleetwide effects of such standards. Furthermore, in the most recent peer review of the CAFE Model, one reviewer remarked that while the sales and

¹⁷⁷⁸ The 2012 final rule also assumed a 10 percent rebound effect, which would have further affected lifetime mileage accumulation.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

VMT would benefit from a household choice model, “the decision to scrap a vehicle (remove it from the national in-use fleet) and the decision to purchase a new vehicle often are not made by the same household. No U.S. national-level transportation demand models (that this reviewer is aware of) tackle the issue with this level of complexity.”¹⁷⁸²

Each iteration of these regulatory analyses has endeavored to improve the accuracy and breadth of modeling to capture better the relevant dynamics of the markets affected by these policies. The agencies intend to address current limitations in future rulemakings, and meanwhile believe that the scope of the current analysis is reasonable and appropriate for informing decision-makers as to the effects of different levels of CAFE and tailpipe CO₂ emissions stringency.

(6) *What is the mobility benefit that accrues to vehicle owners?*

(a) *Mobility benefits in the NPRM analysis*

As the proposal noted, the increase in travel associated with the rebound effect provides benefits that reflect the value to drivers and other vehicle occupants of the added—or more desirable—social and economic opportunities that become accessible with additional travel. The fact that drivers and their passengers elect to make more frequent or longer trips to gain access to these opportunities when the cost of driving declines demonstrates that the benefits they gain by doing so exceed the costs they incur, including the economic value of their travel time, fuel and other vehicle operating costs, and the economic cost of safety risks drivers assume. The amount by which the benefits of this additional travel exceeds its economic costs measures the net benefits drivers and their passengers experience, usually referred to as increased consumer surplus.

Under the proposal, the fuel cost of driving each mile would have increased as a consequence of the lower fuel economy levels it permitted, thus reducing the number of miles that buyers of new cars and light trucks would drive as the well-documented fuel economy rebound effect operates in reverse.¹⁷⁸³ The agencies’ analysis of the proposed rule described the resulting loss in consumer surplus, and calculated its annual value using the conventional approximation, which is one half of the product of the increase in vehicle operating costs per vehicle-mile and the resulting decrease in the annual number of miles driven. Because the value of this loss depends on the extent of the change in fuel economy, it varied by model year, and also differed among the alternative standards that the NPRM considered.

¹⁷⁸² CAFE Model Peer Review, DOT HS 812 590, Revised (July 2019), pp. B19-B29, available at <https://www.regulations.gov/contentStreamer?documentId=NHTSA-2018-0067-0055&attachmentNumber=2&contentType=pdf>

¹⁷⁸³ Normally, the fuel economy rebound effect refers to an *increase* in vehicle use that results when increased fuel economy reduces the fuel cost for driving each mile.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The agencies' analysis specifically recognized that the economic value of any additional travel prompted by the fuel economy rebound effect must exceed the additional fuel costs drivers incur, plus the economic cost of safety risks they and their passengers assume.¹⁷⁸⁴ Thus, when vehicle use was projected to decline in response to lower fuel economy, the agencies noted that the resulting loss in benefits must have more than offset both the savings in fuel costs and the value of drivers' and passengers' reduced exposure to safety risks. In the accounting of benefits and costs for the preferred alternative, the loss of benefits associated with reduced mobility was recognized by reporting losses in travel benefits that exactly offset the value of reduced risks of being involved in both fatal and non-fatal crashes.

In addition, the accounting reported a loss in mobility benefits from reduced use of new cars and light trucks, which included a component that exactly offset the fuel savings from reduced driving, together with the loss in consumer surplus that foregone travel would otherwise have provided. Including this first component was necessary to offset the fact that the savings in fuel costs had already been recognized elsewhere in the accounting, by deducting those savings from the increase in fuel costs resulting from lower fuel economy to arrive at the reported *net* increase in fuel costs. Thus, the resulting value of the net loss in travel benefits was exactly equal to the loss in consumer surplus that any travel foregone in response to higher fuel costs would otherwise have provided.

(b) Comments on the agencies' treatment of mobility benefits in the NPRM

The agencies received only two comments referring to their treatment of mobility benefits in the analysis supporting the proposed CAFE and CO₂ standards. The California Air Resources Board (CARB) noted that the accounting of benefits and costs resulting from the proposal included losses in mobility benefits that offset the reduction in fatality costs related to the decline in new vehicle use from the fuel economy rebound effect. While CARB did not comment on the agencies' inclusion of losses in mobility benefits in their accounting, it did object to the fact that the agencies *also* reported the numerical change in fatalities that could be ascribed to the rebound effect, and considered the improvement in safety it reflected when selecting their proposed alternative.¹⁷⁸⁵ Similarly, the Institute for Policy Integrity (IPI) termed the agencies' reliance on the estimated change in the number of fatalities as partial justification for selecting their preferred alternative as arbitrary, while at the same time arguing that the reduction in driving due to the rebound effect had no net welfare impact.¹⁷⁸⁶

¹⁷⁸⁴ Although it did not attempt to estimate operating costs other than those for fuel or the value of drivers' and passengers' travel time, the benefits from any additional travel that occurs voluntarily must also at least compensate for these costs.

¹⁷⁸⁵ California Air Resources Board (CARB), NHTSA-2018-0067-11873, at pp. 121.

¹⁷⁸⁶ Institute for Policy Integrity (IPI), NHTSA-2018-0067-12213, at pp. 11. In fact, the agencies did not treat the reduction in driving as having no net impact on welfare, since as explained immediately above, the loss in consumer surplus benefits on the foregone driving was not accompanied by any offsetting cost savings. Therefore, the decline in driving in response to the rebound effect resulted in a net loss in welfare.

In response to these comments, the agencies observe that considering changes in the actual number of fatalities as well as the welfare effects of changes in drivers' and passengers' exposure and valuation of the risks of being involved in fatal crashes represents a sound approach to assessing the impacts of proposed CAFE and CO₂ standards. The safety implications of alternative future standards are clearly a legitimate and highly visible consequence for the agencies to consider when evaluating their relative merits, as are the implications of changes in the safety risks for the economic welfare of car and light truck users. Thus the agencies see no inconsistency or duplication in separately considering *both* factors as part of their assessment of alternative future standards.

(c) *Mobility benefits in the final rule*

The analysis supporting this final rule continues to treat losses in mobility benefits in the same manner the agencies previously did when analyzing the alternatives considered for the

proposed rule. Because there are several subtleties in this treatment, [Figure II-36](#) [Figure VI-61](#) is included below to clarify its details. In the figure, the demand curve shows the relationship of annual use of new cars (and light trucks), which can be thought of as their total or average annual vehicle-miles driven, to the cost per mile of driving.

Figure II-3667 - Treatment of Mobility Benefits from Reduced Driving

The initial cost per mile OC_0 consists of the per mile economic costs of the risks of being involved in fatal and non-fatal crashes, shown by the heights of Og and gd on the vertical axis, together with per-mile fuel costs at the baseline level of fuel economy, the height of segment

dC_0 .¹⁷⁸⁷ Annual miles driven at this initial per-mile cost are shown by the distance OM_0 on the horizontal axis in ~~Figure II-36~~~~Figure VI-61~~. When fuel economy declines from its baseline level under one of the regulatory alternatives considered, fuel costs per mile increase from dC_0 to dC_1 , but the per-mile economic costs of crash risks (both fatal and non-fatal) are unaffected, so total costs per mile driven rise to OC_1 . In response to this increase in the per-mile fuel and total cost of driving, annual use declines to OM_1 .

The resulting loss in total benefits when vehicle use declines from OM_0 to OM_1 is the trapezoidal area M_1acM_0 , but most of this loss is offset by cost savings from reduced driving, so the net welfare loss is considerably smaller. Specifically, the rectangle M_1hiM_0 represents a reduction in the total economic costs of the risk that drivers and passengers will be involved in fatal crashes when the decline in driving reduces their exposure to that risk. The dollar value of this area thus appears in the agencies' accounting of costs and benefits as *both* a benefit from that reduction in risk and an exactly offsetting loss in benefits from reduced mobility. The same is true of the rectangle $hefi$, the dollar value of which corresponds to both the reduction in the economic cost of non-fatal crash risks and an identical loss in mobility benefits.

Total fuel costs for driving OM_0 miles are initially the rectangular area dC_0cf , and the decline in driving to OM_1 that results as per-mile fuel and total driving costs rise changes total fuel costs to the rectangle dC_1ae . Because these two areas share rectangle dC_0be , the *net* change in fuel costs reported in the agencies' accounting consists of the dollar value of rectangle C_0C_1ab , minus that of rectangle $ebcf$. The economic value of the loss in mobility benefits the agencies report in their accounting is the trapezoid $eacf$, but part of that area consists of rectangle $ebcf$, and is thus exactly equal to the savings in fuel costs from reduced driving. Since this savings has been already incorporated in the reported change in total fuel costs, and it offsets part of the reported loss in mobility benefits, leaving only the loss in consumer surplus that travelers would otherwise have experienced on foregone reduced driving, the value of triangle bac , as the net loss in mobility benefits.¹⁷⁸⁸

This discussion assumes that drivers correctly estimate and consider—or “internalize”—the risks of being involved in both fatal and non-fatal crashes that are associated with their additional driving. However, as is noted in the discussion of the potential effects of the rule on the mass of vehicles and its resulting impact on safety, consumers may value safety risks imperfectly. This possibility is accounted for in the final rule analysis by assuming the portion of the added safety risk that consumers internalize to be 90 percent. In ~~Figure II-36~~~~Figure VI-61~~ above, this would be reflected by including a total social cost per mile that is higher than the C_0 and C_1 values for the baseline and reduced MPG cases shown in the graphic by 10 percent of the combined cost of fatal and non-fatal crash risks (the distance Od on the figure's vertical axis), while reducing the costs of safety risks that drivers do consider to 90 percent of the values shown. The higher social

¹⁷⁸⁷ Per-mile fuel costs are equal to the dollar price of fuel per gallon, divided by fuel economy in miles per gallon. For simplicity, this figure omits non-fuel operating costs, vehicle maintenance and depreciation, and the value of occupants' travel time. Including them would not change the analysis.

¹⁷⁸⁸ Thus the change in driving is not welfare-neutral, as IPI asserted in the comment cited previously; instead, it results in a net loss in welfare.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

costs would offset a portion of the consumer surplus associated with additional mobility (in each case), and result in a small “deadweight loss” over the region where the social cost of driving exceeds the demand curve. These impacts are also fully accounted for in the final rule analysis.

(7) *What is the sales surplus that accrues to vehicle owners?*

Buyers who would not have purchased new models with the baseline standards in effect but decide to do so in response to the changes in new vehicles’ prices with less demanding standards in place will also experience increased welfare. Collective benefits to these “new” buyers are measured by the consumer surplus they receive from their increased purchases.

At the proposed rule stage, the agencies elected to exclude the consumer surplus associated with new vehicle purchases because “it is not entirely certain that sales of new cars and light trucks [would] increase in response to [the] proposed action.”¹⁷⁸⁹ Consumer surplus is a fundamental economic concept and represents the net value (or net benefit) a good or service provides to consumers. It is measured as the difference between what a consumer is willing to pay for a good or service and the market price. OMB circular A-4 explicitly identifies consumer surplus as a benefit that should be accounted for in cost-benefit analysis. For instance, OMB Circular A-4 states the “net reduction in total surplus (consumer plus producer) is a real cost to society,” and elsewhere elaborates that consumer surplus values be monetized “when they are significant.”¹⁷⁹⁰

The decision to exclude consumer surplus for new vehicles at the proposed rule stage was an error and inconsistent with OMB’s guidance on regulatory analysis. The agencies are confident that lower vehicle prices, holding all else equal, should stimulate new vehicle sales and by extension produce additional consumer surplus. That preliminary decision was also inconsistent with other parts of the agencies’ analysis. For instance, the agencies calculate the lost consumer surplus associated with reductions in driving owing to the increase in the cost per mile in less stringent regulatory cases, as discussed in section VI.D.1.b.9. The surpluses associated with sales and additional mobility are inextricably linked as they capture the direct costs and benefits accrued by purchasers of new vehicles. The sales surplus captures the savings to consumers when they purchase cheaper vehicles and the additional mobility measures the cost of higher operating expenses. It would be inappropriate to include one without the other.

The shaded area in [Figure II-37](#)~~Figure VI-62~~ reflects the consumer surplus calculated for new vehicle sales. Line C_0 reflects the baseline vehicle cost. The final rule is expected to reduce the cost of light duty vehicles, as represented by dotted line C' . Consistent with other sections of the analysis, the agencies assume that consumers value 30 months of fuel savings. Under the final rule, consumers are expected to experience higher fuel costs than they would under the

¹⁷⁹⁰ OMB Circular A-4, at 37-38.

baseline scenario, shifting costs from line C' to line C_I . The consumer surplus is equal to the area under the curve between Q_0 and Q_I .¹⁷⁹¹

Figure II-3768 – New Vehicle Consumer Surplus Net of Increased Fuel Costs]

(8) *Implicit opportunity cost*

The agencies' central analysis assumes the selling price for new vehicles will be reduced to fully reflect manufacturers' savings in technology costs for complying with less stringent CAFE and CO₂ emission standards. Specifically, new car and light truck prices are assumed to decline by the average savings in technology costs per vehicle that manufacturers would realize from complying with the standards this rule establishes, instead of with the more demanding baseline standards. The agencies' analysis assumes that under these final standards, attributes of new cars and light trucks *other than fuel economy* would remain identical to those under the baseline standards, so that changes in sales prices and fuel economy would be the only sources of benefits or costs to new car and light truck buyers. Furthermore, the agencies recognize that buyers may have time preferences that cause them to discount the future at higher rates than the agencies are directed to consider in their regulatory evaluations. In either case, the agencies' central analysis may overstate both the net private and social benefits from adopting more stringent fuel economy and CO₂ emissions standards. For instance, Table I-97 [Combined LDV Societal Net Benefits for MYs 1975-2029, CAFE Program, 7 percent Discount Rate] shows that the CAFE final rule would generate \$16.1 billion in total social net benefits using a 7 percent

¹⁷⁹¹ The exact calculation is $0.5 \times \text{the increase in sales} \times \text{the reduction in the cost of light duty vehicles net of the increased fuel cost}$.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

discount rate, but without the large net private loss of \$26.1 billion, the net social benefits would equal the external net benefits, or \$42.4 billion. Therefore, given that government action cannot improve net social benefits absent a market failure, if no market failure exists to motivate the \$26.1 billion in private losses to consumers, the net benefits of these final standards are \$42.2 billion.

To explore further the possibility that the central analysis is incomplete regarding the consumer benefits of other vehicle attributes, the agencies conducted a sensitivity analysis using a conservative estimate of this value. In the proposal, the agencies considered the lost value of other vehicle attributes in two sensitivity cases that reduced the total consumer benefit.¹⁷⁹² The agencies received several comments suggesting that the analysis of other vehicle attributes lost could be improved. For example, CARB commented that the “analyses do not adequately model how vehicle values will change in response to improving fuel economy, or the competing effects of other attributes.”¹⁷⁹³ In response to commenters, the agencies have revised their sensitivity analyses to model better the impact of the standards on other vehicle attributes.

The agencies considered, such as they did in the proposal, offsetting the net private costs associated with enabling more choices in fuel-saving technologies in a manner similar to rebound driving. However, the agencies believe that this approach is unnecessary, as such an analysis would produce nearly identical net benefits to the external net benefits—which the primary analysis already generates. Furthermore, given that consumers are free to choose more fuel-efficient vehicles absent more stringent regulations, applying the rational consumer logic from above suggests that consumers who prefer certain vehicle attributes instead of fuel economy necessarily value those attributes *more* than the fuel efficiency technologies they voluntarily forgo. As such, a sensitivity analysis including a value for other vehicle attributes should more than offset the net private costs to consumers from the primary analysis.

For the final rule, instead of keeping the same approach as the preliminary analysis, the agencies have elected to estimate consumer benefits of other vehicle attributes in a sensitivity case using similar logic to that used for the sales and scrappage models. In those models, the agencies assume that consumers value thirty months of undiscounted fuel savings. Given this assumption, it would be reasonable for the agencies then to assume that the value of other vehicle attributes must be greater than the fuel savings for the remaining term of the useful life of the vehicle—as these are fuel economy savings that consumers are clearly willing to forgo. The agencies acknowledge that vehicles are typically sold more than once, but evidence suggests that fuel savings are capitalized into sales prices in the used car market.¹⁷⁹⁴ If this is the case, new car purchasers would internalize the additional value on resale owing to fuel efficiency technologies, and the fuel savings over the remaining useful life less thirty months would be an appropriate value to use for the value of other vehicle attributes. Nevertheless, the agencies have

¹⁷⁹² See PRIA at 954. See also, PRIA at 1539.

¹⁷⁹³ CARB, Detailed Comments, NHTSA-2018-0067-11873 at 189.

¹⁷⁹⁴ For further discussion of the evidence, see section VI.D.2 of the preamble.

ected to be conservative and, instead, opted to use the fuel savings over the first seventy-two months (less the first thirty months), which approximates the amount of time the first owner typically holds a new vehicle.¹⁷⁹⁵ This value is referred to as the “implicit opportunity cost” of forgoing other vehicle attributes in favor of increased fuel economy (or using their scarce financial resources to invest in savings or the purchase of other goods that they prefer more than fuel economy),¹⁷⁹⁶ showing a cost savings for less stringent alternatives.¹⁷⁹⁷ Unlike the sales surplus, which measures the consumer surplus of new vehicle buyers entering the market, the implicit opportunity cost contained in this sensitivity case represents the forgone benefits to consumers the model assumes would have purchased a vehicle regardless of the standards (but would prefer to take the upfront cost of fuel economy technologies and invest that money elsewhere, whether it be on different vehicle attributes or different goods altogether). These results are shown in Tables VII-107 through VII-110 [Combined LDV Societal Net Benefits (Accounting for Implicit Opportunity Cost) for MYs 1975-2029 CAFE Program, 3 percent Discount Rate and 7 percent Discount Rate, as well as the CO₂ Program, 3 percent Discount Rate and 7 percent Discount Rate].

The agencies note that the central analysis of the final rule features a conservative treatment of private benefits and costs that may bias the results in the favor of more stringent regulatory alternatives. This bias arises from the agencies’ treatment of rebound driving. The agencies assume that drivers make a rational decision when electing to drive additional miles, which considers not only the risks the additional driving poses to their own lives and property, but also most of the risks their behavior poses to their passengers as well as the person and property of other road users. In such a case, drivers “internalize” most of these risks, and it can be assumed that benefits to drivers must be more valuable to them than the risks they considered when deciding whether to undertake the additional driving. Therefore, the agencies have appropriately offset the loss in safety benefits, which are associated with the increased cost of driving in the final rule, with commensurate lost benefits of additional driving.

¹⁷⁹⁵ There are several reasons why 72 months is an appropriate approximation. According to a report from the Federal Reserve bank of Chicago the average new vehicle is owned for over 77 months as of 2015. From the same report, the average new car financing term was over 67 months in 2016. (<https://www.chicagofed.org/publications/working-papers/2019/2019-04>; accessed: December 23, 2019). Data from R.L. Polk suggest that the average new car is held for 71.4 months (as cited in <https://www.autotrader.com/car-shopping/buying-car-how-long-can-you-expect-car-last-240725>). State Comptrollers and Treasurers referred to an IHS Markit report that the average length of time a consumer keeps a new car is approximately 6.6 years (78 months). EPA-HQ-OAR-2018-0283-4153, at 2. CFA commented that new vehicle leases are running, on average, 68 months and new vehicles are being held, on average, longer than 60 months. Comments, NHTSA-2018-0067-12005, at 76. The agencies selection of 72 months is comfortably within the range of these estimates, but errs towards the lower-end and therefore provides a conservative estimate.

¹⁷⁹⁶ These vehicle attributes may include any that consumers may value and are not explicitly modeled to be neutral across regulatory alternatives. For instance, trim levels, entertainment systems, crash avoidance technologies, etc. may be sacrificed to pay for higher fuel economy technology levels.

¹⁷⁹⁷ The implicit opportunity cost must be considered a value that consumers place on other vehicle attributes that is net of the cost of those attributes. This is the forgone consumer surplus of other vehicle attributes. As such it is appropriately additive to the technology cost/savings estimated in the primary analysis.

In contrast, the agencies can be *assured* the private benefits and costs of fuel saving technologies (aside from the external environmental damages) are internalized—as there is no doubt that the owners of the vehicles will accrue the fuel costs/savings. The agencies believe it would be entirely contradictory to assert that consumers are rational, informed, and considerate enough to internalize the risks of additional driving to themselves, their passengers, as well as other drivers and passengers; but are not similarly rational and informed enough to consider the additional fuel costs of purchasing a vehicle without a particular fuel-saving technology. After all, existing regulations require that the estimated annual fuel costs of a vehicle are disclosed *on the new vehicle a consumer intends to purchase*—and no such disclosure exists for the risks associated with driving a rebound mile. The agencies’ decision to offset rebound miles, but not net private costs stemming from enabling more choices in fuel-saving technologies, significantly favors more stringent alternatives.

Another possibility, however, is that manufacturers could redirect some or all of their savings in technology costs to instead improve other attributes of cars and light trucks – passenger comfort, safety, carrying and towing capacity, or performance – that potential buyers value. For example, they could redeploy the energy efficiency improvements from some technologies that would otherwise have been used to increase fuel economy to instead improve vehicles’ performance, or redirect spending on fuel economy technology to improve safety or interior comfort. Producers could also offer combinations of price reductions and more limited improvements in these other attributes on some of their models, while continuing to offer high levels of fuel economy on other models, and channeling their entire cost savings into price reductions on yet other vehicles. Individual manufacturers would presumably select different combinations of these strategies, each in an effort to realize maximum additional sales and profits.

The agencies’ analysis does not quantify specific improvements in other attributes manufacturers could make, or identify potential combinations of lower prices and improvements in other attributes they might offer when they face less demanding fuel economy and CO₂ standards. Nevertheless, there is ample empirical evidence that tradeoffs among fuel economy and other attributes that buyers value are important considerations in vehicle design and marketing strategy, and that manufacturers commonly offer combinations of both higher fuel economy and improvements in other attributes when standards do not require them to focus exclusively on improving fuel economy.

Table 1 summarizes empirical estimates of the tradeoffs among fuel economy, horsepower (for cars) or torque (for light trucks), and weight derived from different authors’ econometric estimates of the “curvature” of technology frontiers for cars and light trucks. Such frontiers describe the combinations of fuel economy and other attributes that manufacturers can provide with different levels of spending on vehicle design and technology, accounting for the gradual improvements in technology and energy efficiency that occur over time. The entries in the table show different authors’ estimates of the percent increases in horsepower, torque, and

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

weight that car and light truck manufacturers could *instead* achieve if they reduced fuel economy by one percent. (Although increased weight is not desirable in and of itself, it is associated with features such as a vehicle's passenger- and cargo-carrying capacity, interior volume, comfort, and safety, which potential buyers do value.) It is important to note that these tradeoffs apply to the overall average values of each attribute for cars and light trucks produced during recent model years, rather than to the features of specific individual models.

Table II-81+54 – Estimated Tradeoffs among Fuel Economy and Other Attributes of Cars and Light Trucks

Source	Vehicle Class	% Increase in Other Attributes per 1%		
		Horsepower	Torque	Weight
Klier and Linn	Cars	0.24%	--	0.34%
	Light Trucks	--	0.16%	0.36%
Knittel	Cars	0.26%	0.08%	0.39%
	Light Trucks	0.06%	0.31%	0.36%

For example, Table 1 shows that Klier & Linn estimate reducing the average fuel economy of cars by 1% would enable producers to increase their average horsepower by 0.24%, and Knittel's estimate of that tradeoff is very similar (0.26%). Similarly, those two studies estimate that reducing the average fuel economy of cars and light trucks by 1% would enable their weight to be increased by 0.34-0.39%, which would in turn enable manufacturers to make modest improvements in their passenger- and cargo-carrying capacity, interior volume, comfort, or safety. (Note that reducing average fuel economy by 1% would permit either power *or* weight to increase as indicated in the table, but *not* both at the same time.)

The tradeoffs summarized in Table 1 provide some indication of changes in attributes other than fuel economy that manufacturers are likely to offer under the less demanding CAFE and CO₂ standards. For example, the agencies estimate that the baseline CAFE standards would have required increases in fuel economy approximately 5% annually over model years 2020-26 for cars, while this rule reduces the required rate of increase to 1.5% annually. This less demanding standard would thus enable producers to accompany higher fuel economy with significant improvements in other features that new car buyers also value, as an alternative to simply reducing prices to reflect their savings in technology costs. As noted previously, they would do so only if they thought such a strategy would be more attractive to buyers, so the agencies' estimates of benefits to new car and light truck buyers represents the minimum improvement in utility they would realize.

The historical evolution of car and light truck characteristics under CAFE standards may also provide some indication about how manufacturers are likely to respond to the less aggressive standards this rule establishes. Figures 1 and 2 show that during the period when

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

CAFE standards remained unchanged or increased slowly – approximately 1985-2010 – manufacturers gradually improved cars’ and light trucks’ average fuel economy as well as their power (or torque) and weight, while only modestly increasing the average interior volume of cars.

Figure II-3869 – Historical Evolution of Car Attributes under CAFE Standards

Figure II-3970 – Historical Evolution of Light Truck Attributes under CAFE Standards

Table 2 summarizes the rates of change in fuel economy and other attributes of cars and light trucks over that period. As it shows, most advances in cars' drive train technology were used to increase power and fuel economy, while most of the improvement in light trucks' energy efficiency was channeled into higher torque and weight, with relatively little used to improve fuel economy.

Table II-82455 – Annual Rates of Change in Car and Light Truck Attributes under CAFE Standards

Regulatory Class	Period of Approximately Flat Standards	Compound Annual % Increases					
		Actual MPG	Horse-power	Torque	Weight	Interior Volume	Potential MPG
Passenger Cars	1985-2010	0.83%	2.17%	--	0.53%	0.07%	1.56%
Light Trucks	1984-2004	0.21%	--	3.54%	1.21%	--	1.48%

The last column of Table 2 combines the actual historical rates of increase in attributes other than fuel economy with the tradeoffs between fuel economy and other attributes shown previously in Table 1 to estimate the annual rates of increase in fuel economy that could have been achieved if all technological progress had been channeled into improving fuel economy. As it indicates, manufacturers could have increased the fuel economy of both cars and light trucks

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

over the period spanned by Table 2 at almost exactly the 1.5% annual rate this rule requires, if they had believed that sacrificing other improvements in the interest of achieving higher fuel economy was the most effective strategy to meet potential customers' demands.

While this result should be regarded as illustrative, it appears to show that meeting even these relaxed standards may require manufacturers to focus on improving fuel economy instead of other vehicle attributes. It also suggests that meeting the more demanding baseline standards may have required manufacturers to make significant sacrifices in other attributes, rather than simply holding those other features at or near their current levels. Viewed from this perspective, while this rule might not enable manufacturers to improve other desirable features of cars and light trucks at the same time as they provide the improvements in fuel economy it requires, it may nevertheless prevent them from having to sacrifice other improvements that buyers regard as valuable in order to focus solely on complying with more demanding CAFE and CO₂ standards.

(9) *Refueling benefit*

Increasing CAFE/CO₂ standards, all else being equal, affect the amount of time drivers spend refueling their vehicles in several ways. First, they increase the fuel economy of ICE vehicles produced in the future and, consequentially, decrease the number of refueling events for those vehicles. Second, given increased production costs, they reduce sales of new vehicles and scrappage of existing ones, causing more VMT to be driven by older and less efficient vehicles which require more refueling events for the same amount of VMT driven. Finally, they may change the number of electric vehicles that are produced, and shift refueling to occur at a charging station, rather than at the pump—changing per-vehicle lifetime expected refueling costs. While there are multiple ways that fuel economy standards alter refueling costs, the proposal accounted for only the first. Before the inclusion of the sales and scrappage models, which first appeared in the NPRM analysis for the first time a CAFE/ CO₂ rulemaking, the agencies did not have the means to capture the other two effects. While the agencies modeled sales and scrappage effects, they did not extend the results to refueling time. This oversight was noted by commenters, and the final rule model now includes these additional factors. The basic calculation for all three effects is the same: the agencies multiply the additional amount of time spent refueling by the value of time of passengers, which is assumed to be the same for all three effects.

(a) *Value of Time*

The calculation of the value of time remains relatively unchanged from the proposal and follows the guidance from DOT's 2016 *Value of Travel Time Savings* memorandum ("VTTS Memo").¹⁷⁹⁸ The economic value of refueling time savings is calculated by applying valuations

¹⁷⁹⁸ United States Department of Transportation, The Value of Travel Time Savings: Departmental Guidance for Conducting Economic Evaluations, (2016), available at <https://www.transportation.gov/sites/dot.gov/files/docs/2016%20Revised%20V>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

for travel time savings from the VTTS Memo to estimates of how much time is saved across alternatives.¹⁷⁹⁹

IPI commented that the agencies used old data to calculate the refueling benefit in the proposal. Specifically, IPI pointed out that the data used in the proposal seemed “to come from the 2003 version of [the VTTS Memo].”¹⁸⁰⁰ For the final rule, the analysis uses the most recent VTTS memo along with updated wages. The value of travel time depends on average hourly valuations of personal and business time, which are functions of annual household income and total hourly compensation costs to employers. As designated by the 2016 VTTS memo, the nationwide median annual household income, \$56,516 in 2015, is divided by 2,080 hours to yield an income of \$27.20 per hour. Total hourly compensation cost to employers, inclusive of benefits, in 2015\$ is \$25.40.¹⁸⁰¹ Table II-83Table VI-161 demonstrates the agency’s approach to estimating the value of travel time (\$/hour) for both urban and rural (intercity) driving. This approach relies on the use of DOT-recommended weights that assign a lesser valuation to personal travel time than to business travel time, as well as weights that adjust for the distribution between personal and business travel.¹⁸⁰² In accordance with DOT guidance, wage valuations are estimated with base year 2015 dollars and end results are adjusted to 2018 dollars.

Table II-83+56 - Estimating the Value of Travel Time for Urban and Rural (Intercity) Travel (\$/hour, 2015 Dollars)

Urban Travel			
	Personal Travel	Business Travel	Total
Wage Rate (\$/hour)	\$27.20	\$25.40	-
DOT - Recommended Value of Travel Time Savings, as % of Wage Rate	50%	100%	-
Hourly Valuation (=Wage Rate * DOT-Recommended Value)	\$13.60	\$25.40	-
% of Total Urban Travel	95.4%	4.6%	100%
Hourly Valuation (Adjusted for % of Total Urban Travel)	\$12.97	\$1.17	\$14.14
Rural (Intercity) Travel			
	Personal Travel	Business Travel	Total
Wage Rate (\$/hour)	\$27.20	\$25.40	

¹⁷⁹⁹ VTTS Memo Tables 1, 3, and 4.

¹⁸⁰⁰ IPI, Appendix, NHTSA-2018-0067-12213, at 51.

¹⁸⁰¹ *Ibid* at 11.

¹⁸⁰² Business travel is higher than personal travel because an employer has additional expenses, *e.g.* taxes and benefits costs, above and beyond an employee’s hourly wage. In the proposal, the agencies erroneously used the same value for personal and business travel, which was inconsistent with the VTTS Memo.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Urban Travel			
DOT - Recommended Value of Travel Time Savings, as % of Wage Rate	70%	100%	
Hourly Valuation (=Wage Rate * DOT-Recommended Value)	\$19.04	\$25.40	
% of Total Rural Travel	78.6%	21.4%	100%
Hourly Valuation (Adjusted for % of Total Rural Travel)	\$14.97	\$5.44	\$20.40

Estimates of the hourly value of urban and rural travel time (\$14.14 and \$20.40, respectively) shown in [Table II-83](#)~~Table VI-161~~, must be adjusted to account for the nationwide ratio of urban to rural driving.¹⁸⁰³ This adjustment, which gives an overall estimate of the hourly value of travel time—independent of urban or rural status—is shown in [Table II-84](#)~~Table VI-162~~.

Table II-~~84~~¹⁵⁷ - Estimating Weighted Urban/Rural Value of Travel Time (\$/hour, 2015 Dollars)

	Unweighted Value of Travel Time (\$/hour)	Weight (% of Total Miles Driven)	Weighted Value of Travel Time (\$/hour)
Urban Travel	\$14.14	69.9%	\$9.89
Rural Travel	\$20.40	30.1%	\$6.14
Total	-	100.0%	\$16.03

Note that the calculations above consider the value of travel time for only one occupant. To estimate fully the average value of vehicle travel time per vehicle, the agencies must account for the presence of all additional passengers during refueling trips. The agencies estimated average vehicle occupancy using survey data gathered as part of our 2010-2011 National Automotive Sampling System's Tire Pressure Monitoring System (TPMS) study.¹⁸⁰⁴ The study was conducted at fueling stations nationwide and researchers made observations regarding a variety of characteristics of thousands of individual fueling station visits from August, 2010 through April, 2011. Among these characteristics of fueling station visits, the total number of occupants per vehicle were observed. Average vehicle occupancy was calculated and multiplied

¹⁸⁰³ Estimate of Urban vs. Rural travel weights from FHWA December 2018 Traffic Volume Trends, Monthly Report, Table 2 - Cumulative Monthly Vehicle-Miles of Travel in Billions. Available at https://www.fhwa.dot.gov/policyinformation/travel_monitoring/18dectvt/page3.cfm.

¹⁸⁰⁴ Docket for Peer Review of NHTSA/NASS Tire Pressure Monitoring System, available at <https://www.regulations.gov/docket?D=NHTSA-2012-0001>

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

by the value of travel time per occupant. As shown in ~~Table II-85~~~~Table VI-163~~, this adjustment is performed separately for passenger cars and for light trucks, yielding occupancy-adjusted valuations of vehicle travel time during refueling trips for each fleet. Lastly, the occupancy-adjusted value of vehicle travel time is converted to 2018 dollars using the GDP deflator as shown in ~~Table II-86~~~~Table VI-164~~.¹⁸⁰⁵

Formatted: Check spelling and grammar

Table II-~~85~~~~58~~ - Estimating the Value of Travel Time for Light-Duty Vehicles (\$/hour, 2015 Dollars)

	Passenger Cars	Light Trucks
Average Vehicle Occupancy During Refueling Trips (persons)	1.21	1.23
Weighted Value of Travel Time (\$/hour)	\$16.03	\$16.03
Occupancy-Adjusted Value of Vehicle Travel Time During Refueling Trips (\$/hour)	\$19.39	\$19.71

Table II-~~86~~~~59~~ - Value of Vehicle Travel Time in 2018 Dollars (\$/hour, 2018 Dollars)

	Passenger Cars	Light Trucks
Occupancy-Adjusted Value of Vehicle Travel Time During Refueling Trips (\$/hour)	\$20.45	\$20.79

IPI commented that the exclusion of children from the NPRM’s refueling time analysis was inconsistent with DOT’s 2016 *Value of Travel Time Savings* memorandum (“VTTS Memo”). IPI claimed that the VTTS Memo “consider[ed] whether the value of travel time is different for parents versus children, but ultimately conclude[d] that ‘it must be assumed that all travelers’ VTTS are independent and additive.’” IPI also quoted language from page 13 of the VTTS Memo that “[a]lthough riders may be a family with a joint VTTS or passengers in a car pool or transit vehicle with independent values, these circumstances can seldom be distinguished [...] therefore, all individuals are assumed to have independent values,” and that it is “inappropriate to use different income levels or sources for different categories of traveler.”¹⁸⁰⁶

¹⁸⁰⁵ Bureau of Economic Analysis, NIPA Table 1.1.9 Implicit Price Deflators for Gross Domestic Product, available at https://apps.bea.gov/iTable/index_nipa.cfm.

¹⁸⁰⁶ See IPI, Appendix, NHTSA-2018-0067-12213, at 52-53 (citing United States Department of Transportation (“DOT”), The Value of Travel Time Savings: Departmental Guidance for Conducting Economic Evaluations, (2016), available at <https://www.transportation.gov/sites/dot.gov/files/docs/2016%20Revised%20V>).

IPI further asserted that excluding passengers under age 16 from the calculation of travel time savings was inconsistent with the best practices of benefit-cost analysis. IPI noted that Circular A-4 does not distinguish between children and adults except when monetizing health effects. IPI then cited Dale Whittington and Duncan MacRae as stating “there is a clear consensus that children should be counted in cost-benefit analysis.” Finally, IPI commented that Congress intended that the agencies consider the economic impact to children when setting standards.¹⁸⁰⁷

The agencies point out that the first passage from the VTTS Memo cited by IPI does not conclude, or even deliberate, that the VTTS of children is the same as adults, but instead states that the VTTS of children, parents and other passengers should be independent and additive.¹⁸⁰⁸ Assuming that the opportunity cost of children’s time is zero is compatible with this practice. Likewise, IPI concluded from the text on page 12 that it was inappropriate to use different incomes for children. However, IPI’s analysis suffers from two errors.

First, the two quotes from page 12 reside in a section of the VTTS Memo entitled *Special Issues*, which provides guidance on three distinct topics. The first quoted text comes from a paragraph advising how to treat vehicles with multiple passengers, while the second is from an ensuing topic about passenger incomes. It is baseless to assume that the conclusion of the second topic holds true for the first.

Second, assuming IPI intended to comment that age is a “category of traveler” for which “it is inappropriate to use different income levels,” the agencies note that such an interpretation is tenuous. The VTTS Memo clearly recognizes that some categories of travelers should have different levels of income,¹⁸⁰⁹ and provides two examples.¹⁸¹⁰ As children are not part of the workforce, they do not have wage incomes. Therefore, it is not wild speculation that they do not bear a financial opportunity cost associated with their time spent in vehicles during refueling.¹⁸¹¹ As such, excluding children from the calculation of the refueling benefit is consistent with DOT’s guidance.

Turning to IPI’s comments on best practices and Congress’ intent, the agencies agree that the benefit-cost analysis should include children when appropriate. The majority of the components of the CAFE model (e.g., safety analyses) include children. However, children are excluded from the analysis when it is appropriate (e.g. employment). For this specific valuation,

¹⁸⁰⁷ See IPI, Appendix, NHTSA-2018-0067-12213, at 53-54 (internal citations omitted).

¹⁸⁰⁸ See VTTS Memo at 5.

¹⁸⁰⁹ The full text quoted by IPI reads, “[e]xcept for specific distinctions, we consider it inappropriate to use different income levels or sources for different categories of traveler.” VTTS Memo at 12 (emphasis added). The VTTS Memo further contemplates that it is appropriate to assign different incomes if “estimates [of income are] derived by reliable and focused research [...] in specific cases.” *Id.*

¹⁸¹⁰ The VTTS Memo provides specific guidance on how to differentiate between personal and business travel, and air or high speed rail from other modes of transportation. See VTTS Memo at 12.

¹⁸¹¹ The TPMS study affords the agencies the opportunity to distinguish between adults and passengers, a luxury not available in every instance. Furthermore, there may be certain instances where it is appropriate to value the VTTS of children the same as adults, e.g. rules focusing primarily on the VTTS of children.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

it is reasonable to assume the value of a child's time is not equivalent to an adult's. Nonetheless, the agencies have examined the impact of valuing children's time as equal to adults' by including them in the average vehicle occupancy rates applied in the refueling analysis and using the full VTTS for personal travel. Results indicate that the effect of this issue is minor and impacts total benefits by about one-quarter percent. The agencies will continue to consider this issue in future CAFE and CO₂ rulemakings. IPI also noted that the only portion of the TPMS publicly available was the "User's Coding Manual." Specifically, IPI argued that "the agencies' failure to make available the full data and methodology used to calculate these average occupancy figures frustrates any meaningful public review." The agencies disagree. IPI was able to submit a meaningful comment about the agencies' decision to exclude children from the occupancy-adjusted value of vehicle travel time. Furthermore, commenters knew that the agencies intended to use occupancy estimates to calculate the refueling benefit; however, the agencies did not receive any alternative estimates or methodologies from commenters. Nonetheless, the agencies have provided reference to the docket folder containing peer review documents, analysis documentation, and data for the 2011 TPMS survey.

(b) *Accounting for Improved Fuel Economy of ICE Vehicles*

The methodology for calculating the refueling benefits associated with improved fuel economy in new vehicles remains unchanged from the proposal. The CAFE model calculates the number of refueling events for each ICE vehicle in a calendar year. This is calculated as the number of miles driven by each vehicle in that calendar year divided by the product of that vehicle's on road fuel economy, tank size, and an assumption about the average share of the tank refueled at each event, as follows:

$$Refuel\ Events_{CY, Veh} = \frac{Miles_{CY, Veh}}{FE_{Veh} * Tank_{Veh} * Share_{Veh}}$$

The model then computes the cost of refueling as the product of the number of refueling events, total time of each event and value of the time spent on each event (computed as average salary), as below:

$$Cost_{CY, Veh} = Refuel\ Events_{CY, Veh} * (Event\ Time_{Veh}) * Time\ Value$$

The event time of a vehicle is calculated by summing a fixed and variable component. The fixed component is the number of minutes it is assumed each event takes, independent of any assumptions about tank size or share refueled at each event (the time it takes to get to and from the pump). The variable component is the ratio of the average number of gallons refueled for each event (the product of the tank size and share refueled) and the rate at which gallons flow from the pump. This is shown below:

$$Event\ Time_{Veh} = Fixed_{Veh} + \frac{Tank_{Veh} * Share_{Veh}}{Rate}$$

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

In order to calculate the refueling time cost, as described above, the CAFE model takes the following inputs: the value of time, the fixed time component of each refueling event, share of the tank refueled at each event, rate of flow of fuel from the pump, and vehicle tank size. The first of these is taken from DOT guidance on travel time savings. The fixed time component, share refueled, and rate of flow are calculated from survey data gathered as part of our 2010-2011 National Automotive Sampling System's Tire Pressure Monitoring System (TPMS) study.¹⁸¹² Finally, the vehicle fuel tank sizes are taken from manufacturer specs for the reference fleet and historical averages are calculated from popular models for the existing vehicle fleet, as described, below, in section [V.I.D.1.b\(9\)\(c\)9](#) on including the legacy fleet.

The agencies estimated the amount of saved refueling time using survey data gathered as part of the aforementioned TPMS study. In this nationwide study, researchers gathered information on the total amount of time spent pumping and paying for fuel. From a separate sample (also part of the TPMS study), researchers conducted interviews at the pump to gauge the distances that drivers travel in transit to and from fueling stations, how long that transit takes, and how many gallons of fuel are purchased.

The agencies focused on the interview-based responses in which respondents indicated the primary reason for the refueling trip was due to a low reading on the gas gauge. Such drivers experience a cost due to added mileage driven to detour to a filling station, as well as added time to refuel and complete the transaction at the filling station. The agencies believe that drivers who refuel on a regular schedule or incidental to stops they make primarily for other reasons (e.g., using restrooms or buying snacks) do not experience the cost associated with detouring in order to locate a station or paying for the transaction, because the frequency of refueling for these reasons is unlikely to be affected by fuel economy improvements. This restriction was imposed to exclude distortionary effects of those who refuel on a fixed (e.g., weekly) schedule and may be unlikely to alter refueling patterns as a result of increased driving range. The relevant TPMS survey data on average refueling trip characteristics are presented below in [Table II-87](#)~~Table VI-165~~.

Table II-~~87~~160 - Average Refueling Trip Characteristics for Passenger Cars and Light Trucks

	Gallons of Fuel Purchased	Round-Trip Distance to/from Fueling Station (miles)	Round-Trip Time to/from Fueling Station (minutes)	Time to Fill and Pay (minutes)	Total Time (minutes)
Passenger Cars	10	0.97	2.28	4.1	6.38

¹⁸¹² Docket for Peer Review of NHTSA/NASS Tire Pressure Monitoring System, *available at* <https://www.regulations.gov/docket?D=NHTSA-2012-0001>

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

	Gallons of Fuel Purchased	Round-Trip Distance to/from Fueling Station (miles)	Round-Trip Time to/from Fueling Station (minutes)	Time to Fill and Pay (minutes)	Total Time (minutes)
Light Trucks	13	1.08	2.53	4.3	6.83

The agencies assume that all of the round-trip time necessary to travel to and from the fueling station is a part of the fixed time component of each refueling event. However, some portion of the time to fill and pay is also a part of the fixed time component. Given the information in [Table II-87Table VI-165](#), the agencies assume that each refueling event has a fixed time component of 3.5 minutes. E.g., (for passenger cars) the sum of 2.28 minutes round trip time to/from fueling station and roughly 1.2 minutes to select and pay for fuel, remove/recap fuel tank, remove/replace fuel nozzle, etc. The time to fill the fuel tank is the variable time component; e.g., about 2.9 minutes for passenger cars ($2.28 + 1.2 + 2.9 = 6.38$ total minutes). However, the CAFE model uses a different methodology to determine the variable time component, which is explained below.

Cars have average tank sizes of about 15 gallons, SUVs/vans of about 18 gallons, and pickups of about 27 gallons (see [Table II-88Table VI-166](#) through [Table II-90Table VI-168](#) in section [VI.D.1.b\)\(9\)\(c\)9](#) on including the legacy fleet). It is a reasonable assumption that the average passenger car has a tank of 15 gallons and the average light truck has a tank of 20 gallons (there are more SUVs/vans than pickups in the light truck fleet). From these assumptions, it is calculated that the average refueling event fills approximately 65 percent of the fuel tank for both passenger cars and light trucks. This value is used as an input in the CAFE model for all three body styles (cars, SUVs/vans, and pickups).

Finally, the rate of the pump flow can be calculated either as the total gallons pumped over the assumed variable time component (approximately 3 minutes) or as the difference in the average number of gallons filled between light trucks and passenger cars over the difference in the time to fill and pay between the two classes. The first methodology implies a rate between 3 and 4 gallons per minute. Although the second methodology implies a rate of 15 gallons per minute, there is a legal restriction on the flow of gasoline from pumps of 10 gallons per minute.¹⁸¹³ Thus, the agencies assume the rate of gasoline pumps range between 4 and 10 gallons per minute, and use 7.5 gallons per minute—a value slightly above the midpoint of that range—as the average flow rate in the CAFE model.

The calculations described above are repeated for each future calendar year that light-duty vehicles of each model year affected by the CAFE standards considered in this rule would

¹⁸¹³ 40 CFR 80.22 (j), Regulation of Fuels and Fuel Additives - subpart B. Controls and Prohibitions, *available at* <https://www.law.cornell.edu/cfr/text/40/80.22>.

remain in service for each regulatory alternative. The resulting cumulative lifetime valuations of time savings account for both the reduction over time in the number of vehicles of a given model year that remain in service and the reduction in the number of miles (VMT) driven by those that stay in service. After calculating the absolute value for each regulatory alternative using the methodology and inputs described above, the model calculates the incremental value relative to the baseline as the refueling cost or benefit for that regulatory alternative. More efficient vehicles have to be refueled less often and refueling costs per vehicle decline. In previous rules this was sufficient to account for the majority of any changes in cost of refueling under different CAFE standards as the modelling permitted, since the volumes of new vehicles and existing vehicles on the road was assumed to be constant under all possible standards. However, when sales and scrappage models are included the distribution of new and vehicles varies and a different number of miles will be driven by new and used vehicles in each regulatory alternative.

IPI commented that it was inappropriate for the agencies to exclude benefits from reducing the frequency of refueling events where the primary reason for stopping at a fuel station was not to refuel a vehicle. IPI argued that fuel efficiency impacts from relaxed standards would affect all drivers regardless of their rationale for refueling, by requiring either more frequent or marginally longer refueling events.¹⁸¹⁴ The agencies note that the language in the NPRM suggested that the agencies eliminated 40 percent of the potential benefit from fewer refueling stops—where 40% represents the fraction of refueling stops that were routinely scheduled or otherwise not made in response to a low fuel reading—and this appears to have been the origin of IPI's concern.¹⁸¹⁵ In fact, the agencies did *not* apply a 40 percent discount factor to the refueling benefits; instead, the total number of additional refueling events that would result from alternative CAFE levels was calculated, and these were valued based on an assumption that their characteristics (e.g. vehicle occupancy) would match those of drivers who refueled due to a low fuel reading.

To the extent that lower fuel economy affects those who refuel on a routine schedule or incidental to stops made primarily for other reasons, the per-event cost would actually be limited to the extra time spent pumping a slightly larger volume of fuel. However, the agencies note that by assuming that all extra fuel consumed under lower CAFE standards results in added refueling trips, the agencies are adopting a conservative assumption, in the sense that it maximizes the disbenefits of alternatives to the current standards.

IPI also expressed concern that the agencies may have excluded the fuel costs and added emissions from additional miles driven in the course of the more frequent refueling events that would be required with more lenient CAFE standards, and correspondingly lower on-road fuel economy.¹⁸¹⁶ In the NPRM, the agencies asserted that these added costs are reflected in their overall estimates of fuel cost savings, while any increase in emissions is also reflected in the

¹⁸¹⁴ IPI, Appendix, NHTSA-2018-0067-12213, at 54-55.

¹⁸¹⁵ See 83 FR 43088 (Aug. 24, 2018).

¹⁸¹⁶ IPI, Appendix, NHTSA-2018-0067-12213, at 55.

reported changes in total emissions. However, IPI noted that the agencies did not clearly explain how these cost savings and emissions reductions are actually accounted for in their methodology.

The agencies' methodology fully accounts for both of these impacts through its calculation of changes in the use of new cars and light trucks due to the fuel economy rebound effect, which captures the impact on their aggregate use (VMT) that results from changes in the fuel cost of driving each mile. Studies that estimate the rebound effect analyze the relationship between VMT per time period and fuel economy or per-mile fuel costs, using data for individual vehicles, fleet-wide average values, or aggregate estimates for an entire fleet. Regardless of the level of aggregation they employ, their measures of vehicle use invariably include travel for all purposes, including any extra miles driven in the course of refueling.

Thus, the estimates of the rebound effect—the response of vehicle use to changes in fuel economy or per-mile fuel costs—inevitably capture any change in the number of miles driven for the purpose of refueling that occurs in response to higher or lower fuel economy. This change reflects the net effect of more or less frequent refueling trips required by their baseline or “pre-rebound” level of use, and any change in the number of refueling trips associated with increased or reduced driving in response to the rebound effect.

As a consequence, the agencies' estimates of changes in aggregate fuel consumption and fuel costs incorporate—that is, are net of—the volume and cost of fuel consumed by changes in vehicle use that result from the rebound effect, *including* any change in driving associated with more or less frequent refueling. Similarly, the agencies' estimates of changes in emissions resulting from vehicle storage and use (referred to as “tailpipe” or “downstream” emissions) are derived by applying per-mile emission factors to changes in aggregate vehicle travel, so they necessarily incorporate changes in vehicle use for all purposes, including more or less frequent refueling.

Furthermore, as the agencies demonstrated in the proposal with a practical example, the benefit associated with fewer miles spent refueling is *less than 23¢* per year for new vehicles. The cumulative impact of this benefit amounts to less than one tenth of percent of the costs of the rule.¹⁸¹⁷

Because all of the alternative standards evaluated in this rulemaking would permit lower fuel economy levels than under the baseline standard, per-mile driving costs would be higher and total vehicle use would decline in response. Although some (perhaps most) new vehicles would require more frequent refueling, the agencies' estimates of the change in aggregate use of new vehicles reflects (i.e., is net of) any increase in driving associated with more frequent refueling stops. As a result, the agencies' estimates of changes in total fuel consumption, aggregate fuel costs, and emissions resulting from the lower fuel economy levels that relaxing CAFE standards would permit reflect the *net* reduction in use of new cars and light trucks due to the fuel economy

¹⁸¹⁷ See 83 FR at 43088. Also, note that the 23 cents estimate was derived for a less stringent alternative than today's standards and included taxes which would have been removed had the agencies calculated this number separately.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

rebound effect, after considering any additional miles that would be driven in the course of more frequent refueling stops.

(c) *Including the Legacy Fleet*

Under more stringent regulatory alternatives, more miles will be driven by older and less efficient vehicles, and the effect is to reduce or eliminate any refueling benefit from increasing the fuel efficiency of new vehicles. Failing to include the existing fleet makes the costs of refueling artificially lower under more stringent standards because new vehicle sales are lower and not only because new vehicles are more efficient. This update to the calculation of the absolute refueling costs corrects this oversight present in the NPRM cost-benefit analysis by calculating fleet-wide absolute refueling costs before considering the incremental change relative to the baseline.

For other portions of the CAFE model, the agencies track the legacy vehicles by body style and vintage, using average measures for fuel economy, horsepower and curb weight. To estimate refueling costs for these vehicles, measures of average fuel tank sizes by body style and vintage are needed. The agencies are unaware of any data that directly estimates this value, but an estimate can be derived from publicly available data on fuel tank sizes of 17 high-volume nameplates with long histories. The tank sizes are averaged by body style, and these historical values are used as estimates of the average by body style and vintage. The vehicles included, their fuel tank sizes, and the averages are reported in [Table II-88Table VI-166](#) through [Table II-90Table VI-168](#) for cars, vans/SUVs, and pickups, respectively. The averages are used to represent the fuel tank sizes by vintage and vehicle body style. The agencies used the fuel tank sizes from [Table II-88Table VI-166](#) to [Table II-89Table VI-167](#) to determine the number of refueling events and time spent refueling to compute refueling costs using the methodology described previously in Section [VI.D.1.b\)\(9\)\(b\)9](#).

(d) Including Electric Vehicle Recharging

In addition to adding the refueling costs associated with the “legacy fleet,” this update adds the cost to recharge electric vehicles to the total refueling costs. Excluding the time spent recharging ignores a real cost borne by owners of electric vehicles, one which was noted by multiple commenters. For example, Ariel Corp. and VNG.co LLC commented that, “EVs require significant changes in consumer fueling behavior given the need to park at recharging points for long periods of time.”¹⁸¹⁸

In order to do so, it is important to first understand how many electric vehicle charging events will require the driver to wait and for how long. The answer to this question depends on the range of the electric vehicle and the length of the trip.¹⁸¹⁹ For trips shorter than the range, the driver can recharge the vehicle at times that will not require them to be actively waiting and thus there is no recharging cost. Only for trips where the vehicle is driven more miles than the range will the driver have to stop at mid-trip, a time that is assumed to be inconvenient, to recharge the vehicle at least enough to reach the intended destination.

The agencies use trip data from the National Household Transportation Survey (NHTS) to estimate the frequency and expected length of trips that exceed the range of the electric vehicle technologies in the simulation (200 and 300 mile ranges).

¹⁸¹⁸ Ariel Corp. and VNG.co LLC, Comment, NHTSA-2018-0067-7573, at 13.

¹⁸¹⁹ While the range of EVs is dependent on a number of factors, such as that grade, acceleration, and weather, the agencies take a conservative approach and assume a best-case scenario.

The NHTS data is collected from a representative random sample of U.S. households. The survey collects data on individual trips by mode of transportation. A trip is defined by the starting and ending point for any personal travel, so that vehicle trips will capture any time a car is driven. The survey includes identification numbers for households, individuals, and vehicles, and mode of transportation (including the body style of the vehicle for vehicle trips), and the date of the trip. Although some trips made in the same day may allow for convenient charging in between trips, the agencies assume that travel in the same day exceeding the range will involve the driver waiting for the vehicle to charge. Thus, the total number of miles driven by the same vehicle in a single day is summed, and it is assumed that charging stations are not conveniently available to the driver in between.

Some of the trips in the NHTS have missing information about the duration or length of the trip; these trips are excluded from the dataset. The agencies subset the dataset into three body styles—cars, vans/SUVs, and pickups—consistent groupings with how the VMT schedules and scrappage rates are estimated. The agencies exclude data on taxis and rental cars as the body style of the vehicle for these trips is not specified (they make up only 0.3 percent of the dataset, so their exclusion is unlikely to alter the estimate). [Table II-91Table VI-169](#), below, shows the resulting quantiles of the distribution of daily travel for all vehicles considered in the final dataset. This will include multiple days of travel for the same vehicle if more than one day of trip data is recorded in the NHTS.

Table II-91164 - Distribution of Per-Vehicle Daily Miles by Vehicle Type

Percentile	No. Obs.	0th	25th	50th	75th	100th
Car	113,256	0	8	18	38	1,256
SUVs/Vans	79,260	0	8	18	38	1,425
Pickups	31,733	0	9	20	42	1,343
Rentals	723	0	13	32	91	910
Taxis	1,673	0	3	7	15	422

The data in [Table II-91Table VI-169](#) shows that excluding taxis and rentals may be the best choice even if their body styles were known. For taxi trips, only the number of trips an individual driver makes in a day is known. The number of trips that the taxi cab itself makes in a day is unknown. As can be seen, the distribution of “daily” travel is to the left for taxis because not all trips for those vehicles are reported. Thus, including these vehicles would incorrectly skew the daily travel rates downwards.

The distribution of trip lengths for rental cars, on the other hand, is generally to the right of trips taken privately-owned vehicles. This is likely because individuals are travelling longer distances when they are on vacation or otherwise out-of-town. It seems likely that individuals renting cars for longer trips will not choose electric vehicles for such temporary travel. Thus,

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

including these trips in the dataset would likely overestimate the number of mid-trip charging events necessary for ordinary travel in a way that will not match what actually occurs.

From the final body style datasets, the agencies are able to calculate two measures that allow for the construction of the value of recharging time. First, the expected distance between trips that exceed the range of 200-mile and 300-mile BEVs (BEV200 and BEV300, respectively) is calculated. This is calculated as the quotient of the sum of total miles driven by each individual body style and the total number of trips exceeding the range, as shown below:

$$Charge\ Frequency_{Style,Range} = \frac{\sum_{Trip \in Style} Trip\ Length}{\sum_{Trip \in Style} [Trip\ Length > Range]}^{1820}$$

This calculates the expected frequency of enroute recharging events, or the amount of miles traveled per inconvenient recharging event. This is used later used to calculate the total expected time to recharge a vehicle.

The second measure needed to calculate the total expected recharging time is the expected share of miles driven that will be charged in the middle of a trip (causing the driver to wait and lose the value of time). In order to calculate this measure the difference of the trip length and range is summed, conditional on the trip length exceeding the range for each body style. This figure is then divided by the sum of the length of all trips for that body style. See the equation below:

$$Share\ Charged_{Style,Range} = \frac{\sum_{Trip \in Style} ([Trip\ Length > Range] * (Trip\ Length - Range))}{\sum_{Trip \in Style} Trip\ Length}$$

The calculated frequency of inconvenient charging events and share of miles driven that require the driver to wait for BEV's with 200 and 300-mile ranges are presented in [Table II-92](#)~~Table VI-170~~, below. As the table shows, cars are expected to require less frequent inconvenient charges and a smaller share of miles driven will require the driver to charge the vehicle in the middle of a trip. Pickups and vans/SUVs have fairly similar measures, with vans and SUVs requiring slightly more inconvenient charging than pickups.

Table II-~~92~~⁶⁵ - Electric Vehicle Recharging Thresholds by Body Style and Range

Body Style	Cars	Vans/SUVs	Pickups
Miles until mid-trip charging event, BEV200	2,000z	1,500	1,600

¹⁸²⁰ The denominator counts the number of incontinent recharging events by body style. It is not a measurement of VMT.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Body Style	Cars	Vans/SUVs	Pickups
Miles until mid-trip charging event, BEV300	5,200	3,500	3,800
Share of miles charged mid-trip, BEV200	6%	9%	8%
Share of miles charged mid-trip, BEV300	3%	4%	4%

The measures presented in [Table II-92Table VI-170](#), above, can be used to calculate the expected time drivers of electric vehicles of a given body style and range will spend recharging at a time that will require them to wait. First the agencies calculate the expected number of refueling events for a vehicle of a given style and range in a given calendar year. This is shown below as the expected miles driven by a vehicle in a given calendar year divided by the charge frequency of a vehicle of that style and range (from [Table II-92Table VI-170](#)).

$$Recharge\ Events_{CY, Veh \in (Style \cup Range)} = \frac{Miles_{CY, Veh}}{Charge\ Frequency_{Style, Range}}^{1821}$$

Next the agencies calculate the number of miles charged for a vehicle of a given style and range in a specific calendar year. This is the product of the number of miles driven by the vehicle and the share of miles driven that require an inconvenient charge for a vehicle of that style and range (from [Table II-92Table VI-170](#)), as presented below:

$$Miles\ Charged_{CY, Veh \in (Style \cup Range)} = Miles_{CY, Veh} * Share\ Charged_{Style, Range}$$

Then, the expected time that a driver of an electric vehicle of a given style and range will spend waiting for the vehicle to charge is calculated. This is the product of the fixed amount of time it takes to get to the charging station and the number of recharging events plus the quotient of the expected miles that will require inconvenient charging over an input assumption of the rate of which a vehicle of that style and range can be charged in a given calendar year (expressed in units of miles charged per hour). The fixed amount of time it takes to get to a charging station is set equal to the average time it takes for an ICE vehicle to get to a gas station for a refueling event, as discussed above.¹⁸²² This is shown below:

$$Charge\ Time_{CY, Veh \in (Style \cup Range)} = (Fixed_{Veh} * Recharge\ Events_{CY, Veh}) + \frac{Miles\ Charged_{CY, Veh}}{Charge\ Rate_{CY, Veh}}$$

¹⁸²¹ Note that $\sum_{Trip \in Style} Trip\ Length$ and $Miles_{CY, Veh}$ are different values. $Miles_{CY, Veh}$ is the estimated amount of VMT predicted by VMT while $\sum_{Trip \in Style} Trip\ Length$ is the sum of trips observed by the NHTS study.

¹⁸²² The agencies note that this is a conservative estimate. Gas stations vastly outnumber publicly available recharging stations and are often in more convenient locations.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The expected time that a driver will wait for their vehicle to charge can then be multiplied by the value of time estimate, as is done with gasoline, diesel, and E85 vehicles (see section [VI.D.1.b\)\(9\)\(b\)4](#) describing the current accounting for refueling time costs above).

It is worth a final note to talk about how plug-in hybrids are treated in the modelling (which remains unchanged from the NPRM). Presumably, plug-in hybrids that are taken on a trip that exceeds their electric range will be driven on gasoline and the driver will recharge the battery at a time that is convenient. For this reason, the electric portion of travel should be excluded from the refueling time calculation. The gasoline portion of travel is treated the same as other gasoline vehicles so that when the tank reaches some threshold, the vehicles is assumed to be refueled with the same fixed event time and the same rate of refueling flow.

The NPRM calculation of refueling benefits did not account for the impacts of fleet turnover—specifically the impact on “legacy” fleet vehicles and new electric vehicles. However, when the quantities of vehicles on the road varies between scenarios it becomes important to calculate the refueling costs for all vehicles since fuel economy and tank sizes (and therefore range before refueling) vary with vintage. This updated analysis adds these elements to the calculation of the refueling time and costs and is thus a more accurate estimation of the refueling benefit.

(10) *Energy security*

By amending existing standards, the final rule is expected to increase domestic consumption of gasoline by a relatively minimal amount relative to the baseline standards finalized in 2012, producing a correspondingly small increase in the Nation’s demand for crude petroleum, a commodity that is traded actively in a worldwide market. Specifically, the agencies project that this rule will increase gasoline consumption by cars and light trucks produced during model years 1978 through 2029 by 3.1 percent.¹⁸²³ Although the U.S. accounts for a sufficient (albeit diminishing) share of global oil consumption that the resulting increase in global petroleum demand will exert some upward pressure on worldwide prices, the rule is projected to increase global petroleum demand by less than one half of one percent from 2017 through 2050, so its effects on global prices is likely to be minimal.

U.S. consumption and imports of petroleum products has three potential effects on the domestic economy that are often referred to collectively as “energy security externalities,” and increases in their magnitude are sometimes cited as possible social costs of increased U.S. demand for petroleum. First, any increase in global petroleum prices that results from higher U.S. gasoline demand will cause a transfer of revenue to oil producers worldwide from consumers of petroleum, because consumers throughout the world are ultimately subject to the higher global price that results. Although this transfer is simply a shift of resources that produces no change in global economic welfare, the financial drain it produces on the U.S.

¹⁸²³ This includes fuel consumed by cars and light trucks produced during model years 1978-2017 that are on the road today during their remaining lifetimes, as well as fuel consumed by cars and light trucks projected to be manufactured during model years 2018-2029 over their entire lifetimes.

economy is sometimes cited as an external cost of increased U.S. petroleum consumption, because consumers of petroleum products are unlikely to consider it.

As the U.S. approaches self-sufficiency in petroleum production (the nation is expected to become a net exporter of petroleum by 2020), this transfer is increasingly *from U.S. consumers of refined petroleum products to U.S. petroleum producers*, so it not only leaves welfare unaffected, but even ceases to be a financial burden on the U.S. economy.¹⁸²⁴ In fact, as the U.S. becomes a net petroleum exporter, any transfer from global consumers to petroleum producers would become a financial benefit to the U.S. economy. Nevertheless, uncertainty in the nation's long-term import-export balance makes it difficult to project precisely how these effects might change in response to increased consumption.

Higher U.S. petroleum consumption can also increase domestic consumers' exposure to oil price shocks and thus increase potential costs to all U.S. petroleum users (including those outside the light duty vehicle sector, whose consumption would be unaffected by today's final rule) from possible interruptions in the global supply of petroleum or rapid increases in global oil prices. Because users of petroleum products are unlikely to consider the effect of their increased purchases on these risks, their economic value is often cited as an external cost of increased U.S. consumption. Finally, some analysts argue that domestic demand for imported petroleum may also influence U.S. military spending; because the increased cost of military activities would not be reflected in the price paid at the gas pump, this is often alleged to represent a third category of external costs from increased U.S. petroleum consumption.

Each of these three costs could rise incrementally—albeit by a very limited magnitude—as a consequence of increases in U.S. petroleum consumption—likely to result from the final rule. This section describes the extent to which each cost is expected to increase as a result of this action, whether it represents a significant economic cost (or simply a transfer of resources), and how the agencies have measured each cost and incorporated it into their analysis.

(a) *U.S. Petroleum Demand and its Effect on Global Prices*

Figure II-40~~Figure VI-63~~ illustrates the effect of the increase in U.S. fuel and petroleum demand anticipated to result from reducing CAFE and CO₂ standards on global demand for petroleum and its market price. The marginal increase in domestic demand can be represented as an outward shift in the U.S. demand curve for petroleum from its position at $D_{US,0}$ with the baseline standards for future model years in effect, to $D_{US,1}$ with the final rule standards replacing them. Because global demand is simply the sum of what each nation would purchase at different

¹⁸²⁴ The United States became a net exporter of oil on a weekly basis several times in late 2019, and EIA's AEO 2019 projects that will do so on a sustained, long-term basis by 2020; see EIA, AEO 2019 Reference Case, Table 21 <https://www.eia.gov/dnav/pet/hist/LeafHandler.ashx?n=p&s=wtntus2&f=4>

prices, the outward shift in U.S. demand causes an identical shift in the global demand schedule, as the figure shows.¹⁸²⁵

Figure II-4074 - Effect of U.S. Petroleum Demand on Global Prices and Purchases

The global supply curve for petroleum slopes upward, reflecting the fact that it is progressively costlier for oil-producing nations to explore for, extract, and deliver additional supplies of oil to the world market.¹⁸²⁶ Thus the upward shifts in the U.S. and world demand schedules cause an increase in the global price for oil, from P_0 to P_1 in the figure. U.S. purchases of petroleum increase from $Q_{US,0}$ to $Q_{US,1}$, but the resulting increase in global consumption from $Q_{G,0}$ to $Q_{G,1}$ will be slightly smaller than the increase in U.S. demand and purchases, because the amount of petroleum other nations purchase will decline slightly in response to its higher price. Spending on petroleum by U.S. buyers who purchase the additional oil will increase by the area $Q_{US,0}acQ_{US,1}$, the product of its new, higher price P_1 and the increase in U.S. consumption, $Q_{US,1}$

¹⁸²⁵ The figure exaggerates the U.S. share of total global consumption, which currently stands at 20 percent, for purposes of illustration.

¹⁸²⁶ The figure depicts the relationship between the global supply of petroleum and its worldwide price during a single time period. The global supply curve for petroleum has been shifting outward over time in response to increased investment in exploration, the ability of refineries to utilize feedstocks other than conventional petroleum, and technological innovations in petroleum extraction. The combination of these developments may also have reduced its upward slope, meaning that global supply now increases by more in response to increases in the world price than it once did.

– $Q_{US,0}$, while spending by U.S. consumers whose purchases remain unchanged will increase by the product of their previous purchases $Q_{US,0}$ and the price increase $P_1 - P_0$, or the area P_1abP_0 .

CARB asserted in their comments, that the NPRM analysis was biased against the baseline standards because the fuel prices in the NPRM were based on a unique run of DOE's NEMS model that included the baseline.¹⁸²⁷ They argued that the proposal would have reduced fleet average fuel economy, leading to increased demand and subsequently higher fuel prices faced by consumers. As a result, the additional fuel costs associated with the proposal (relative to the baseline) should have been even higher than estimated because the fuel price faced by drivers in that scenario would have been higher than in the baseline. However, while the difference between the baseline and preferred alternative could create differences in fleet fuel economy in a manner that could influence prices at the pump, those differences are likely to be small. In response to CARB's comments, the agencies conducted additional runs with NEMS to compare the fuel price under the baseline standards and the fuel price under the proposed standards. Through 2050, the fuel price difference between the alternatives was never higher than two percent. The standards being finalized in this rule are considerably closer to the baseline than were those in the proposal.

SAFE commented that the United States is a "price-taker" in the global market and "must accept the prevailing global oil price since it lacks sufficient market power to influence decisively this price."¹⁸²⁸ This comment, however, is directly at odds with both the economics of the world oil market shown in [Figure II-40](#)~~Figure VI-63~~ above and other comments asserting that the increase in U.S. gasoline demand resulting from this rule will increase U.S. and global petroleum demand, thus increasing world oil prices. In response to the comment from SAFE, the agencies utilized a forecast of fuel prices in today's analysis that considers the effect of the revised standards on global petroleum demand and prices. This assumption slightly increases the cost of forgone fuel savings in the preferred alternative, compared to their value under the assumption that U.S. demand cannot change global prices and the nation acts as a price-taker.

In [Figure II-40](#)~~Figure VI-63~~, the increase in the price of oil from P_0 to P_1 will mean that global consumers who previously purchased the quantity of oil $Q_{G,0}$ at its lower price will now pay more for that same amount. Specifically, previous purchasers will pay the additional area P_1deP_0 , whose value is the increase in price $P_1 - P_0$ multiplied by the volume they originally bought, $Q_{G,0}$. Of this increase in revenue to oil producers, the rectangular area P_1abP_0 —which as indicated above is the product of the increase in price $P_1 - P_0$ and previous U.S. purchases $Q_{US,0}$, and thus measures the increase in spending by previous U.S. consumers—is simply transferred from U.S. consumers to global oil suppliers.¹⁸²⁹ The remaining fraction of increased payments to producers, the rectangular area $adeb$, whose value is the product of the price increase $P_1 - P_0$ and previous purchases by other nations, which were $Q_{G,0} - Q_{US,0}$, is a transfer from consumers outside the U.S. to global oil producers.

¹⁸²⁷ NHTSA-2018-0067-11873.

¹⁸²⁸ NHTSA-2018-0067-11981.

¹⁸²⁹ Note that global oil suppliers include domestic as well as US-owned foreign suppliers.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The total increase in global spending—including the additional spending by U.S. consumers as well as by those in other nations—on the amount of oil they previously purchased is simply a transfer of revenue from consumers of petroleum products to oil producers. This transfer can be described as a “pecuniary” externality, since it describes the effect of the price increase on wealth allocation, but is considered separately from any effects on quantity produced and consumed. Some of the increase in payments by U.S. consumers for the petroleum products they originally consumed may be made to foreign-owned oil producers, and thus represents a financial drain on the U.S. economy, while the remainder is received by domestic producers and thus remains within the U.S. economy.¹⁸³⁰

To an increasing extent, however, the additional payments by U.S. consumers that result from upward pressure on the world oil price are a transfer *entirely within* the Nation’s economy, because a growing fraction of domestic petroleum consumption is supplied by U.S. producers. The U.S. is projected to become a net *exporter* of petroleum in 2020—and in fact became a net exporter in September 2019—and as the Nation moves toward that status, an increasing share of any higher costs paid by U.S. consumers of petroleum products becomes a gain to U.S. oil producers.¹⁸³¹ When the U.S. becomes self-sufficient in petroleum supply—which is now anticipated to occur in the year this final rule publishes—the *entire* value of increased payments by U.S. petroleum users that results from relaxing CAFE and CO₂ standards will have the same effect as if it were simply a transfer within the U.S. economy. As a consequence, the financial burden that transfers from U.S. consumers to foreign producers places on the U.S. economy will disappear.

Over almost the entire time period spanned by the analysis of this final rule, any increase in domestic spending for petroleum caused by the effect of higher U.S. fuel consumption and petroleum use on world oil prices is expected on balance to be a transfer within the U.S. economy and thus produce no drain on domestic economic resources. For this reason—and because in any case such transfers do not create real economic costs or benefits—increased U.S. spending on petroleum products that results from increased U.S. fuel demand and any resulting upward pressure on petroleum prices stemming from this action is not included among the economic costs accounted for in this final rule.

(b) *Macroeconomic Costs of U.S. Petroleum Consumption*

In addition to influencing global demand and prices, U.S. petroleum consumption imposes further costs that are unlikely to be reflected in the market price for petroleum, or in the

¹⁸³⁰ Neither transfer, however, has an effect on domestic or global economic welfare.

¹⁸³¹ The U.S. Energy Information Administration EIA estimates that the United States exported more total crude oil and petroleum products in September and October of 2019, and expects the United States to continue to be a net exporter. See *Short Term Energy Outlook November 2019*, available at <https://www.eia.gov/outlooks/steo/archives/nov19.pdf>.

prices paid by consumers of refined products such as gasoline.¹⁸³² Petroleum consumption imposes external economic costs by exposing the U.S. economy to increased risks of rapid increases in prices triggered by global events that may also disrupt the supply of imported oil, and U.S. consumers of petroleum products are unlikely to take such costs into account when making their decisions about how much to consume.

Sudden interruptions in oil supply and rapid increases in its price can impose significant economic costs, because they raise the costs of producing all commodities whose manufacturing and distribution consumes petroleum, thus temporarily reducing the level of output that the U.S. economy can produce using its available supplies of labor and capital. The magnitude of any reduction in economic output depends on the extent and duration of the increases in prices for petroleum products that result from a disruption in global oil supplies, as well as on whether and how rapidly prices return to their pre-disruption levels—which in turn depends largely on the rest of the world's capability to respond to interruptions by increasing production elsewhere. Even if prices for oil return completely to their original levels, however, economic output will be at least temporarily reduced from the level that would have been possible with uninterrupted oil supplies and stable prices, so the U.S. economy will bear some transient losses it cannot subsequently recover.

Supply disruptions and price increases caused by global political events tend to occur suddenly and unexpectedly, so they can also force businesses and households to adjust their use of petroleum products more rapidly than if the same price increase occurred gradually. Rapid substitutions between energy derived from oil and other forms of energy, as well as between energy and other inputs, and other changes such as adjusting production levels and downstream prices, can be costly for businesses to make. As with businesses, sudden changes in energy prices and use are also difficult for households to adapt to quickly or smoothly, and doing so may impose at least temporary costs or losses in utility for the various adjustments they make.

Interruptions in oil supplies and sudden increases in petroleum prices are both uncertain prospects, and the costs of the disruptions they can cause must be weighted or adjusted by the probability that they will occur, as well as for their uncertain duration. The agencies estimate this expected cost of such disruptions by combining the probabilities that price increases of different magnitudes and durations will occur during the future period spanned by their analysis with the costs of reduced U.S. economic output and abrupt adjustments to sharply higher petroleum prices. Any *change* in the probabilistic “expected value” of such costs that can be traced to higher U.S. fuel consumption and petroleum demand stemming from this final rule to establish less demanding fuel economy standards is considered to be an external cost of the adopting it.

¹⁸³² See, e.g., Bohi, D. R. & W. David Montgomery (1982), *Oil Prices, Energy Security, and Import Policy* Washington, D.C. - Resources for the Future, Johns Hopkins University Press; Bohi, D. R., & M. A. Toman (1993), “Energy and Security - Externalities and Policies,” *Energy Policy* 21:1093-1109; and Toman, M. A. (1993). “The Economics of Energy Security - Theory, Evidence, Policy,” in A. V. Kneese and J. L. Sweeney, eds. (1993), *Handbook of Natural Resource and Energy Economics, Vol. III*, Amsterdam - North-Holland, pp. 1167-1218.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

A variety of mechanisms exist to “insure” against higher petroleum prices and reduce their costs for adjusting to sudden price increases, including making purchases or sales in oil futures markets, adopting energy conservation measures, diversifying the fuel economy levels within the set of vehicles owned by the household, locating where public transit provides a viable alternative to driving, and installing technologies that permit rapid fuel switching. Growing reliance on such measures, coupled with continued improvements in energy efficiency throughout the economy, has certainly reduced the vulnerability of the U.S. economy to the costs of oil shocks in recent decades.

Thus, there is now considerable debate about the magnitude and continued relevance of potential economic damages from sudden increases in petroleum prices. The petroleum intensity of the U.S. economy has declined considerably and global oil prices are dramatically lower than when analysts first identified and quantified the risks they create to the U.S. economy. Further, not only has the Nation dramatically increased its own petroleum supply, but other new global supplies have emerged as well, both of which reduce the potential impact of disruptions that occur in unstable or vulnerable regions where oil is produced.

As a consequence, the potential macroeconomic costs of sudden increases in oil prices are now likely to be considerably smaller than when they were original identified and estimated. Research by the National Research Council (2009) argued that non-environmental externalities associated with dependence on foreign oil are small, and perhaps trivial.¹⁸³³ Research by Nordhaus and by Blanchard and Gali have also questioned how harmful to the economy oil price shocks have been, noting that the U.S. economy actually expanded immediately after the most recent oil price shocks, and that there was little evidence of higher energy prices being passed through to higher wages or prices.¹⁸³⁴

¹⁸³³ National Research Council, *Hidden Costs of Energy - Unpriced Consequences of Energy Production and Use*, National Academy of Sciences, Washington, D.C. (2009).

¹⁸³⁴ Nordhaus argues that one reason for limited vulnerability to oil price shocks is that monetary policy has become more accommodating to the price impacts, while another is that U.S. consumers and businesses may determine that such movements are temporary and abstain from passing them on as inflationary price increases in other parts of the economy. He also notes that changes in productivity in response to recent oil price increases are have been extremely modest, observing that “energy-price changes have no effect on multifactor productivity and very little effect on labor productivity.” at p. 19. Blanchard and Gali (2010) contend that improvements in monetary policy, more flexible labor markets, and the declining energy intensity of the U.S. economy (combined with an absence of concurrent shocks to the economy from other sources) lessened the impact of oil price shocks after 1980. They find that “the effects of oil price shocks have changed over time, with steadily smaller effects on prices and wages, as well as on output and employment...The message...is thus optimistic in that it suggests a transformation in U.S. institutions has inoculated the economy against the responses that we saw in the past.” at p. 414. See William Nordhaus, “Who’s Afraid of a Big Bad Oil Shock?” Available at http://aida.econ.yale.edu/~nordhaus/homepage/Big_Bad_Oil_Shock_Meeting.pdf; and Blanchard, Olivier and Jordi Gali, J., “The Macroeconomic Effects of Oil price Shocks - Why are the 2000s so Different from the 1970s?,” in Gali, Jordi and Mark Gertler, M., eds., *The International Dimensions of Monetary Policy*, University of Chicago Press, February (2010), pp. 373-421, available at <http://www.nber.org/chapters/c0517.pdf>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Since these studies were issued in 2009 and 2010, the petroleum intensity of the U.S. economy has continued to decline while domestic energy production has increased in ways and to an extent that experts failed to predict, so that the U.S. became the world's largest producer in 2018.¹⁸³⁵ The U.S. shale oil revolution has both established the potential for energy independence and placed downward pressure on prices. Lower oil prices are also a result of sustained reductions in U.S. consumption and global demand resulting from energy efficiency measures, many undertaken in response to previously high oil prices.

Reduced petroleum intensity and higher U.S. production have combined to produce a decline in U.S. petroleum imports—to approximately 20 percent of domestic consumption in 2017—which permits U.S. supply to act as a buffer against artificial or natural restrictions on global petroleum supplies due to military conflicts or natural disasters. In addition, the speed and relatively low incremental cost with which U.S. oil production has increased suggests that both the magnitude and (especially) the duration of future oil price shocks may be limited, because U.S. production offers the potential for a large and relatively swift supply response.

And while some risk of price shocks certainly still exists, even the potential for a large and swift U.S. production response may be playing a role in limiting the extent of price shocks attributable to external events. The large-scale attack on Saudi Arabia's Abqaiq processing facility—the world's largest crude oil processing and stabilization plant—on September 14, 2019 caused “the largest single-day [crude oil] price increase in the past decade,” of between \$7 and \$8 per barrel, according to EIA.¹⁸³⁶ The Abqaiq facility has the capacity to process 7 million barrels per day, or about 7 percent of global crude oil production capacity. EIA declared, however, that by September 17, only three days after the incident:

Saudi Aramco reported that Abqaiq was producing 2 million barrels per day, and they expected its entire output capacity to be fully restored by the end of September. In addition, Saudi Aramco stated that crude oil exports to customers will continue by drawing on existing inventories and offering additional crude oil production from other fields. Tanker loading estimates from third-party data sources indicate that loadings at two Saudi Arabian export facilities were restored to the pre-attack levels. Likely driven by news of the expected return of the lost production capacity, both Brent and WTI crude oil prices fell on Tuesday, September 17.¹⁸³⁷

Thus, the largest single-day oil price increase in the past decade was largely resolved within a week, and assuming very roughly that average crude oil prices were \$70/barrel in September 2019 (slightly higher than actual), an increase of \$7/barrel would represent a 10 percent increase as a result of the Abqaiq attack. Contrast this with the 1973 Arab oil embargo,

¹⁸³⁵ See U.S. Energy Information Administration EIA, *Today in Energy August 20, 2019*, available at <https://www.eia.gov/todayinenergy/detail.php?id=40973>; *Today in Energy September 12, 2018*, available at <https://www.eia.gov/todayinenergy/detail.php?id=37053>

¹⁸³⁶ <https://www.eia.gov/todayinenergy/detail.php?id=41413>

¹⁸³⁷ *Id.*

which lasted for months and raised prices 350 percent.¹⁸³⁸ Saudi Arabia could have experienced increased revenue resulting from higher prices following the Abqaiq attack, but instead moved rapidly to restore production and tap reserves to control the risk of resulting price increases. In doing so, the Saudis likely recognized that sustained, long-term price increases would reduce their ability to control global supply (and thus prices and their own revenues) by relying on their lower cost of production.¹⁸³⁹

Some commenters asserted that U.S. shale oil resources cannot serve as “swing supply” to provide stability in the face of a sudden, significant global supply disruption (Jason Bordoff, SAFE).^{1840, 1841} Despite its greater responsiveness to price changes, commenters argued that lead time to bring new shale resources to market (6-12 months) is inferior to “true spare capacity” (like Saudi Arabia’s large oil fields) because it cannot be deployed quickly enough to mitigate the economic consequences resulting from rapidly rising oil prices. Bordoff, however, also notes that shale oil projects’ lead times are still shorter—and possibly much shorter—than conventional oil resource development. So, while new U.S. oil resources may take some time to respond to supply disruptions, they are nevertheless likely to provide a stabilizing influence on supply.

This is especially true for price increases that occur more slowly. When Beccue and Huntington updated their 2005 estimates of supply disruption probabilities in 2016,¹⁸⁴² they found that the probability distribution was generally flatter—suggesting that supply disruptions of most potential magnitudes were less likely to occur under today’s market conditions than they had estimated previously in 2005. In particular, Beccue and Huntington find that supply disruptions of between two and four million barrels per day are significantly less likely than their previous estimates suggested. Although their recent study also estimated that larger supply disruptions (nine or more million barrels per day) are now slightly more likely to occur than in previous estimates, disruptions of that magnitude are extremely unlikely under either set of estimates.

Based on this review of the literature, the agencies concede that shale resources may not be able to stabilize oil markets fully to prevent a price increase associated with a large supply disruption elsewhere in the world. However, if supply disruptions are small enough, or move slowly enough, U.S. resources may be an adequate stabilizer.

The agencies reviewed further research that emphasizes the continued threat to the U.S. economy posed by the potential for sudden increases in global petroleum prices.¹⁸⁴³ For example, Ramey and Vine (2010) note “remarkable stability in the response of aggregate real variables to oil shocks once we account for the extra costs imposed on the economy in the 1970s by price controls and a complex system of entitlements that led to some rationing and shortages.”¹⁸⁴⁴ In contrast, another recent study found that while the likely effects of sudden oil price increases have become smaller over time, the declining sensitivity of petroleum demand to prices means that any future disruptions to oil supplies will have larger effects on petroleum prices, so that on balance their economic impact is likely to remain significant.¹⁸⁴⁵

Some commenters (SAFE, CARB, Fuel Freedom Foundation, IPI) expressed skepticism that the United States could become a net petroleum exporter in the future without the continuation of the baseline standards. They cautioned that the global oil market is inherently uncertain, and Bordoff cautioned that America’s shale resources may not last as long, or be as easy to develop, as they currently appear.¹⁸⁴⁶ If the U.S. does not become a net exporter of petroleum as anticipated, any wealth effects from a high price of oil would continue to accrue to foreign owners of oil reserves. In addition, several of these commenters (CARB, SAFE, Bordoff, Zozana) argued that, regardless of whether or not the U.S. becomes a net petroleum exporter, its levels of petroleum consumption make it still vulnerable to price shocks arising in the global oil market.

The agencies believe that the United States lacks the power (significantly) to control the global oil price and as a consequence remains vulnerable to the effects of oil price spikes, regardless of our own oil output. Geopolitical factors influence the global oil price—unstable regimes are often unreliable suppliers, large suppliers attempt strategically to manage supply to influence price or retain market share, and international negotiations around politically sensitive topics can influence the production behavior of firms in oil-rich nations. All of these factors, as well as wars and natural disasters, can influence the global supply and the market price for oil.

In this analysis, any increase in the expected value of potential costs from economy-wide disruptions caused by sudden price increases that results from higher U.S. fuel and petroleum demand is accounted for separately from the direct cost for increased purchases of

¹⁸⁴³ Hamilton (2012) reviewed the empirical literature on oil shocks and concluded that its findings are mixed, noting that some recent research (e.g., Rasmussen and Roitman, 2011) finds either less evidence for significant economic effects of oil price shocks or declining effects (Blanchard and Gali 2010), while other research finds evidence of their continuing economic importance. See Hamilton, J. D., “Oil Prices, Exhaustible Resources, and Economic Growth,” in *Handbook of Energy and Climate Change* available at http://econweb.ucsd.edu/~jhamilto/handbook_climate.pdf http://econweb.ucsd.edu/~jhamilto/handbook_climate.pdf.

¹⁸⁴⁶ NHTSA-2018-0067-10718.

petroleum products. Consumers of petroleum products are unlikely to consider their contributions to these costs when deciding how much energy to consume, because those costs will be distributed widely throughout the economy, falling largely on businesses and households other than those whose decisions impose them. Thus, they represent an external (or “social”) cost that users of petroleum energy such as transportation fuel are unlikely to internalize fully, and the agencies analysis includes the estimated increase in these costs among of the social costs stemming from the final rule. While increased U.S. petroleum production may impose some limits on their potential magnitude, their underlying source continues to be domestic petroleum *use* rather than imports.

Although the vulnerability of the U.S. economy to oil price shocks depends on aggregate petroleum consumption rather than on the level of oil imports, variation in U.S. oil imports may itself have some effect on the frequency, size, or duration of sudden oil price increases. The expected value of the resulting economic costs would also depend partly on the fraction of U.S. petroleum use that is supplied by imports. While total U.S. petroleum consumption is the primary determinant of potential economic costs to the Nation from rapid increases in oil prices, the estimate of these costs that have been relied upon on in past regulatory analyses—and in this analysis—is nevertheless expressed per unit (barrel) of *imported* oil. When they are converted to a per-gallon basis, they thus apply to fuel that is either imported in refined form, or refined domestically from imported crude petroleum.

[Table II-93Table VI-174](#) reports the per-barrel estimates of external costs from potential oil price shocks this analysis uses to estimate the increase in their total value likely to result from this final rule. These values differ from those used in previous analysis of CAFE and CO₂ standards. In their comments on the NPRM, SAFE pointed out recent studies that have updated the estimates of the oil security premium since the study—on which the agencies relied upon in the NPRM—had been published. They depend in part on projected future oil prices, the elasticities of consumption with respect to price, income, and U.S. GDP. Since the NPRM values were last updated by the agencies, all of these factors have evolved in directions that would reduce the magnitude of the oil security premium, so continuing to use the NPRM values would have overestimated the increase in expected costs to the U.S. economy from potential oil price shocks calculated in this analysis, perhaps significantly.¹⁸⁴⁷

Specifically, the global petroleum prices projected in EIA’s Annual Energy Outlook 2018 Reference Case range from 33-57 percent below those used to develop the estimates used in the NPRM and reported in [Table II-93Table VI-174](#). U.S. petroleum consumption and imports are now projected to be 3-8 percent and 20-27 percent lower than the forecast values used to

¹⁸⁴⁷ The costs reported in [Table II-93Table I-4](#) also depend on the probabilities or expected frequencies of supply interruptions or sudden price shocks of different sizes and durations. The most recent reassessment of the probabilities on which these estimates are based (which were originally developed in 2005) was conducted in 2016; see Beccue, Phillip C. and Hillard G. Huntington, An Updated Assessment of Oil Market Disruption Risks - Final Report EMF SR 10, Stanford University Energy Modeling Forum (February 5, 2016) available at <https://emf.stanford.edu/publications/emf-sr-10-updated-assessment-oil-market-disruption-risks>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

construct the NPRM estimates in the table. Finally, total petroleum expenditures are now projected to average 1.5-2.4 percent of U.S. GDP, in contrast to the 3.8-4.0 percent shares reflected in those values. Each of these differences suggests that the values in the NPRM overstated the current magnitude of potential costs to the U.S. economy from the risk of petroleum price shocks, and together they suggest that this overstatement may be significant. Indeed, the values used to support this final rule analysis are sourced from a recent paper by Brown.¹⁸⁴⁸ Brown updates the underlying parameters used to estimate the oil security premium and finds a range of \$0.60 - \$3.45 per barrel of imported oil, with a mean of \$1.26 per barrel. The study, which was cited by SAFE, determines that the U.S. is less much less sensitive to oil price shocks than earlier estimates imply.¹⁸⁴⁹ The values used in today's rule reflect that conclusion.

Table II-93466 – Expected Cost of Petroleum Price Shocks from Increased Fuel Imports

Year	Oil Security Premium (2018\$/barrel) ¹⁸⁵⁰	
	NPRM	Final Rule
2015	8.44	1.21
2016	8.44	1.28
2017	8.44	1.30

2048	10.75	2.53
2049	10.75	2.57
2050	10.75	2.61

Because they are expressed per barrel of petroleum that is imported (either in already-refined form as gasoline, or as crude petroleum to be refined domestically), applying these estimates requires the agencies to project of any changes in U.S. petroleum imports that are likely to result from the higher level of fuel consumption anticipated to occur as a result of this final rule. As discussed in detail in Section 6.D.3.(b) of this final rule, the agencies have elected to retain their previous assumptions that 50 percent of any increase in fuel consumption attributable to the rule will be accounted for through imports in refined form, and that 90 percent of the remaining increase would be refined domestically from imported petroleum. As a consequence, the oil security premiums shown in [Table II-93](#)~~Table VI-171~~ are considered to be

an external cost associated with 95 percent of the increase in gasoline consumption projected to result from this final rule.¹⁸⁵¹

(c) *Potential Effects of Fuel Consumption and Petroleum Imports on U.S. Military Spending*

A third potential effect of increasing U.S. demand for petroleum is an increase in U.S. military spending to secure the supply of oil imports from potentially unstable regions of the world and protect against their interruption. If an increase in fuel consumption that results from reducing CAFE and CO₂ standards lead to higher military spending to protect oil supplies, this increase in outlays would represent an additional external or social cost of the agencies' action. Such costs could also include increased costs to maintain the U.S. Strategic Petroleum Reserve (SPR), because it is intended to cushion the U.S. economy against disruptions in the supply of imported oil or sudden increases in the global price of oil.

While several commenters argued that current U.S. military expenditures are uniquely attributable to securing U.S. supplies of petroleum from unstable regions of the globe—the Middle East, in particular—should be considered as a cost of this action (CARB, SAFE, Zonana), they seemed to confuse those costs with the *marginal* impact of increased oil consumption (relative to the baseline) on U.S. military activity and its costs. However, the agencies disagree with commenters that incremental changes to domestic consumption of oil for light-duty transportation could meaningfully change the scope or scale of the U.S. Department of Defense mission in the Persian Gulf region. Instead, they side with the Fuel Freedom Foundation, which noted in its comment, “[i]ncrementally decreasing petroleum consumption does not significantly decrease the military spending to protect and ensure its flow around the world.”¹⁸⁵²

SAFE estimated a per-gallon cost of military externalities associated with U.S. dependence on petroleum products, and imported petroleum specifically.¹⁸⁵³ Their low estimate of \$0.28/gallon assumes \$81 billion per year for protection of the global petroleum supply and divides those costs by the number of gallons consumed by U.S. drivers. In contrast, a similar analysis by Crane et al. stated, “our analysis addresses the incremental cost to the defense budget of defending the production and transit of oil. It does not argue that a partial reduction of the U.S. dependence on imported oil would yield a proportional reduction in U.S. spending that is focused on this mission. The effect on military cost from such changes in petroleum use would be minimal.”¹⁸⁵⁴ The agencies thus do not believe that any incremental petroleum consumption

¹⁸⁵¹ The 95 percent figure is calculated as 50 percent plus 90 percent of the remaining 50 percent, or 50 percent plus 45 percent.

¹⁸⁵² NHTSA-2018-0067-12016.

¹⁸⁵³ NHTSA-2018-0067-11981.

¹⁸⁵⁴ Crane, K., A. Goldthau, M. Toman, T. Light, S. E. Johnson, A. Nader, A. Rabasa, & H. Dogo, *Imported Oil and U.S. National Security*, Santa Monica, CA, The RAND Corporation (2009) available at <https://www.rand.org/pubs/monographs/MG838.html>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

that may result from this final rule will influence any fraction of U.S. defense spending that can be ascribed to protecting the global oil network.

Eliminating petroleum imports (to both the U.S. and its national security allies) *entirely* might permit the Nation to scale back its military presence in oil-supplying regions of the globe to the extent that such interventions are driven by narrow concerns for oil production rather than other geopolitical considerations, but there is little evidence that U.S. military activity and spending in those regions have varied over history in response to fluctuations in the Nation's oil imports, or are likely to do so over the future period spanned by this analysis. [Figure II-41](#) [Figure VI-64](#) shows that military spending as a share of total U.S. economic activity has gradually declined over the past several decades, and that any temporary—although occasionally major—reversals of this longer-term decline have been closely associated with U.S. foreign policy initiatives or overseas wars.

Figure II-41 - Historical Variation in U.S. Military Spending (Percent of U.S. Gross Domestic Product)

Figure II-42

[Figure VI-65](#) superimposes U.S. petroleum consumption and imports on the history of military spending shown in the previous figure. Doing so shows that variation in U.S. military

Formatted: Normal, Left, Space Before: 0 pt, After: 0 pt

Formatted: Font:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

spending throughout this period has had little association with the historical pattern of domestic petroleum purchases, changes in which instead primarily reflected the major increases in global petroleum prices that occurred in 1978-79, 2008, and 2012-13. More important, [Figure II-42](#) ~~Figure VI-65~~ also shows that U.S. military spending varied almost completely independently of the nation's imports of petroleum over this period. This history suggests that U.S. military activities—even in regions of the world that have historically represented vital sources of oil imports—serve a far broader range of security and foreign policy objectives than simply protecting oil supplies. Thus, reducing the nation's consumption or imports of petroleum is unlikely by itself to lead to reductions in military spending.

SAFE further argued in its comments that the America's involvement in wars in the Persian Gulf region, starting with the first Gulf War and continuing through the Iraq War, has been a direct consequence of our dependence upon oil. In particular, they state that “[w]hile there is debate over the precise role of oil in America's wars in the greater Middle East, several retired military members of SAFE's ESLC and other defense budget experts that were consulted for this report believe the connection is clear.”¹⁸⁵⁵ However, neither today's action, nor the baseline standards, has the ability to change the historical wealth transfer that created powerful nations in the Middle East. Attributing the cost of the Iraq War, for example, to oil dependence does not directly support an assertion that a marginal reduction in oil dependence could have reduced the cost of that conflict.

¹⁸⁵⁵ NHTSA-2018-0067-11981.

Figure II-4273 - Historical Variation in U.S. Military Spending in Relation to U.S. Petroleum Consumption and Imports (Percent of U.S. Gross Domestic Product)

Further, the agencies were unable to find a record of the U.S. government attempting to calibrate U.S. military expenditures, force levels, or deployments to any measure of the Nation's petroleum use and the fraction supplied by imports, or to an assessment of the potential economic consequences of hostilities in oil-supplying regions of the world that could disrupt the global market.¹⁸⁵⁶ Instead, changes in U.S. force levels, deployments, and spending in such

¹⁸⁵⁶ Crane et al. (2009) analyzed reductions in U.S. forces and associated cost savings that could be achieved if oil security were no longer a consideration in military planning, and disagree with this assessment. After reviewing recent allocations of budget resources, they concluded that "...the United States *does* include the security of oil supplies and global transit of oil as a prominent element in its force planning" at p. 74 (emphasis added). Nevertheless, their detailed analysis of individual budget categories estimated that even eliminating the protection of foreign oil supplies *completely* as a military mission would reduce the current U.S. defense budget by approximately 12-15 percent. See Crane, K., A. Goldthau, M. Toman, T. Light, S. E. Johnson, A. Nader, A. Rabasa, & H. Dogo, *Imported Oil and U.S. National Security*, Santa Monica, CA, The RAND Corporation (2009) available at <https://www.rand.org/pubs/monographs/MG838.html>.

regions appear to have been governed by purposeful foreign policy initiatives, unforeseen political events, and emerging security threats, rather than by shifts in U.S. oil consumption or imports.¹⁸⁵⁷

The agencies thus conclude that U.S. military activity and expenditures are unlikely to be affected by even relatively large changes in consumption of petroleum-derived fuels by light duty vehicles. Certainly, the historical record offers no suggestion that U.S. military spending is likely to adjust significantly in response to the increase in domestic petroleum use that would result from reducing CAFE and CO₂ standards.

Nevertheless, it is possible that more detailed analysis of military spending might identify some relationship to historical variation in U.S. petroleum consumption or imports. A number of studies have attempted to isolate the fraction of total U.S. military spending that is attributable to protecting overseas oil supplies.¹⁸⁵⁸ These efforts have produced varying estimates of how much it might be reduced if the U.S. no longer had *any* strategic interest in protecting global oil supplies. However, none has identified an estimate of spending that is likely to vary incrementally in response to changes in U.S. petroleum consumption or imports.

Nor have any of these studies tracked changes in spending that can be attributed to protecting U.S. interests in foreign oil supplies over a prolonged period, so they have been unable to examine whether their estimates of such spending vary in response to fluctuations in domestic petroleum consumption or imports. The agencies conclude from this review of research that U.S. military commitments in the Persian Gulf and other oil-producing regions of

¹⁸⁵⁷ Crane et al. (2009) also acknowledge the difficulty of reliably allocating U.S. military spending by specific mission or objective, such as protecting foreign oil supplies. Moore et al. (1997) conclude that protecting oil supplies cannot be distinguished reliably from other strategic objectives of U.S. military activity, so that no clearly separable component of military spending to protect oil flows can be identified, and its value is likely to be near zero. Similarly, the U.S. Council on Foreign Relations (2015) takes the view that significant foreign policy missions will remain over the foreseeable future even without any imperative to secure petroleum imports. A dissenting view is that of Stern (2010), who argues that other policy concerns in the Persian Gulf derive from U.S. interests in securing oil supplies, or from other nations' reactions to U.S. policies that attempt to protect its oil supplies. See Crane, K., A. Goldthau, M. Toman, T. Light, S.E. Johnson, A. Nader, A. Rabasa, and H. *** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

the world contribute to worldwide economic and political stability, and insofar as the costs of these commitments are attributable to petroleum use, they are attributable to oil consumption throughout the world, rather than simply U.S. oil consumption or imports.

It is thus unlikely that military spending would rise in response to any increase in U.S. imports that did result from this final rule. As a consequence, the analysis of alternative CAFE and CO₂ emission standards for future model years applies no increase in government spending to support U.S. military activities as a potential cost of allowing new cars and light trucks to achieve lower fuel economy and thus increasing domestic petroleum use.

Similarly, while the ideal size of the Strategic Petroleum Reserve from the standpoint of its potential stabilizing influence on global oil prices may be related to the level of U.S. petroleum consumption or imports, its actual size has not appeared to vary in response to either of those measures. The budgetary costs for maintaining the SPR are thus similar to U.S. military spending in that, while they are not reflected in the market price for oil (and thus do not enter consumers' decisions about how much to use), they do not appear to have varied in response to changes in domestic petroleum consumption or imports.

As a consequence, the analysis does not include any potential increase in the cost to maintain a larger SPR among the external or social costs of the increase in gasoline and petroleum consumption likely to result from reducing future CAFE and CO₂ standards. This view aligns with the conclusions of most recent studies of military-related costs to protect U.S. oil imports, which generally conclude that savings in military spending are unlikely to result from incremental reductions in U.S. consumption of petroleum products on the scale of those that would result from adopting higher CAFE or CO₂ standards.

(11) *Social cost of carbon*

In the proposal, the agencies projected costs resulting from fuel consumption and emissions of CO₂ using estimates of anticipated climate-related economic damages within U.S. borders per ton of CO₂ emissions, which the agencies referred to as the domestic social cost of carbon (domestic SC-CO₂). The domestic SC-CO₂ estimates, which were originally developed by EPA for an earlier regulatory analysis, represent the monetary value of damages to the domestic economy likely to be caused by future changes in the climate that result from incremental increases in CO₂ emissions during a given year.¹⁸⁵⁹ The agencies did not consider climate-related damage costs resulting from emissions of other greenhouse gases (GHGs), such

¹⁸⁵⁹ For a description of the procedures EPA used to develop these values, see U.S. Environmental Protection Agency, *Regulatory Impact Analysis for the Proposed Emission Guidelines for Greenhouse Gas Emissions from Existing Electric Utility Generating Units; Revisions to Emission Guideline Implementing Regulations; Revisions to New Source Review Program*, EPA-452/R-18-006, August 2018 (https://www.epa.gov/sites/production/files/2018-08/documents/utilities_ria_proposed_ace_2018-08.pdf), Section 4.3, at 4-2 to 4-7. The sources and potential magnitude of uncertainties surrounding the SC-CO₂ estimates are described in Chapter 7 of that same document, at 7-1 to 7-10.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

as methane or nitrous oxide, in their analysis supporting the proposal.

Climate-related damages caused by emissions of CO₂ and other GHGs include changes in agricultural productivity, adverse effects on human health, property damage from increased flood risk, and changes in costs for managing indoor environments in commercial and residential buildings (such as costs for heating and air conditioning), among other possible damages.

The agencies described the SC-CO₂ estimates used in the NPRM analysis as interim values developed under Executive Order 13783, which are to be used in regulatory analyses until revised values that incorporate recommendations from NAS can be developed.¹⁸⁶⁰ E.O. 13783 directed agencies to ensure that estimates of the social cost of greenhouse gases used in regulatory analyses are consistent with the guidance contained in OMB Circular A-4, “including with respect to the consideration of domestic versus international impacts and the consideration of appropriate discount rates.”¹⁸⁶¹

Circular A-4 states that analysis of economically significant regulations “should focus on benefits and costs that accrue to citizens and residents of the United States,” and the agencies followed this guidance by using estimates of the SC-CO₂ that included only domestic economic damages. In response to Circular A-4’s further guidance that regulatory analyses “should provide estimates of net benefits using [discount rates of] both 3 percent and 7 percent,” the agencies presented estimates of the proposed rule’s economic impacts—including the costs of climate damages likely to result from increased CO₂ emissions—that incorporated both discount rates. The PRIA included a detailed discussion of the analyses used to construct estimates of the domestic SC-CO₂ using these discount rates.¹⁸⁶²

The estimates of the domestic SC-CO₂ the agencies used in their analysis supporting the proposal increased over future years, partly because emissions during future years are anticipated to contribute larger incremental costs. Future values of the SC-CO₂ also increase because U.S. GDP is growing over time, and many categories of climate-related damage are estimates as proportions of GDP. The agencies’ estimates of the domestic SC-CO₂ for emissions occurring in the year 2020 were \$1 and \$8 (in 2016\$) per metric ton of CO₂ emissions using 7 and 3 percent discount rates, and these values were projected to increase to \$2 and \$10 (again in 2016\$) by the year 2050.

¹⁸⁶⁰ The guidance followed by EPA in developing the SC-CO₂ values used in the NPRM analysis appears in President of the United States, Executive Order 13783, “Promoting Energy Independence and Economic Growth,” March 28, 2017, Federal Register, Vol. 82, No. 61, Friday, March 31, 2017, 16093-97. (<https://www.govinfo.gov/content/pkg/FR-2017-03-31/pdf/2017-06576.pdf>) The recommendations of the National Academies are reported in National Academies of Sciences, Engineering, and Medicine, *Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide*, Washington, D.C., January 2017. Revised values incorporating this guidance have not yet been developed. <https://www.nap.edu/catalog/24651/valuing-climate-damages-updating-estimation-of-the-social-cost-of>

¹⁸⁶² See NHTSA and EPA, PRIA, Chapter 8, Appendix A.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

As the agencies indicated in the NPRM, the SC-CO₂ estimates are subject to several sources of uncertainty. In accordance with guidance provided by OMB Circular A-4 for treating uncertainty in regulatory analysis, the PRIA included a detailed discussion of how the analysis used to develop the interim SC-CO₂ estimates incorporated sources of uncertainty that could be quantified. It also demonstrated how considering the uncertainty introduced by applying discount rates over extended time horizons could affect the estimated values.¹⁸⁶³ To reflect this uncertainty, the analysis supporting the proposed rule examined the sensitivity of its estimated costs and benefits to using higher values for the SC-CO₂ (\$9-14 per metric ton), which were derived using a lower “intergenerational” discount rate of 2.5 percent.¹⁸⁶⁴

(a) *Comments on the NPRM Value for the SC-CO₂*

The agencies received extensive comments on the values of the SC-CO₂ used in the NPRM analysis. Broadly, these comments stressed the following concerns:

- Using a domestic value for SC-CO₂ systemically underestimates the benefits of adopting stricter standards.
- The agencies’ SC-CO₂ omits potential costs due to foreign social and political disruptions caused by climate change that can affect the U.S.
- The 7 percent discount rate used in the agencies’ main or central analysis is inappropriate because it represents an opportunity cost of capital rather than a rate of time preference for current versus future consumption opportunities, and climate change will affect future consumption.

(b) *Domestic vs. Global Value for SC-CO₂*

Many commenters asserted that it was inappropriate for the agencies to use a domestic SC-CO₂ value for analyzing benefits or costs from changing required levels of fuel economy in the NPRM analysis, primarily because doing so could lead regulatory agencies to adopt measures that provide inadequate reductions in emissions and protection from potential climate change.

As noted in the NPRM and above, the SC-CO₂ estimates the agencies used to estimate climate-related economic costs from adopting less demanding fuel economy and CO₂ emission were developed in response to the issuance of E.O. 13783. The agencies remind commenters that E.O. 13783 directed federal agencies to ensure that estimates of the social cost of greenhouse gases used in their regulatory analyses are consistent with the guidance contained in OMB Circular A-4, “including with respect to the consideration of domestic versus international impacts and the consideration of appropriate discount rates.”¹⁸⁶⁵ Circular A-4 states that analysis of economically significant proposed and final regulations “should focus on benefits and costs

¹⁸⁶³ See PRIA, Chapter 8, Appendix A.

¹⁸⁶⁴ PRIA, Tables 13-8 and 13-9, at 1547-50.

¹⁸⁶⁵ Executive Order 13,783, at 16096.

that accrue to citizens and residents of the United States.”¹⁸⁶⁶ The agencies adhered closely to this guidance in evaluating the economic costs and benefits in the proposal and this final rule by using the domestic value of the SC-CO₂ in our central analysis.

Commenters argued that Circular A-4 allows the agencies to use a global SC-CO₂ in their central analysis. For example, IPI et al. commented that “Circular A-4’s reference to effects ‘beyond the borders’ confirms that it is appropriate for agencies to consider the global effects of U.S. greenhouse gas emissions.”¹⁸⁶⁷ While the agencies agree that Circular A-4 authorizes the agencies to consider foreign impacts in certain circumstances, we also note that Executive Order 13783 stipulates “when monetizing the value of changes in greenhouse gas emissions resulting from regulations, including with respect to the consideration of domestic versus international impact [...] agencies shall ensure [...] any such estimates are consistent with the guidance contained in OMB Circular A-4.”¹⁸⁶⁸ Using a global SC-CO₂ in our central analysis would be inconsistent with Circular A-4’s directive that any non-domestic effects calculated “should be reported separately.”¹⁸⁶⁹ As such, if we had used a global SC-CO₂, we would be compelled by Circular A-4 to separate the SC-CO₂ into domestic and foreign components, and to include only the former in our central analysis.

Furthermore, today’s analysis will likely have global impacts beyond climate change. For example, freeing manufacturers who compete in the U.S. domestic automobile market from burdensome fuel efficiency standards may enable them to dedicate time and resources to becoming more competitive in global markets, and is thus likely to affect product innovation and performance throughout the global auto market.¹⁸⁷⁰ It would be inconsistent to report the global SC-CO₂ while ignoring other global costs and benefits. The agencies do not have a method for analyzing the comprehensive impacts of CAFE and GHG standards—including their many likely impacts beyond climate change—on a global scale, and did not receive any suggestions about how to conduct such an analysis from commenters. Because it would be inconsistent to quantify only climate change and none of these other potential global-scale impacts, the agencies have decided to focus their attention on domestic impacts, which are more readily measurable.

Several commenters argued that the agencies are still obligated to report the global impacts of carbon. For example, the North Carolina Department of Environmental Quality commented that “by omitting any analysis of the global social cost of carbon, [the agencies] failed to adhere to OMB’s Circular A-4.”¹⁸⁷¹ The agencies note Circular A-4 grants agencies

¹⁸⁶⁶ White House Office of Management and Budget, Circular A-4: Regulatory Analysis, September 17, 2003, at 15. (<https://www.whitehouse.gov/sites/whitehouse.gov/files/omb/circulars/A4/a-4.pdf>).

¹⁸⁶⁸ Executive Order 13,783, at 16096.

¹⁸⁶⁹ Specifically, OMB Circular A-4 directs federal agencies as follows: “Where you choose to evaluate a regulation that is likely to have effects beyond the borders of the United States, these effects should be reported separately.” OMB Circular A-4, at 15.

¹⁸⁷⁰ Some commenters assert that weakening U.S. fuel economy standards could make domestic auto companies *less* competitive in international markets, since several other nations have also adopted similar standards. For reasons discussed Section VIII.B.6. of this rule, however, the agencies find these comments unpersuasive.

¹⁸⁷¹ North Carolina Department of Environmental Quality, Comments, NHTSA-2018-0067-12025, at 39.

discretion to choose which impacts to report. However, to be fully informed of the gamut of potential effects of today's rule, the agencies have included two sensitivity cases analyzing the impacts of the standards using a global SC-CO₂.

(c) *Scope of Domestic Climate Damages*

Some commenters asserted that even if the agencies are required to use a domestic SC-CO₂, the specific value employed by the agencies underestimated the domestic impacts of climate change. They argued the agencies failed to incorporate economic costs associated with social or economic disruptions caused by climate change in regions of the world that were more vulnerable to its effects, but that could "spill over" to impose damages to the U.S. via their effects on migration patterns, international trade flows, or other mechanisms that connect nations. Other commenters argued that E.O. 13783 does not *prohibit* the agencies from using the estimates or practices developed by the IWG to develop new estimates of the SC-CO₂, and asserted that the IWG's methods and resulting estimates continue to represent the best available practices.

However, all of the IWG's estimates measure the global SC-CO₂, and as discussed previously, E.O. 13783, in conjunction with Circular A-4, directs the agencies to use a domestic SC-CO₂ which precludes the use of the IWG estimates. To develop interim estimates of the domestic SC-CO₂ that were consistent with the IWG's procedures, EPA used the same three climate economic models the IWG employed previously to calculate the domestic SC-CO₂. Two of those three models directly estimate the U.S. domestic SC-CO₂, which represents the economic costs resulting from climate change that are likely to be borne within U.S. borders.¹⁸⁷² The third model the IWG used previously does not estimate the domestic SC-CO₂ directly, but EPA approximated domestic U.S. costs from future climate change as 10 percent of its estimate of their global value, based on results from a companion model developed by the same author.¹⁸⁷³ Thus the agencies believed that the SC-CO₂ values they used in the NPRM analysis

¹⁸⁷² The Policy Analysis of the Greenhouse Effect (PAGE) model is described in Hope, C., "The marginal impact of CO₂ from PAGE2002: an integrated assessment model incorporating the IPCC's five reasons for concern," *The Integrated Assessment Journal*, Vol. 6 No. 1 (2006), at 19-56; and Hope, C., "Optimal carbon emissions and the social cost of carbon under uncertainty," *The Integrated Assessment Journal* Vol. 8, No. 1 (2008), at 107-22. The Climate Framework for Uncertainty, Negotiation, and Distribution (FUND) model is documented in Tol, Richard, "Estimates of the damage costs of climate change. Part I: benchmark estimates," and "Estimates of the damage costs of climate change. Part II: dynamic estimates." *Environmental and Resource Economics* Vol 21 (2002), at 47-73 and 135-60.

¹⁸⁷³ The third model is the Dynamic Integrated model of Climate and the Economy (DICE), described in Nordhaus, William, "Estimates of the Social Cost of Carbon: Concepts and Results from the DICE-2013R Model and Alternative Approaches." *Journal of the Association of Environmental and Resource Economists*, Vol. 1, No. 2 (2014), at 273-312 (<https://www.jstor.org/stable/pdf/10.1086/676035.pdf>). The 10 percent figure is based on the results from a regional version of that model (RICE 2010), as described in Nordhaus, William D. 2017, "Revisiting the social cost of carbon," *Proceedings of the National Academy of Sciences of the United States*, 114 (7), at 1518-23, Table 2. (https://pdfs.semanticscholar.org/f83b/3a7431e0ae2d4e8be3d0ee5f3787a802c34c.pdf?_ga=2.211824467.636056015.1572384992-158339427.1562696454).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

represented the most reliable estimates of domestic economic costs from future climate change that were available for use in evaluating the proposal.

The agencies were unable to develop an estimate of the domestic value for SC-CO₂ that incorporated any of these alleged spillover effects, due both to their speculative nature and to the absence of credible empirical estimates of their potential magnitude. Nor did commenters provide credible explanations for how such spillovers might arise, or reliable empirical estimates of their potential magnitude.

(d) *Discount Rate Used to Construct the SC-CO₂ Value*

Many commenters also objected to the agencies use of an SC-CO₂ value that incorporated a 7 percent discount rate in the NPRM analysis. Some of these comments reflected a misperception that the agencies used such a value in their main or central analysis, when in fact it was only used in a sensitivity analysis case as described below. Other comments appeared to object to the agencies' use of an SC-CO₂ value incorporating a 7 percent discount rate even as a sensitivity case.

E.O. 13783 directed agencies to ensure that any estimates of the social cost of CO₂ and other greenhouse gases they used for purposes of regulatory analyses are consistent with OMB Circular A-4's guidance "with respect to the consideration of...appropriate discount rates."¹⁸⁷⁴ In turn, Circular A-4 refers agencies to OMB's earlier guidance on discounting contained in its Circular A-94, noting that "[a]s a default position, OMB Circular A-94 states that a real discount rate of 7 percent should be used as a base-case for regulatory analysis."¹⁸⁷⁵ OMB continues to use the 7 percent rate to estimate the average pre-tax rate of return to private capital investment throughout the U.S. economy. Because it is intended to approximate the opportunity cost of capital, it is the appropriate discount rate for evaluating the economic consequences of regulations that affect private-sector capital investments.

At the same time, however, OMB's guidance on discounting also recognizes that some federal regulations are more likely to affect private consumption decisions made by households and individuals, such as when they affect prices or other attributes of consumer goods. In these cases, Circular A-4 advises that a lower discount rate is likely to be more appropriate, and that a reasonable choice for such a lower rate is the real consumer (or social) rate of time preference. This is the rate at which individual consumers discount future consumption to determine its present value to them.

OMB estimated that the rate of consumer time preference has averaged 3 percent in real or inflation-adjusted terms over an extended period, and continues to use that value. In summary, Circular A-4 reiterates the guidance provided in OMB's earlier Circular A-94 that

¹⁸⁷⁴ E.O. 13,783, at 16096.

¹⁸⁷⁵ OMB Circular A-4, at. 33.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

“[f]or regulatory analysis, you should provide estimates of net benefits using both 3 percent and 7 percent.”¹⁸⁷⁶

Finally, OMB’s guidance on discounting indicates that it may be appropriate for government agencies to employ an even lower rate of time preference when their regulatory actions entail tradeoffs between improving the welfare of current and future generations. Recognizing this situation, Circular A-4 advises if the “rule will have important intergenerational benefits or costs [an agency] might consider a further sensitivity analysis using a lower but positive discount rate in addition to calculating net benefits using discount rates of 3 and 7 percent.”¹⁸⁷⁷

The agencies adhered closely to each of these provisions of OMB’s guidance on discounting future climate-related economic costs in their analysis supporting the NPRM. Specifically, their central analysis relied exclusively on a SC-CO₂ value that was constructed by applying a 3 percent discount rate to future climate-related economic damages. This value ranged from \$6 per metric ton in 2015 to nearly \$11 per metric ton (both figures in 2016\$) by the end of the analysis period, the year 2050.

Throughout the NPRM central analysis, costs resulting from increased emissions of CO₂ were also discounted from the year when those increases in emissions occurred to the present using a 3 percent rate, even when all other future costs and benefits were discounted at a 7 percent rate. Thus the agencies’ central analysis for the NPRM did not use SC-CO₂ values for future years that were constructed by applying a 7 percent rate to discount distant future climate-related economic damages, and did not use a 7 percent rate to discount costs of increased CO₂ from the years when they were projected to occur to 2018 (the base year used in the analysis).

Notwithstanding concerns raised by commenters about including a sensitivity analysis that used a higher discount rate, OMB’s guidance clearly directs the agencies to report estimates of the present value of the economic costs resulting from increased CO₂ emissions that reflect discount rates of *both* 3 and 7 percent. Thus to supplement their central analysis, which as indicated previously employed a 3 percent discount rate throughout, the agencies also reported an estimate of the economic costs of increased CO₂ emissions based on a value for the SC-CO₂ that was constructed using a 7 percent discount rate as a sensitivity case, which they termed the “Low Social Cost of Carbon” sensitivity analysis.¹⁸⁷⁸ The values for the SC-CO₂ used in the Low Social Cost of Carbon sensitivity analysis varied from \$1 per metric ton in 2015 to \$3 per metric ton (both figures in 2016\$) by the end of the analysis period. Using these values reduced

¹⁸⁷⁶ OMB Circular A-4, at 34.

¹⁸⁷⁷ OMB Circular A-4, at 36.

¹⁸⁷⁸ PRIA, Table 13-1, at 1531-34.

the loss in total economic benefits resulting from the proposed alternative by 1.1 percent, thus increasing its net benefits by slightly less than 2 percent.¹⁸⁷⁹

For the proposal, the agencies also included a second sensitivity analysis using a value for the SC-CO₂ that reflected a lower “intergenerational” discount rate of 2.5 percent, which is within the 1 to 3 percent range for discount rates that have previously been applied to economic costs and benefits that span multiple generations, as reported in OMB guidance.¹⁸⁸⁰ Because using a lower discount rate results in a higher value for the SC-CO₂, this analysis was termed the “High Social Cost of Carbon” sensitivity case.¹⁸⁸¹ The values for the SC-CO₂ used in this additional sensitivity analysis varied from \$8 per metric ton in 2015 to \$14 per metric ton (both figures in 2016\$) in 2050, the last year of the analysis. Using these higher values increased the magnitude of the estimated loss in economic benefits resulted from adopting the proposed rule (versus retaining the Augural standards) by 0.5 percent from that estimated in the central analysis, thus reducing its net benefits by 1.0 percent.¹⁸⁸² Thus it appeared that when used to construct alternative estimates of the SC-CO₂, the range of discount rates specified in OMB Circular A-4 had little or no effect on the estimated total benefits of the proposed rule, and the sensitivity analyses conducted in support of this Final Rule confirm this result.¹⁸⁸³

(e) *SC-CO₂ for the Final Rule*

After carefully considering the concerns raised by commenters, the agencies decided to leave the SC-CO₂ values unchanged for the final rule. This means the SC-CO₂ estimate used in this analysis is still a domestic value that was constructed using a 3 percent discount rate, and that costs from increased CO₂ emissions are discounted from the year those emissions occur to the present using a 3 percent rate. The agencies have again included “High Social Cost of Carbon” and “Low Social Cost of Carbon” sensitivity analyses, which continue to use domestic SC-CO₂ values that incorporate alternative discount rates of 2.5 percent and 7 percent.

The agencies have also added two sensitivity cases using global values for the SC-CO₂, which reflect discount rates of 3 percent and 7 percent. Finally, the agencies have also included an additional sensitivity case that incorporates estimates of the domestic climate damage costs caused by emissions of the GHGs methane (CH₄) and nitrous oxide (N₂O). Like the SC-CO₂ values used in this analysis, the estimates of the domestic values for SC-CH₄ and SC-N₂O are

¹⁸⁷⁹ PRIA, Tables 13-8 and 13-9, at 1547-50. Using a lower value for the SC-CO₂ had opposite effects on the proposal’s total and net economic benefits, because its net benefits represented the difference between the loss in benefits and the savings in costs that would result from adopting the proposed rule, compared to the baseline of adopting the Augural standards.

¹⁸⁸⁰ OMB Circular A-4, at 36.

¹⁸⁸¹ PRIA, Table 13-1, at 1531-34.

¹⁸⁸² PRIA, Tables 13-8 and 13-9, at 1547-50. As in the Low Social Cost of Carbon sensitivity case, using a higher value for the SC-CO₂ had opposite effects on the total and net economic benefits, because its net benefits were the difference between the sacrifice in benefits and the savings in costs from adopting the proposed rule, where both were measured against the baseline of adopting the Augural standards.

¹⁸⁸³ See section VII.B. of this Final Rule for results of the “High Social Cost of Carbon” sensitivity case.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

interim estimates developed by EPA for use in regulatory analyses conducted under the guidelines specified in E.O 13783 and OMB Circular A-4, and incorporate a 3 percent discount rate.

(12) *External costs of congestion and noise*

(a) *Values used to analyze the proposal*

As explained in the proposal, changes in vehicle use affect the levels and economic costs of traffic congestion and highway noise associated with motor vehicle use.¹⁸⁸⁴ Congestion and noise costs are “external” to the vehicle owners whose decisions about how much, where, and when to drive more—or less—in response to changes in fuel economy result in these costs. Therefore, unlike changes in the costs incurred by drivers for fuel consumption or safety risks they willingly assume, changes in congestion and noise costs are not offset by corresponding changes in the travel benefits drivers experience.¹⁸⁸⁵

Congestion costs are limited to road users; however, since road users include a significant fraction of the U.S. population, changes in congestion costs are treated as part of the rule’s economic impact on the broader U.S. economy instead of as a cost or benefit to private parties. Costs resulting from road and highway noise are even more widely dispersed, because they are borne partly by surrounding residents, pedestrians, and other non-road users, and for this reason are also considered as a cost to the U.S. economy as a whole.

To estimate the economic costs associated with changes in congestion and noise caused by differences in miles driven, the analysis supporting the NPRM used estimates of per-mile congestion and noise costs from increased automobile and light truck use that were originally developed by FHWA as part of its 1997 Highway Cost Allocation Study.¹⁸⁸⁶ The agencies previously employed these same cost estimates in the 2010, 2011, and 2012 final rules.

The marginal congestion cost estimates reported in the 1997 FHWA study were intended to measure the costs of increased congestion resulting from incremental growth in travel by

¹⁸⁸⁴ The proposal estimated changes in congestion and noise costs associated with the overall change in vehicle use, which included changes in the use of new cars and light trucks associated with the fuel economy rebound effect as well as with changes in the use of older vehicles resulting from the effect of CAFE and CO₂ standards on turnover in the car and light truck fleets. As discussed in more detail elsewhere in this final rule, the current analysis assumes that total vehicle use (VMT) differs between the baseline and regulatory alternatives only because of changes in the use of cars and light trucks produced during the model years affected by this rule that occur in response to the fuel economy rebound effect.

¹⁸⁸⁵ The potential contribution of increased vehicle use to the costs of injuries and property damage caused by motor vehicle crashes may also be partly external to drivers who elect to travel more in response to the fuel economy rebound effect. However, these costs are dealt with directly and in more detail than the external costs of congestion and noise, in section VI.C.2. below.

¹⁸⁸⁶ Federal Highway Administration, 1997 Highway Cost Allocation Study, Chapter V, Tables V-22 and V-23, available at <https://www.fhwa.dot.gov/policy/hcas/final/five.cfm>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

different types of vehicles (including autos and light trucks), and the delays it causes to drivers, passengers, and freight shipments. As explained in the 1997 FHWA study, the distinction between marginal and average costs is extremely important in considering congestion costs on a per-vehicle-mile basis. Average congestion costs on a section of highway are calculated as the total congestion costs experienced by all vehicles, divided by total vehicle miles. In contrast, marginal congestion costs are calculated as the *increase* in congestion costs resulting from an incremental increase in vehicle miles.

Marginal congestion costs are significantly higher than average congestion costs because each additional vehicle that enters a crowded roadway slows travel speeds only slightly, thus adding only modestly to the *average* travel time of vehicles already on the road. During congested conditions, however, this modest increase is experienced by a very large number of vehicles, so the resulting increase in *total* delay experienced by all travelers using the road can be extremely large. As a consequence, the increases in total delay and congestion costs associated with additional driving are *more than* proportional to changes in VMT that cause them.¹⁸⁸⁷

The FHWA study's estimates of marginal noise costs reflected the variation in noise levels resulting from incremental changes in travel by autos, light trucks, and other vehicles, and the annoyance and other adverse impacts caused by noise. These included adverse impacts on pedestrians and residents of the surrounding area, as well as on vehicle occupants themselves.

To calculate the incremental costs of congestion and noise, the agencies multiplied FHWA's "middle" estimates of marginal congestion and noise costs per mile of auto and light truck travel in urban and rural areas by the annual increases in driving attributable to the standards to yield increases in total congestion and noise externality costs. Because the proposal, and other alternatives that were considered, reduced the stringency of CAFE and CO₂ standards for model years 2021-2026, resulting in lower fuel economy for new cars and light trucks produced during those years, the fuel economy rebound effect resulted in *fewer* miles driven relative to the baseline, thus generating savings in congestion and noise costs relative to their levels under the baseline. Similarly, each of those alternatives also reduced the total amount of travel by the used vehicle fleet, generating additional savings in these costs.

(b) *Comments on the NPRM values*

The agencies received few comments on the estimates of congestion and noise costs they used to analyze the economic impacts of the proposal. Almost all of these comments focused on the appropriateness of the estimated magnitude of the fuel economy rebound effect they used to estimate the change in use of new cars and light trucks or the plausibility of the reduction in

¹⁸⁸⁷ Such "non-linearity" is a common feature of complex systems, such as computing or juggling. Each additional element added to a computation, or ball to a cascade, makes performing the task more difficult than the last addition.

driving by used vehicles, rather than to the unit costs estimates themselves. These included comments from ICCT and CARB.¹⁸⁸⁸

One individual commenter did suggest that recent growth in traffic levels, resulting in part from increased use of home delivery services for online purchases, has increased congestion and resulting delays.¹⁸⁸⁹ Although this commenter is correct, traffic growth is not strictly a recent phenomenon, and longer-term growth in vehicle use—combined with comparatively modest increases in road and highway capacity—has contributed to increasing congestion levels. Because congestion increases more than proportionately to growing traffic volumes, this suggests that FHWA’s estimates of congestion costs—now more than two decades old—are likely to understate the contribution of continuing increases in vehicle use to congestion, resulting delays to vehicle occupants and freight shipments, and their associated costs. Because noise levels also increase non-linearly with the volume of traffic using roads and highways, FHWA’s 1997 estimates of marginal noise costs may also understate current values.

(c) *Values used to analyze the final rule*

The agencies are retaining the same methodology employed in the NPRM to estimate congestion and noise costs for the final rule. Like other nominal estimates used throughout the analysis, the agencies have updated the FHWA estimates to account for current economic and highway conditions. The major determinants of marginal congestion costs imposed by additional travel include baseline traffic volumes, which determine current travel speeds and how they would change in response to further increases in travel, together with vehicle occupancy and the value of occupants’ travel time. These last two factors interact to determine the average hourly value of delays to vehicles, which is by far the largest component of the total cost of delays that occur under congested travel conditions.¹⁸⁹⁰ Because travel speeds measure the duration of congestion-related delays, while the value of vehicle occupants’ time determines their hourly cost, the effects of changes in these variables on overall congestion costs is approximately additive, as long as changes in the two are relatively modest.

The agencies approximated the effect of growth in traffic volumes on travel speeds and congestion-related delays by increasing congestion costs in proportion to the increase in annual vehicle-miles of travel per lane-mile on major U.S. highways that occurred between 1997 and 2017.¹⁸⁹¹ Next, they estimated the increase in the value of travel time per vehicle-hour over that same period by combining growth in the value of travel time per person-hour—estimated in

¹⁸⁸⁸ ICCT, Comment, NHTSA-2018-0067-11741 at 121; CARB, Comment, NHTSA-2018-0067-11873 at 316.

¹⁸⁸⁹ Richard Carriere, NHTSA-2018-0067-12216.

¹⁸⁹⁰ Fuel consumption and other operating costs can also increase during travel in congested conditions, but their relationships to the frequent changes in speed that typically occur in congested travel is less well understood, and in any case, they vary by far smaller amounts than the value of vehicle occupants’ travel time.

¹⁸⁹¹ Traffic volumes, as measured by the annual number of vehicle-miles traveled per lane-mile of roads and highways nationwide, rose by 53 percent between 1997 and 2017. Calculated from FHWA, Highway Statistics, 1998 and 2018, Tables VM-1 and HM-48, available at <https://www.fhwa.dot.gov/policyinformation/statistics.cfm>.

accordance with DOT guidance¹⁸⁹²—with the increase in average vehicle occupancy by persons 16 years of age and older (the same measure of occupancy used to estimate the value of refueling time elsewhere in this analysis).¹⁸⁹³ The agencies applied the increases in congestion-related delays and the hourly value of travel time to FHWA’s 1997 estimates of marginal congestion costs to update those original values to reflect current conditions. The updated values of external congestion costs are \$0.154 per vehicle-mile of increased travel by cars and \$0.138 per vehicle-mile for light trucks (expressed in constant 2018 dollars), and these values are assumed to remain constant throughout the analysis period.

Similarly, the agencies revised the FHWA estimate of marginal noise costs by adjusting for inflation—since the 1994 base year used to express values in the FHWA study. Because marginal noise costs are so small—less than \$0.001 per mile of travel for both cars and light trucks—this change did not have a significant impact on the agencies’ estimates of benefits and costs from the final rule.

(13) *Labor utilization assumptions*

In previous joint CAFE/CO₂ rulemakings, the agencies considered employment impacts on the automobile manufacturing industry, but many of the considerations were qualitative. In the NPRM, the agencies presented and took comment on a methodology to quantify roughly the direct labor utilization impacts. The agencies recognize there is significant uncertainty in any forward-looking characterization of labor utilization, including effects resulting from CAFE/CO₂ rulemakings. Changes to other policies such as trade policies and tariff policies are likely substantially to alter underlying assumptions presented in the analysis for the rulemaking, and these changes could dwarf any differences between policy alternatives presented. In this section the agencies discuss the assumptions made in the NPRM analysis, summarize comments received on that work, and respond to these comments.

(a) *Labor utilization baseline (including multiplier effect) and data description*

In prior CAFE/CO₂ rulemakings, the agencies considered an analysis of employment impacts in some form in setting both CAFE and tailpipe CO₂ emissions standards; NHTSA conducted an employment analysis in part to determine whether the standards the agency set were economically practicable, that is, whether the standards were “within the financial

¹⁸⁹² See U.S. Department of Transportation, “Revised Departmental Guidance for the Valuation of Travel Time in Economic Analysis,” 2016, at 5-6 and Table 1 at 13.

¹⁸⁹³ The average hourly value of travel time increased by 82 percent between 1997 and 2017; see U.S. Department of Transportation, “Departmental Guidance for the Valuation of Travel Time in Economic Analysis,” April 9, 1997, Table 4, and U.S. Department of Transportation, “Benefit-Cost Analysis Guidance for Discretionary Grant Programs,” December 2018, Table A-3. From 1995 to 2017, the average number of light-duty vehicle occupants 16 years of age and older increased by 18 percent; values were tabulated from FHWA, Nationwide Personal Transportation Survey, 2005 and 2017, using online table designer available at <https://nhts.oml.gov/> and <https://nhts.oml.gov/index9.shtml>.

capability of the industry, but not so stringent as to” lead to “adverse economic consequences, such as a significant loss of jobs or unreasonable elimination of consumer choice.”¹⁸⁹⁴ EPA similarly conducted an employment analysis under the authority granted to the agency under the Clean Air Act.¹⁸⁹⁵ Both agencies recognized the uncertainties inherent in estimating employment impacts; in fact, both agencies dedicated a substantial amount of discussion to uncertainty in employment analyses in the 2012 final rule for MYs 2017 and beyond.¹⁸⁹⁶ Notwithstanding these uncertainties, by imposing costs on new light duty vehicles, CAFE and CO₂ standards can have an impact on the demand for labor. Providing the best analysis practicable better informs stakeholders and the public about the standards’ impact than would omitting any estimates of potential labor impacts.

The NPRM quantified many of the effects that were previously qualitatively identified, but not considered. For instance, in the PRIA for the 2017-2025 rule EPA identified “demand effects,” “cost effects,” and “factor shift effects” as important considerations for labor, but the analysis did not attempt to quantify each of these effects.¹⁸⁹⁷

The NPRM analysis considered direct labor effects on the automotive sector. The NPRM evaluated how labor utilization in different facets of the automobile manufacturing industry may be affected by the rule, including (1) dealership labor related to new light-duty vehicle unit sales; (2) assembly labor for vehicles, for engines and for transmissions related to new vehicle unit sales; and (3) labor related to mandated additional fuel savings technologies, accounting for new vehicle unit sales. Importantly, this analysis did not consider whether price reductions and regulatory savings associated with different standards would, because price reductions would allow consumers to save or spend that money on other things of value, increase the consumption of other vehicle technologies or, more generally, generate growth in other sectors of the overall economy. This means that the analysis is inherently and artificially narrow in its focus, and does not represent an attempt to quantify the overall labor or economic effects of this rulemaking. All labor effects were estimated and reported at a national level, in person-years, assuming 2,000 hours of labor per person-year.¹⁸⁹⁸

The NPRM analysis estimated labor effects from the forecasted CAFE model technology costs and from review of automotive labor for the MY 2016 fleet. For each vehicle in the CAFE model analysis, the locations for vehicle assembly, engine assembly, and transmission assembly and estimated labor in MY 2016 were recorded. The percent of U.S. content for each vehicle

¹⁸⁹⁴ 67 FR 77015, 77021 (Dec. 16, 2002).

¹⁸⁹⁷ U.S. EPA, “Regulatory Impact Analysis: Final Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards,” at 8-24 to 8-32 (Aug. 2012).

¹⁸⁹⁸ The agencies recognize a few local production facilities may contribute meaningfully to local economies, but the analysis reported only on national effects.

was also recorded.¹⁸⁹⁹ The analysis also took into account the portion of parts that are made in the U.S. by holding constant the percent of U.S. content for each vehicle as manufacturers add fuel-savings technologies. The analysis further assumes that the U.S. labor added would be proportional to U.S. content, which means that the analysis assumes that U.S. labor inputs would remain constant over time, but this does not reflect a prediction that U.S. labor inputs actually will remain constant.¹⁹⁰⁰ From this foundation, the analysis forecasted automotive labor effects as the CAFE model added fuel economy technology and adjusted future sales for each vehicle.

The NPRM analysis also accounted for sales projections in response to the different regulatory alternatives; the labor analysis considers changes in new vehicle prices and new vehicle sales (for further discussion of the sales model, see Section VI.D.1.b.xii). As vehicle prices rise, the analysis expected consumers to purchase fewer vehicles than they would have at lower prices.¹⁹⁰¹ As manufacturers sell fewer vehicles, the manufacturers may need less labor to produce the vehicles and dealers may need less labor to sell the vehicles. However, as manufacturers add equipment to each new vehicle, the industry will require labor resources to develop, sell, and produce additional fuel-saving technologies. The analysis also accounted for the possibility that new standards could shift the relative shares of passenger cars and light trucks in the overall fleet (see Section VI.1.A.2.b); insofar as different vehicles involved different amounts of labor, this shifting impacts the quantity of estimated labor. The labor analysis took into account the anticipated reduction in vehicle sales, shifts in the mix of passenger cars and light trucks, and addition of fuel-savings technologies that result from the regulation—and, subsequently, the anticipated increase in sales and reduction of fuel-savings technologies that are expected to result from a reduction in stringency.

For the NPRM analysis, the agencies assumed that some observations about the production of MY 2016 vehicles would carry forward, unchanged into the future. For instance, assembly plants would remain the same as MY 2016 for all products now, and in the future. The analysis assumed the percent of U.S. content would remain constant, even as manufacturers updated vehicles and introduced new fuel-saving technologies. The analysis further assumed that assembly labor hours per unit would remain at estimated MY 2016 levels for vehicles, engines, and transmissions, and the factor between direct assembly labor and parts production labors would remain the same. When considering shifts from one technology to another, the analysis assumed revenue per employee at suppliers and original equipment manufacturers would remain in line with MY 2016 levels, even as manufacturers added fuel-saving technologies and realized cost reductions from learning.

¹⁸⁹⁹ NHTSA provides reports under 49 CFR Part 583, “American Automobile Labeling Act Reports” with information NHTSA received from vehicle manufacturers about the U.S./Canadian content (by percentage value) of the equipment (parts) used to assemble passenger motor vehicles. See <https://www.nhtsa.gov/part-583-american-automobile-labeling-act-reports>.

¹⁹⁰⁰ This is a key assumption that should be revisited as trade deals and tax or tariff policies materially change.

¹⁹⁰¹ Many commenters contend that higher prices for more efficient goods will have no effect on unit sales and hence necessary production resources and employment. The sales aspect of labor utilization is addressed in the sales section. NHTSA-2018-0067-12000-35, Center for Biological Diversity, et al.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The NPRM analysis focused on automotive labor because adjacent employment factors and consumer spending factors for other goods and services are uncertain and difficult to predict. The analysis did not consider how direct labor changes may affect the macro economy and possibly change employment in adjacent industries. For instance, the analysis did not consider possible labor changes in vehicle maintenance and repair, nor did it consider changes in labor at retail gas stations. The analysis did not consider possible labor changes due to raw material production, such as production of aluminum, steel, copper, and lithium, nor did the agencies consider possible labor impacts due to changes in production of oil and gas, ethanol, and electricity. The analysis did not analyze potential labor effects arising from consumption of other products that would not have occurred but for improved fuel economy, nor did the analysis assess the effects arising from reduced consumption of other products that results from more expensive fuel savings technologies at the time of purchase. The effects of increased usage of car-sharing, ride-sharing, and automated vehicles were not analyzed. The analysis did not estimate how changes in labor from any of these industries could affect gross domestic product and possibly affect other industries as a result.

Many commenters voiced concerns that the NPRM analysis only included automotive direct employment, and did not explicitly consider other important factors, and that these factors would be better addressed with a macroeconomic model. For instance, the International Council on Clean Transportation contended that the dollars saved at the pump as a result of fuel saving technologies would be spent elsewhere in the economy, creating jobs.¹⁹⁰² The Association of Global Automakers also referenced macroeconomic studies that project long-term job gains due to savings at the pump, but also highlight short-term setbacks for jobs as money spent to purchase additional fuel saving technologies on new vehicles is not spent in other job creating sectors of the U.S. economy, which were not considered in an analysis that only addresses direct automotive employment.¹⁹⁰³ The Union of Concerned Scientists and Environmental Defense Fund argued that the modeling of short-term job losses in the macroeconomic models is incorrect, and that purchasing a new vehicle, especially if financed, should *increase* disposable income, because monthly savings at the pump outpace the monthly financed cost of the fuel saving equipment, but also that consumers will not choose this equipment unless a stringent standard is chosen.¹⁹⁰⁴ The Institute for Policy Integrity commented that an analysis looking only at direct employment is incomplete, and encouraged the agencies to include long-term and economy-wide effects in scope on employment discussions.¹⁹⁰⁵

The agencies have not quantified employment effects outside of automotive sector direct employment for this final rule. The agencies agree with commenters that the reductions in production costs of new vehicles will free up resources for other productive pursuits. Some producers may shift resources away from the development and production of fuel saving technologies and into the development and production of other vehicle attributes. In this case,

there would be a transfer of labor resources within a firm. Other producers may instead pass along the reduction in production costs to consumers in the form of price reductions or avoided price increases, allowing those consumers to allocate those new funds between expenditure in other consumption categories or savings. The increased expenditure in other consumption categories would more efficiently create new employment in sectors expanding to cover new market-based (as opposed to regulatory-based) demand. Increased savings also creates additional investment in new productive capital, which will generate employment opportunities in the future. However, the extent and nature of these effects are all highly uncertain, and the agencies have therefore not quantified the effect of the rule on economy-wide employment in the final rule analysis.

Many commenters expressed concern that America would cede leadership in development and production of fuel saving technologies, and fuel-saving technology investment would be gutted if augural standards were not kept in place. For instance, the Mayor of the City of Chillicothe, and Mayors of other Ohio cities, pointed out that many light duty vehicles are built in Ohio and neighboring geographies, and that workers designing and producing fuel economy equipment make an average annual salary of \$61,500, expressing concern that if standards are lowered, some of these jobs may no longer be necessary.¹⁹⁰⁶ The BlueGreen Alliance pointed out that over the last twenty years, manufacturers have invested billions of dollars into fuel saving technologies, and that multinational companies may shift jobs to other countries if the standards do not require continued, strong, additional investment in even more fuel saving technologies.¹⁹⁰⁷

The agencies recognize that development of fuel saving technologies can be capital intensive. However, high fuel economy standards do not, per se, guarantee multinational companies will invest in American research and development or production. For example, the larger percent U.S. content in the MY 2017 light truck vs. the MY 2017 passenger car new vehicle fleet may be tied to the so-called “Chicken Tax,” a long-established tariff on the import of light duty trucks.¹⁹⁰⁸ On average, a light truck in the MY 2017 fleet contained 47.8 percent U.S. content, while a passenger car contained 36.0 percent U.S. content. To the extent that other policies encourage multi-national corporations to build and invest in U.S. production facilities, these organizations will need access to capital to do so. Notably, as part of the sales module, as fuel economy of the fleet improves, the agencies assume customers increasingly choose light trucks, meaning that a shift towards light-trucks is already considered in the CAFE model under the augural standards.

¹⁹⁰⁶ NHTSA-2018-0067-12318-2, Mayors of the City of Chillicothe and other Ohio cities.

¹⁹⁰⁷ NHTSA-2018-0067-12009-6, BlueGreen Alliance.

¹⁹⁰⁸ On average, a light truck in the MY 2017 fleet contained 47.8 percent U.S. content, while a passenger car contained 36.0 percent U.S. content.

Figure II-4374 – MY 2017 Sales Weighted Percent U.S. Parts Content by Regulatory Class

Finally, no assumptions were made about part-time-level of employment in the broader economy and the availability of human resources to fill positions. When the economy is at full employment, a fuel economy regulation is unlikely to have much impact on net overall U.S. employment; instead, labor would primarily be shifted from one sector to another. These shifts in employment impose an opportunity cost on society, as regulation diverts workers from other market-based activities in the economy. In this situation, any effects on net employment are likely to be transitory as workers change jobs (e.g., some workers may need to be retrained or require time to search for new jobs, while short-term labor shortages in some sectors or regions could result in firms bidding up wages to attract workers). On the other hand, if a regulation comes into effect during a period of less-than-full employment, a change in labor demand due to regulation would affect net overall U.S. employment because the labor market is not in equilibrium. Schmalensee and Stavins point out that net positive employment effects are possible in the near term when the economy is at less than full employment due to the potential hiring of idle labor resources by the regulated sector to meet new requirements (e.g., to install new equipment) and new economic activity in sectors related to the regulated sector longer run.¹⁹⁰⁹ However, the net effect on employment in the long run is more difficult to predict and will depend on the way in which the related industries respond to regulatory requirements. For that reason, this analysis does not include multiplier effects but instead focuses on labor impacts in the most directly affected industries, which would face the most concentrated labor impacts.

¹⁹⁰⁹ Schmalensee, Richard, and Robert N. Stavins. "A Guide to Economic and Policy Analysis of EPA's Transport Rule." White paper commissioned by Excelon Corporation, March 2011 (Docket EPA-HQ-OAR-2010-0799-0676).

(b) *Estimating labor for fuel economy technologies, vehicle components, final assembly, and retailers*

The following sections discuss the approaches to estimating factors related to dealership labor, final assembly labor and parts production, and fuel economy technology labor.

(i) Dealership Labor

The NPRM analysis evaluated dealership labor related to new light-duty vehicle sales, and estimated the labor hours per new vehicle sold at dealerships, including labor from sales, finance, insurance, and management. The effect of new car sales on the maintenance, repair, and parts department labor is expected to be limited, as this need is based on the vehicle miles traveled of the total fleet. To estimate the labor hours at dealerships per new vehicle sold, the agencies referenced the National Automobile Dealers Association 2016 Annual Report, which provides franchise dealer employment by department and function.¹⁹¹⁰ The analysis estimated that slightly less than 20 percent of dealership employees' work relates to new car sales (versus approximately 80 percent in service, parts, and used car sales), and that on average dealership employees working on new vehicle sales labor for 27.8 hours per new vehicle sold. The analysis presented today retains assumptions about dealership labor hours per vehicle sold.

(ii) Final assembly labor and parts production

As new vehicle sales increase or decrease, the amount of labor required to assemble parts and vehicles changes accordingly. The NPRM evaluated how the quantity of assembly labor and parts production labor for MY 2016 vehicles would increase or decrease in the future as new vehicle unit sales increased or decreased. Specific assembly locations for final vehicle assembly, engine assembly, and transmission assembly for each MY 2016 vehicle were identified. In some cases, manufacturers assembled products in more than one location, and the analysis identified such products and considered parallel production in the labor analysis.

The analysis estimated average direct assembly labor per vehicle (30 hours), per engine (four hours), and per transmission (five hours) based on a sample of U.S. assembly plant employment and production statistics and other publicly available information. The analysis used the assembly locations and averages for labor per unit to estimate U.S. assembly labor hours for each vehicle. U.S. assembly labor hours per vehicle ranged from as high as 39 hours if the manufacturer assembled the vehicle, engine, and transmission at U.S. plants, to as low as zero hours if the manufacturer imported the vehicle, engine, and transmission.

The analysis also considered labor for parts production. The agencies surveyed motor vehicle and equipment manufacturing labor statistics from the U.S. Census Bureau, the Bureau of Labor Statistics, and other publicly available sources. The agencies found that the historical

¹⁹¹⁰ NADA Data 2016: Annual Financial Profile of America's Franchised New-Car Dealerships, National Automobile Dealers Association, <https://www.nada.org/2016NADAdat/> (last visited December 20, 2019).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

average ratio of vehicle assembly manufacturing employment to employment for total motor vehicle and equipment manufacturing for new vehicles was roughly constant over the period from 2001 through 2013, at a ratio of 5.26.¹⁹¹¹ Observations from 2001-2013 included many combinations of technologies and technology trends, and many economic conditions, yet the ratio remained about the same over time. Accordingly, the analysis scaled up estimated U.S. assembly labor hours by a factor of 5.26 to consider U.S. parts production labor in addition to assembly labor for each vehicle. The estimates for vehicle assembly labor and parts production labor for each vehicle scaled up or down as unit sales scaled up or down over time in the CAFE model.

The analysis presented today retains assumptions about coefficients for final assembly labor and parts production, and updates production and final assembly locations for the MY 2017 fleet. As discussed in Section VI.B.1.b.xii, today's analysis also applies updated methods for estimating the extent to which changes in CAFE and CO₂ standards might lead to changes in quantities of new vehicles sold each year. These estimated changes in sales lead to changes in estimated changes in domestic employment.

(iii) Fuel economy technology labor

As manufacturers spend additional dollars on fuel-saving technologies, parts suppliers and manufacturers require labor to bring those technologies to market. Manufacturers may add, shift, or replace employees in ways that are difficult for the agencies to predict; however, it is expected that the revenue per labor hour at original equipment manufacturers (OEMs) and suppliers will remain about the same as in MY 2016 even as manufacturers include additional fuel-saving technology. To estimate the average revenue per labor hour at OEMs and suppliers, the analysis looked at financial reports from publicly traded automotive businesses.¹⁹¹² Based on recent figures, it was estimated that OEMs would add one labor year per each \$633,066 increment in revenue and that suppliers would add one labor year per \$247,648 in revenue.¹⁹¹³ These global estimates are applied to all revenues, and U.S. content is applied as a later adjustment. In today's analysis, the agencies assume these ratios would remain constant for all technologies rather than that the increased labor costs would be shifted toward foreign countries. There are some reasons to believe that this may be a conservative assumption. For instance, domestic manufacturers may react to increased labor costs by searching for lower-cost labor in other countries.

¹⁹¹¹ NAICS Code 3361, 3363.

¹⁹¹² The analysis considered suppliers that won the Automotive News "PACE Award" from 2013-2017, covering more than 40 suppliers, more than 30 of which are publicly traded companies. Automotive News gives "PACE Awards" to innovative manufacturers, with most recent winners earning awards for new fuel-savings technologies.

¹⁹¹³ The analysis assumed incremental OEM revenue as the retail price equivalent for technologies, adjusting for changes in sales volume. The analysis assumed incremental supplier revenue as the technology cost for technologies before retail price equivalent mark-up, adjusting for changes in sales volume.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The analysis presented today retains assumptions about coefficients for fuel economy technology labor, and updates the percent of U.S. content for the MY 2017 fleet.

(iv) Labor Calculations

The agencies estimated the total labor effect as the sum of three components: changes to dealership hours, final assembly and parts production, and labor for fuel-economy technologies (at OEMs and suppliers) that are due to the final rule. The CAFE model calculated additional labor hours for each vehicle, based on current vehicle manufacturing locations and simulation outputs for additional technologies, and sales changes. The analysis applied some constants to all vehicles.¹⁹¹⁴ Other constants were vehicle specific, for all years considered in the analysis.¹⁹¹⁵ Still, other constants were year-specific for a vehicle.¹⁹¹⁶ While a multiplier effect of all U.S. automotive related labor on non-auto related U.S. jobs was not considered for the final rule's analysis, the analysis did incorporate a "global multiplier" that can be used to scale up or scale down the total labor hours. This parameter exists in the parameters file, and for the final rule's analysis the analysis set the value at 1.00. The results of this analysis can be found in [Table II-94](#)~~Table VI-172~~ below.

Table II-~~94~~¹⁶⁷ – Work Loss Days through MY 2029

				Alternative			
	1	2	3	4	5	6	7
Model Years	2021-2026	2021-2026	2021-2026	2021-2026	2022-2026	2021-2026	2022-2026
Annual Rate of Stringency Increase	0.0%/Year PC 0.0%/Year LT	0.5%/Year PC 0.5%/Year LT	1.5%/Year PC 1.5%/Year LT	1.0%/Year PC 2.0%/Year LT	1.0%/Year PC 2.0%/Year LT	2.0%/Year PC 3.0%/Year LT	2.0%/Year PC 3.0%/Year LT
Work Loss Days (thousand instances) through MY2029	89.61	87.55	45.36	36.38	19.91	-12.46	3.58

Results of this analysis can be found in Section VII. Considering that, all else equal, increases in new vehicle sales lead to increases in domestic employment while decreases in technology outlays lead to decreases in domestic employment, the agencies estimate that less stringent standards could slightly reduce domestic employment. It is important to note, however, that the reduction in person-years described in this table merely reflects the fact that, when compared to the standards set in 2012, fewer jobs will be specifically created to meet infeasible

¹⁹¹⁴ The analysis applied the same assumptions to all manufacturers for annual labor hours per employee, dealership hours per unit sold, OEM revenue per employee, supplier revenue per employee, and factor for the jobs multiplier.

¹⁹¹⁵ The analysis made vehicle-specific assumptions about percent of U.S. content and U.S. assembly employment hours.

¹⁹¹⁶ The analysis estimated technology cost for each vehicle, for each year based on the technology content applied in the CAFE model, year-by-year.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

regulatory requirements. It is also important to note that avoided outlays for technology can be invested by manufacturers into other areas, or passed on to consumers. Moreover, consumers can either take those cost savings in the form of a reduced vehicle price, or used toward the purchase of specific automotive features that they desire (potentially including a more-efficient vehicle), which would increase employment among suppliers and manufacturers.

2. Simulating safety impacts of regulatory alternatives

The primary objectives of CAFE and CO₂ standards are to achieve maximum feasible fuel economy and reduce CO₂ emissions, respectively, from the light-duty vehicle fleet. In setting standards to achieve these intended effects, the potential of the standards to affect vehicle safety is also considered. As a safety agency, NHTSA has long considered the potential for adverse safety consequences when establishing CAFE standards, and under the CAA, EPA considers factors related to public health and human welfare, including safety, in regulating emissions of air pollutants from mobile sources.

Safety trade-offs associated with increases in fuel economy standards have occurred in the past—particularly before CAFE standards became attribute-based—because manufacturers chose to comply with stricter standards by building smaller and lighter vehicles. In cases where fuel economy improvements were achieved through reductions in vehicle size and mass, the smaller, lighter vehicles did not protect their occupants as effectively in crashes as larger, heavier vehicles, on average. Although the agencies now use attribute-based standards, in part to reduce the incentive to downsize vehicles to comply with CAFE and CO₂ standards, the agencies must continue to be mindful of the possibility of safety-related trade-offs.

Although prior analyses acknowledged that CAFE and CO₂ standards could influence factors that affect safety other than vehicle mass, those impacts were not estimated quantitatively.¹⁹¹⁷ Instead, the agencies focused exclusively on the safety impacts of changes in vehicle mass. In the proposal, the safety analysis was expanded to include a broader and more comprehensive measure of safety impacts. The final rule retains this comprehensive approach and analyzes the safety impact of three factors:

- 1) **Changes in Vehicle Mass.** Similar to previous analyses, the agencies calculate the safety impact of changes in vehicle mass made to reduce fuel consumption and comply with the standards. The agencies' statistical analysis of historical crash data indicates reducing mass in heavier vehicles generally improves safety, while reducing

¹⁹¹⁷ The agencies included a quantification of rebound-associated safety impacts in its Draft TAR analysis, but because the scrappage model is new for this rulemaking, did not include safety impacts associated with the effect of standards on new vehicle prices and thus on fleet turnover. The fact that the scrappage model did not exist prior to this rulemaking does not mean that the effects that it aims to show were not important considerations, simply that the agencies were unable to account for them quantitatively prior to the current rulemaking.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

mass in lighter vehicles generally reduces safety. NHTSA's crash simulation modeling of vehicle design concepts for reducing mass revealed similar effects.

- 2) **Impacts of Vehicle Prices.** Vehicles have become safer over time through a combination of new safety regulations and voluntary safety improvements. The agencies expect this trend to continue as emerging technologies, such as advanced driver assistance systems, are incorporated into new vehicles. Safety improvements will likely continue regardless of changes to CAFE standards. However, the pace of such improvements may be modified if manufacturers choose to delay or forgo investments in safety technology because of the demands that complying with stricter CAFE and CO₂ standards impose on scarce research, development, and manufacturing resources.

As discussed in Section VI.D.1.b, technologies added to comply with fuel economy standards have an impact on vehicle prices, and, by extension, on the affordability of newer, safer vehicles, and therefore on the rates at which newer vehicles are acquired and older, less safe vehicles are retired from use. The delays in fleet turnover caused by the effect of new vehicle prices on sales and scrappage rates affect safety, by slowing the penetration of new safety technologies into the fleet.

The standards also influence the composition of the light-duty fleet. As the safety provided by light trucks, SUVs and passenger cars responds differently to technology that manufacturers employ to meet the standards—particularly mass reduction—fleets with different compositions of body styles will have varying numbers of fatalities, so changing the share of each type of light-duty vehicle in the projected future fleet impacts safety outcomes.

- 3) **Increased driving because of better fuel economy.** The “rebound effect” predicts consumers will drive more when the cost of driving declines. More stringent standards reduce vehicle operating costs, and in response, some consumers may choose to drive more. Additional driving increases exposure to risks associated with motor vehicle travel, and this added exposure translates into higher fatalities and injuries.

We measure the impact of these factors as differences in fatalities across the alternatives. Fatalities are calculated by deriving a fleet-wide fatality rate (fatalities per vehicle mile of travel) incorporating the different factors and multiplying it by the alternative's expected VMT. Fatalities are converted into a societal cost by multiplying fatalities with the DOT-recommended value of a statistical life (VSL). As with the NPRM, traffic injuries and property damage are not modeled directly;¹⁹¹⁸ rather, traffic injuries and property damage continue to be estimated using

¹⁹¹⁸ The agencies noted in the NPRM that traffic injuries and property damage are not directly modeled because of insufficient data. See PRIA at 43108.

adjustment factors that reflect the observed relationship between societal costs of fatalities and costs of injuries and property damage.

All three factors influence predicted fatalities, but only two of them—changes in vehicle mass and in the composition of the light-duty fleet in response to changes in vehicle prices—impose increased risks on drivers and passengers that are not compensated for by accompanying benefits. In contrast, increased driving associated with the rebound effect is a consumer choice that reveals the benefit of additional travel. Consumers who choose to drive more have apparently concluded that the utility of additional driving exceeds the additional costs for doing so—including the crash risk that they perceive additional driving involves. As discussed in Section VI.D.2.c), we account for the benefits of rebound driving by offsetting a portion of the added safety costs.

Some commenters argued that the agencies should be measuring the change in the fatality *rate* rather than the change in the number of fatalities. For example, EDF argued that changes in fatalities was a measurement of VMT and number of passengers rather than safety, and that “NHTSA’s job is to decrease the fatality rate per mile, not to decrease the number of miles people drive.”¹⁹¹⁹ EDF also commented that the agencies were required to report the “fatality rate data for the overall safety impacts.” The agencies disagree with EDF. The agencies are responsible for measuring the impacts of fuel economy and CO₂ standards, including changes to VMT. While other NHTSA safety rules have minimal impacts upon aggregate VMT, CAFE standards have a large impact on VMT and VMT-related costs, including fatalities.

Although NHTSA often uses changes in fatality rates as a metric to evaluate the impact of regulations on safety, these rates are just a tool utilized to derive the relevant safety impact—namely the estimated change in fatalities. Furthermore, as part of the cost-benefit analysis required by Executive Order 12866 and specified in OMB Circular A-4, the agencies must quantify and value safety impacts to compare them to the costs of the regulation. The fundamental metric for valuing loss of life is the VSL. To apply this metric, the agencies must first produce estimates of any change in the number of fatalities that results from the regulatory action. Fatalities prevented, as well as other safety impacts such as non-fatal injuries prevented and property damage crashes avoided, are appropriate measures of rules that affect motor vehicle safety.

a) Impact of Weight Reduction on Safety

Vehicle mass reduction can be one of the more cost-effective means of increasing fuel economy and reducing CO₂ emissions to meet standards—particularly for makes and models not already built with much high strength steel or aluminum closures or low mass components. Manufacturers have stated that they will continue to reduce vehicle mass to meet more stringent standards, and therefore, this expectation is incorporated into the modeling analysis supporting the standards. Safety trade-offs associated with mass-reduction have occurred in the past,

¹⁹¹⁹ EDF, Appendix A, NHTSA-2018-0067-12108, at 7-9.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

particularly before CAFE standards were attribute-based; past safety trade-offs may have occurred because manufacturers chose at the time, in response to CAFE standards, to build smaller and lighter vehicles. In cases where fuel economy improvements were achieved through reductions in vehicle size and mass, the smaller, lighter vehicles did not fare as well in crashes as larger, heavier vehicles, on average. Although the agencies now use attribute-based standards, in part to reduce or eliminate the incentive to downsize vehicles to comply with CAFE and CO₂ standards,¹⁹²⁰ the agencies must be mindful of the possibility of related safety trade-offs.

Historically, as shown in FARS data analyzed by the agencies, mass reduction concentrated among the heaviest vehicles (chiefly, the largest LTVs, CUVs and minivans) is estimated to reduce overall fatalities, while mass reduction concentrated among the lightest vehicles (chiefly, smaller passenger cars) is estimated to increase overall fatalities. Mass reduction in heavier vehicles is more beneficial to the occupants of lighter vehicles than it is harmful to the occupants of the heavier vehicles. Mass reduction in lighter vehicles is more harmful to the occupants of lighter vehicles than it is beneficial to the occupants of the heavier vehicles. In response to questions of whether designs and materials of more recent model year vehicles may have weakened the historical statistical relationships between mass, size, and safety, we updated our public database for statistical analysis consisting of crash data. The analysis considered the full range of real-world crash types.

The methodology used for the statistical analysis of historical crash data has evolved over many years. The methodology used for the NPRM and unchanged for the final rule reflects learnings and refinements from: NHTSA studies in 2003, 2010, 2011, 2012, and 2016; independent peer review of 23 studies by the University of Michigan Transportation Research Institute;¹⁹²¹ two public workshops hosted by NHTSA;¹⁹²² interagency collaboration among NHTSA, DOE and EPA; and comments to CAFE and CO₂ rulemakings in 2010, 2012, the 2016 Draft TAR, and the 2018 NPRM. As explained in greater detail below, the methodology used for the statistical analysis of historical crash data for the NPRM and final rule is the best and most up to date available.

¹⁹²⁰ CAFE and CO₂ standards are “footprint-based,” with footprint being defined as a measure of a vehicle’s size, roughly equal to the wheelbase times the average of the front and rear track widths. Footprint-based standards create a disincentive for manufacturers to produce smaller-footprint vehicles. This is because, as footprint decreases, the corresponding fuel economy/CO₂ emission target becomes more stringent. We also believe that the shape of the footprint curves themselves is such that the curves should neither encourage manufacturers to increase nor decrease the footprint of their fleets.

Available at <http://www.umtri.umich.edu/our-results/publications/independent-review-statistical-analyses-relationship-between-vehicle-curb>.

¹⁹²² The workshops were held on February 25, 2011 and May 13-14, 2013. Video, transcripts, and presentations are available on the NHTSA website (recommended search terms include “workshop”, “mass”, “safety”, and the dates of the workshops).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Additionally, to assess whether future vehicle designs may impact the relationship of vehicle mass reduction on safety, NHTSA sponsored a fleet crash simulation study using future mass reduction vehicle design concepts (see *Fleet Simulation Study* below). The results of the simulation research showed that future mass reduction techniques continue to exhibit impacts on safety and were consistent with the statistical analysis of FARS crash data. The agencies considered the findings of the study and concluded it was reasonable and appropriate to continue to consider the impact of mass reduction on safety for future vehicles because the data indicate the relationship between mass and safety will continue in the future.

For the rulemaking analysis, the CAFE model tracks the amount of mass reduction applied to each vehicle model, and then applies estimated changes in societal fatality risk per 100 pounds of mass reduction determined through the statistical analysis of FARS crash data. This process allows the CAFE model to tally changes in fatalities attributed to mass reduction across all of the analyzed future model years. In turn, the CAFE model is able to provide an overall impact of the final standards and alternatives on fatalities attributed to mass reduction.

A number of comments were received on technical aspects of the mass-safety analysis in the NPRM. The agencies carefully considered all comments. Where warranted, the agencies conducted additional analyses to determine whether commenters' suggestions would improve the analysis. The agencies found that the methodology employed by the proposal, which was developed over many years, subject to extensive review and feedback, remains the most rigorous methodology. The agencies found the alternative approaches raised in comments would provide less likely estimates, were statistically problematic, or, in some cases, advocated discarding or ignoring the most likely estimates altogether. The agencies' assessments of comments are discussed in detail in the subsections below.

Overall, consistent with prior analyses, the data show that mass reduction concentrated in heavier vehicles is generally beneficial to overall safety, and mass reduction concentrated in lighter vehicles is harmful.

(1) *Crash Data*

The agencies use real-world crash data as the basis for projecting the future safety implications for regulatory changes. To support the 2012 rulemaking, NHTSA created a common, updated database for statistical analysis consisting of crash data. The initial iteration contained crash data for model years 2000-2007 vehicles in calendar years 2002-2008. NHTSA made the preliminary version of the new database, which was the basis for NHTSA's 2011 preliminary report (*hereinafter* 2011 Kahane report),¹⁹²³ available to the public in May 2011, and an updated version in April 2012 (used in NHTSA's 2012 final report, *hereinafter* 2012 Kahane

¹⁹²³ Kahane, C. J. *Relationships Between Fatality Risk, Mass, and Footprint in Model Year 2000-2007 Passenger Cars and LTVs – Final Report*, National Highway Traffic Safety Administration (Aug. 2012). Available at <https://crashstats.nhtsa.dot.gov/Api/Public/ViewPublication/811665>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

report),¹⁹²⁴ enabling other researchers to analyze the same data and, hopefully, minimize discrepancies in results caused by reporting inconsistencies across databases.¹⁹²⁵ NHTSA updated the crash and exposure databases for the 2016 Draft TAR analysis.

For the proposed rule and unchanged for today's final rule, the crash and exposure databases were updated again. The databases are the most up-to-date possible (MY 2004-2011 vehicles in CY 2006-2012), given the processing time for crash data and the need for enough crash cases to permit statistically meaningful analyses. As in previous analyses, NHTSA has made the new databases available to the public on its website.¹⁹²⁶

(2) Methodology

The relationship between a vehicle's mass, size, and fatality risk is complex, and it varies in different types of crashes. We have been examining this relationship for more than two decades. The basic analytical method used to analyze the impacts of weight reduction on safety for the proposal, and unchanged for this final rulemaking, is the same as in 2016 Puckett and Kindelberger report.¹⁹²⁷ NHTSA released the 2016 Puckett and Kindelberger report as a preliminary report on the relationship between fatality risk, mass, and footprint in June 2016 in advance of the Draft TAR. The 2016 Puckett and Kindelberger report covered the same scope as previous NHTSA reports,¹⁹²⁸ offering a detailed description of the crash and exposure databases, modeling approach, and analytical results on relationships among vehicle size, mass, and fatalities that informed the Draft TAR. The modeling approach described in the 2016 Puckett and Kindelberger report was developed with the collaborative input of NHTSA, EPA and DOE, and subject to extensive public review, scrutiny in two NHTSA-sponsored workshops, and a thorough peer review that compared it with the methodologies used in other studies.¹⁹²⁹

In computing the impact of changes in mass on safety, the agencies are faced with competing challenges. Research has consistently shown that mass reduction affects "lighter" and

¹⁹²⁸ The 2016 Puckett and Kindelberger report is an extension of 2011 Kahane report and 2012 Kahane report.

¹⁹²⁹ Previous reports from which the 2016 Puckett and Kindelberger report was derived from, were also subject to extensive peer reviews. Farmer, Green, and Lie, who reviewed the 2010 Kahane report, also peer-reviewed the 2011 Kahane report. In preparing his 2012 report (along with the 2016 Puckett and Kindelberger report and Draft TAR), Kahane also took into account Wenzel's assessment of the preliminary report and its peer reviews, DRI's analyses published early in 2012, and public comments such as the International Council on Clean Transportation's comments submitted on NHTSA and EPA's 2010 notice of joint rulemaking. These comments prompted supplementary analyses, especially sensitivity tests, discussed at the end of this section.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

“heavier” vehicles differently across crash types. The 2016 Puckett and Kindelberger report found mass reduction concentrated amongst the heaviest vehicles is likely to have a beneficial effect on overall societal fatalities, while mass reduction concentrated among the lightest vehicles is likely to have a detrimental effect on fatalities.¹⁹³⁰ To accurately capture the differing effect on lighter and heavier vehicles, the agencies must split vehicles into lighter and heavier vehicle classifications in the analysis.¹⁹³¹ However, this poses a challenge of creating statistically-meaningful results. There is limited relevant crash data to use for the analysis. Each partition of the data reduces the number of observations per vehicle classification and crash type, and thus reduces the statistical robustness of the results. The methodology employed by the agencies was designed to balance these competing forces as an optimal trade-off to accurately capture the impact of mass-reduction across vehicle curb weights and crash types while preserving the potential to identify robust estimates.

For the proposal and the final rule, the agencies employed the modeling technique developed in the 2016 Puckett and Kindelberger report to analyze the updated crash and exposure data by examining the cross sections of the societal fatality rate per billion vehicle miles of travel (VMT) by mass and footprint, while controlling for driver age, gender, and other factors, in separate logistic regressions for five vehicle groups and nine crash types. “Societal” fatality rates include fatalities to occupants of all the vehicles involved in the collisions, plus any pedestrians, cyclists, or occupants of other conveyances (e.g., motorcyclists). The agencies utilize the relationships between weight and safety from this analysis, expressed as percentage increases in fatalities per 100-pound weight reduction, to examine the weight impacts applied in this CAFE analysis. The effects of mass reduction on safety were estimated relative to (incremental to) the regulatory baseline (augural standards) in the CAFE analysis, across all vehicles for MYs 2018 and beyond.

As in the 2012 Kahane report, 2016 Puckett and Kindelberger report, and the Draft TAR, the vehicles are grouped into three classes: passenger cars (including both two-door and four-door cars); CUVs and minivans; and truck-based LTVs. The curb weight of passenger cars is formulated, as in the 2012 Kahane report, 2016 Puckett and Kindelberger report, and Draft TAR, as a two-piece linear variable to estimate one effect of mass reduction in the lighter cars and another effect in the heavier cars. The boundary between “lighter” and “heavier” cars is 3,201 pounds (which is the median mass of MY 2004-2011 cars in fatal crashes in CY 2006-2012, up from 3,106 pounds for MY 2000-2007 cars in CY 2002-2008 in the 2012 NHTSA safety database, and up from 3,197 pounds for MY 2003-2010 cars in CY 2005-2011 in the 2016 NHTSA safety database). Likewise, for truck-based LTVs, curb weight is a two-piece linear variable with the boundary at 5,014 pounds (again, the MY 2004-2011 median, higher than the median of 4,594 pounds for MY 2000-2007 LTVs in CY 2002-2008 and the median of 4,947

¹⁹³⁰ The findings of the 2016 Puckett and Kindelberger report are consistent with the results of the 2012 Kahane report and Draft TAR.

¹⁹³¹ If lighter and heavier vehicles are left undistinguished, the agencies analysis would be restricted to identifying a single effect of mass reduction for passenger cars and a single effect of mass reduction for truck-based LTVs. As discussed below, distinct effects have been estimated historically for lighter versus heavier vehicles for cars and LTVs, confirming the validity of distinguishing by curb weight where feasible.

pounds for MY 2003-2010 LTVs in CY 2005-2011). CUVs and minivans are grouped together in a single group covering all curb weights of those vehicles; as a result, curb weight is formulated as a simple linear variable for CUVs and minivans. Historically, CUVs and minivans have accounted for a relatively small share of new-vehicle sales over the range of the data, resulting in less crash data available than for cars or truck-based LTVs. In sum, vehicles are distributed into five groups by class and curb weights: passenger cars < 3,201 pounds; passenger cars 3,201 pounds or greater; truck-based LTVs < 5,014 pounds; truck-based LTVs 5,014 pounds or greater; and all CUVs and minivans.

There are nine types of crashes specified in the analysis for each vehicle group: three types of single-vehicle crashes, five types of two-vehicle crashes; and one classification of all other crashes. Single-vehicle crashes include first-event rollovers, collisions with fixed objects, and collisions with pedestrians, bicycles and motorcycles. Two-vehicle crashes include collisions with: heavy-duty vehicles; cars, CUVs, or minivans < 3,187 pounds (the median curb weight of other, non-case, cars, CUVs and minivans in fatal crashes in the database); cars, CUVs, or minivans \geq 3,187 pounds; truck-based LTVs < 4,360 pounds (the median curb weight of other truck-based LTVs in fatal crashes in the database); and truck-based LTVs \geq 4,360 pounds. Grouping partner-vehicle CUVs and minivans with cars rather than LTVs is more appropriate because their front-end profile and rigidity more closely resemble a car than a typical truck-based LTV. An additional crash type includes all other fatal crash types (e.g., collisions involving more than two vehicles, animals, or trains). Splitting the vehicles from this crash type involved in crashes involving two light-duty vehicles into a lighter and a heavier group permits more accurate analyses of the mass effect in collisions of two vehicles.

For a given vehicle class and weight range (if applicable), regression coefficients for mass (while holding footprint constant) in the nine types of crashes are averaged, weighted by the number of baseline fatalities that would have occurred for the subgroup MY 2008-2011 vehicles in CY 2008-2012 if these vehicles had all been equipped with electronic stability control (ESC). The adjustment for ESC, a feature of the analysis added in 2012, takes into account results will be used to analyze effects of mass reduction in future vehicles, which will all be ESC-equipped, as required by NHTSA's safety regulations.

The agencies received multiple comments on how they distribute vehicles into classifications. IPI, quoting a study by Tom Wenzel, commented that sorting vehicles into footprint deciles shows positive impacts from mass reduction for the majority of the footprint deciles.¹⁹³² CARB commented that the agencies should have used the curb weight of all vehicles to calculate the thresholds for "lighter" and "heavier" vehicle types rather than just the curb weights of vehicles involved in fatal crashes.¹⁹³³ CARB also commented that pickup trucks and SUVs that are not subject to CAFE regulation (i.e., Class 2b and Class 3 vehicles, such as $\frac{3}{4}$ -ton

¹⁹³² IPI, Detailed Comments, Docket No. NHTSA-2018-0067-12213, at 127 (quoting Tom Wenzel, *Assessment of NHTSA's Report "Relationships Between Fatality Risk, Mass, and Footprint in Model Year 2004-2011 Passenger Cars and LTVs,"* (LBNL Phase 1, 2018). Available at <https://escholarship.org/uc/item/4726g6jq>.

¹⁹³³ CARB, Detailed Comments, Docket No. NHTSA-2018-0067-11873, at 276.

and one-ton pick-up trucks, vans and related SUVs) should not be included in the assessment of the impact of mass on safety and doing so raises the median weight of trucks.¹⁹³⁴ CARB also commented that the median weights are static values representing the historical fleet, but the median weights and proportions of crash types involving given vehicle weight categories should change with median weight of the fleet modeled by the CAFE model.¹⁹³⁵ Commenters generally believed that the agencies' approach "results in inappropriate apportioning of cars and trucks into the corresponding lighter or heavier bins," which in turn causes the agencies to overestimate the fatalities associated with mass reduction.¹⁹³⁶

Dividing vehicles into footprint deciles and excluding Class 2b and 3 vehicles pose sample size and data coverage issues. If vehicles were grouped into footprint deciles, the sample sizes in each decile would be approximately one-fifth as large as the corresponding sample sizes in each of the agencies' four passenger car and LTV vehicle classes (and one-tenth as large as the sample size for CUVs and minivans). Smaller parameter estimates require correspondingly smaller standard errors (i.e., relatively precise estimates) to achieve statistical significance, but splitting the limited data into deciles yields larger standard errors, restricting the ability to identify statistically-significant estimates. Likewise, by extending the footprint-curb weight-fatality data to include Class 2b and 3 trucks that are functionally and structurally similar to corresponding ½-ton models that are subject to CAFE regulation,¹⁹³⁷ the sample size and ranges of curb weights and footprint are improved. Sample size is a challenge for estimating relationships between curb weight and fatality risk for individual crash types in the main analysis; dividing the sample further or removing observations makes it exceedingly difficult to identify meaningful estimates and the relationships that are present in the data.

¹⁹³⁴ Tom Wenzel of Lawrence Berkeley National Laboratories, Comment, EPA-HQ-OAR-2018-0283-4118, at 1; *see also* CARB, Detailed Comments, Docket No. NHTSA-2018-0067-11873, at 259.

¹⁹³⁵ CARB, Detailed Comments, Docket No. NHTSA-2018-0067-11873, at 260.

¹⁹³⁶ CARB, Detailed Comments, Docket No. NHTSA-2018-0067-11873, at 276.

¹⁹³⁷ Class 2b and 3 pickup trucks, vans and SUVs have physical characteristics and usage profiles that are substantially similar to their Class 2a counterparts. For example, the Class 2a version of the Ford F-150 has similar physical characteristics to and has a similar usage profile to the Class 2b Ford F150. Same for the Class 2a Ford F150 relative to the Class 2b and 3 Ford F250, and for the GMC Yukon relative to the Yukon XL. The Class 2b and 3 pickup trucks in the sample generally have gross vehicle weight ratings of 10,000 pounds or less, and thus are subject to the same Federal motor vehicle safety standards as their light-duty counterparts. Likewise, these vehicles generally have similar physical dimensions (e.g., ground clearance, width) as related light-duty vehicles. Key differentiating factors among these vehicles are height, payload, and towing capacity. There are likely to be unobserved differences in how these vehicles are driven relative to light-duty alternatives; however, the crash data include a census of fatal crashes involving case vehicles and the Class 2b and 3 vehicles included in the analysis, in turn representing the relative risk of differences in curb weight in crashes involving Class 2b and 3 vehicles. Despite being regulated by different fuel economy and emissions regulations as they become heavier (i.e., once a given model crosses a mass threshold changes classes), the vehicles may continue to be used in similar ways over time; in turn, the safety implications of the presence of these vehicles may continue to be similar. In contrast, other types of heavy-duty vehicles, such as box trucks, buses, refuse trucks, fire trucks, and other heavy-duty commercial vehicles are substantially different from light duty vehicles in their physical characteristics and usage profiles, and it would not be appropriate to include them in the statistical analysis to determine the impact of mass on crash fatalities.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Compounding the issue is the fact the analysis focuses on societal fatality risk (i.e., all fatalities, including crash partners and people outside of vehicles, such as pedestrians, cyclists, and motorcyclists) rather than merely in-vehicle fatality risk, which yields estimates that are smaller in magnitude (and thus more difficult to identify meaningful differences from zero) than estimates representing changes in in-vehicle fatality risk. That is, compared to an analysis of in-vehicle fatality risk (which would tend to yield relatively large estimated effects of mass reduction), the focus on societal fatalities tends to yield relatively small (net) effects of mass reduction on fatality risk.

Including Class 2b and 3 vehicles in the analysis to determine the relationship of vehicle mass on safety has the added benefit of improving correlation constraints. Notably, curb weight increases faster than footprint for large light trucks and Class 2b and 3 pickup trucks and SUVs, in part because the widths of vehicles are constrained more tightly (i.e., due to lane widths) than their curb weights. Including data from Class 2b and 3 pick-up truck and SUV fatal crashes provides data over a wider range of vehicle weights, which improves the ability to estimate the mass-crash fatality relationship. The agencies believe the decision of whether to include Class 2b and 3 vehicles in the analysis should be made based on whether the additional data improves the estimate of the safety impact of mass reduction in light trucks, and that the fatality data should not be simplistically excluded because the vehicles are not regulated under the CAFE and CO₂ emissions programs. Ultimately, the agencies find that: (1) the fundamental objective is to capture the strongest, meaningful signal regarding societal fatality risk as a function of the mass of light trucks; (2) that incorporating information on fatal incidents involving Class 2b and 3 trucks improves the quality of the signal the agencies can capture, and (3) including the vehicles provides the best estimate of the impacts of mass on societal fatalities.

In assessing whether to calculate the median curb weight threshold from all vehicles involved in accidents or on the road, the agencies weighed changing the process used to establish the thresholds and the potential impact on the robustness of the statistical analysis. From a statistical perspective, using thresholds that allocate a similar number of fatal crash cases to both the lower vehicle weight group and the higher vehicle weight group for a given vehicle type will minimize the average standard errors of estimates for both groups, which provides the best estimates for each group. Because reducing average standard errors strengthens the statistical analysis, the agencies conclude using only the curb weight of vehicles involved in fatal crashes to calculate the median curb weight threshold produces the best estimate. This conclusion is the same that was reached previously when considering the same issue for the 2011 Kahane, 2012 Kahane, and 2016 Puckett and Kindelberger analyses.

On a related note, the regression models are estimated based on with respect to the total number of fatalities associated within each vehicle weight group classification (referred to as vehicle group below, for brevity). Shifting the threshold would change the estimated incremental impact of changes in curb weight in each vehicle group, but the net effects would offset each other across vehicle groups, resulting in the same overall estimated effect of changes in vehicle mass on societal fatality risk. For example, if one restricted the “lightest” group for a vehicle type to include only the bottom ten percentiles of vehicle weight, one would expect to identify a very strong detrimental effect (or weakest beneficial effect) of mass reduction for that group. However, the estimated effect of mass reduction in that group has minimal implications

for the fleet (i.e., because there are fewer vehicles in the group), and the corresponding estimated effect of mass reduction for other groups would also mute the impact (i.e., because there are many vehicles in the group that vary in mass to a much larger degree than in the “lighter” group). Ultimately, the mean effect of mass reduction across the lighter and heavier groups would be the same as when using the median as the threshold (or at least, similar, subject to limitations in statistical optimization), but with a different point of reference when comparing the groups. Thus, the agencies believe the selection of curb weight threshold has a minimal impact on the estimated effects of mass reduction across all vehicle types.

Full consideration of CARB’s comment on mass thresholds, and whether they should change as the median weight of the fleet modeled by the CAFE model changes, requires a deeper look at each of the crash types considered in the analysis. That is, the point estimates presented in [Table II-95](#)~~Table 1-1~~ represent weighted averages across nine separate, mutually-exclusive and exhaustive crash models (analyzed separately for cars, LTVs, and CUVs and minivans). For example, an individual model for first-event rollovers yields estimates of the percentage change in societal fatality risk per 100-pound mass reduction for lighter and heavier (or, in the case of CUVs and minivans, all) vehicles in the target vehicle class. The final, overall point estimate for a given vehicle type is found by: (1) multiplying the estimate associated with an individual crash type by the estimated share of societal fatalities involving the vehicle class (adjusting for two-vehicle collisions that span vehicle classes to avoid double-counting); and (2) summing the values estimated in (1) across all crash types. In its comments, CARB noted that if the distribution of vehicles in terms of curb weight changes through lightweighting, the shares of (fatal) two-vehicle crashes involving a given pair of vehicles as defined by weight class (e.g., car below a given threshold colliding with a LTV above a given threshold) would change. In turn, the appropriate weighting across the crash types modeled in the analysis would likewise be different (involving an increasing share of vehicles below a given curb weight threshold). Due to these potential limitations, CARB questioned the stability of the summary point estimates relative to changes in the shares of fatalities within each crash type in the analysis.¹⁹³⁸

To evaluate CARB’s concerns regarding future crash mixes and definitions of vehicle weight classes, the agencies performed an exploratory analysis examining the scope and impacts of potential model changes. In doing so, the agencies examined the degree of change in the median vehicle fleet weight in the NPRM analysis relative to the fixed mass threshold values, and also how sensitive the curb weight safety point estimates are to assumptions about the distribution of curb weights in future vehicle fleets. The agencies also considered the feasibility of changing the shares of fatalities by crash type as a function of forthcoming or developing vehicle safety technologies. This information would help inform adjustments to fatality rate impacts for each vehicle type, because the likelihood of observing individual fatal crash types could change in different ways across vehicle types in the analysis as the vehicle mix changes. However, the agencies identified no studies on the effectiveness of forthcoming or developing vehicle safety technologies that could inform projections of shares of fatalities across crash types, nor did the commenters reference any such studies. Likewise, commenters provided no

¹⁹³⁸ CARB, Detailed Comments, Docket No. NHTSA-2018-0067-11873, at 278-79.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

data that would enable projections of these factors. Thus, for a given vehicle mix, the agencies have no information available to justify changing the shares of fatalities across crash types over time. Therefore, the agencies decided to keep the distribution of fatality shares constant for: first-event rollovers; fixed-object collisions; collisions with pedestrians, bicyclists, and motorcycles; collisions with heavy vehicles; collisions with one other light-duty vehicle (i.e., a constant share across the sum of these crashes, but not constant for any given type of crash partner); and all other crashes.

The agencies had sufficient information to evaluate the effects of changes in the fatal crash mix for cases involving two light-duty vehicles. The agencies agreed that it was internally consistent to adjust fatality shares by crash type proportionally to the distribution of vehicle types and curb weight classes for a given focal MY. An important technical question associated with this approach is the level of disaggregation. The agencies considered an alternative in which the agencies would estimate and apply unique curb weight point estimates for each calendar year in the analysis for each regulatory alternative. This alternative would account for changes in the distribution of crash types associated with changes in both vehicle type shares (i.e., shifts from passenger cars to CUVs and LTVs) and vehicle mass shares (i.e., shifts from vehicles above the curb weight thresholds to vehicles below the thresholds). As in the status quo analysis of curb weight and fatality risk, the resulting point estimates would be weighted averages across the individual crash type models as presented in the NPRM, but re-weighted to reflect projected changes to the fleet.

The agencies investigated this alternative and identified several concerns. A key functional constraint is that the curb weight safety point estimates are applied in the CAFE model as a lump-sum, lifetime effect to a given vehicle. This characteristic of the model limits the ability to apply calendar-year-specific effects of changes in curb weight and vehicle type distributions when evaluating safety impacts of changes in curb weights. The safety point estimates also represent net effects of changes in curb weights over the lifetime of a given vehicle in the CAFE model; any changes in the calculation of safety point estimates would need to preserve this characteristic. More broadly, the vehicle fleet is not static over a vehicle's lifetime (i.e., the distributions of curb weight and vehicle type change each year), so the effective probabilities of each crash type over a given vehicle's lifetime are a function of many calendar-year-level curb weight and vehicle type distributions. To capture any effects of changes in vehicle mass distributions over time within the current CAFE model structure, the agencies would need to enact a method that: (1) identifies defensible changes in fatality risk associated with vehicle mass as the distribution of vehicle mass changes (e.g., accounting for changes in the likelihood of observing particular fatal crash types that reflect projected changes in the distribution of vehicle types and curb weights across vehicles); and (2) allocates calendar-year-specific impacts of curb weight on fatality risk to each vehicle in the fleet across the analysis horizon. Identifying how best to achieve this would be complex, and would require the development of an alternative analytical approach that would be outside the scope of this rulemaking.

With these concerns in mind, the agencies explored an alternative approach to test the sensitivity of the safety point estimates to distributions of vehicles by curb weight and vehicle type. The starting point for the alternative approach is maintaining the understanding that the

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

nine crash type models that are present in the curb weight safety analysis represent the best statistical alternatives for evaluating the crash data in the database (i.e., optimal statistical precision conditional on the coverage of the data). Furthermore, the nine crash type models are defined in terms of physical relationships (i.e., crashes involving vehicles of particular curb weight ranges and vehicle types) that are invariant to changes in the distributions of vehicles for those same characteristics. That is, the estimated changes in societal fatality risk as curb weights change for a focal vehicle (i.e., of a particular type and weight range) that is involved in a particular type of crash apply equally to any scenario involving such vehicle, regardless of changes in the probability of observing such a scenario. For example, we would expect the societal fatality risk for a crash involving a passenger car lighter than 3,201 pounds colliding with a LTV heavier than 4,360 pounds to be the same regardless of how many such collisions take place. Thus, we would expect the net effect of a given change in curb weight for a given vehicle type in a given crash type to scale proportionally with the probability of such crashes occurring. Put simply, if there are half as many potential crash partners of a given type in a future year compared to a base year, we would expect a given curb weight reduction to have half as large of a net effect on fatalities in the future year relative to the base year. In the extreme, curb weight changes would have no net effect on fatalities at all for a given crash type if such crashes had a zero percent probability of occurring (i.e., if there are no potential crash partner vehicles).

Based on this maintained hypothesis, the agencies examined test curb weight safety point estimates under alternative scenarios, in which fatality shares by crash type were proportional to the distribution of vehicle types and curb weight classes across a range of outcomes reflecting different model years and policy alternatives represented in the NPRM. The sensitivities of the safety point estimates to changes in the distributions of vehicle curb weights and vehicle types were tested by adjusting fatality shares across the relevant crash types in the analysis (i.e., involving two light-duty vehicles) in a manner consistent with potential changes in the vehicle fleet, while holding the outputs of the individual crash type models the same as in the NPRM.

For example, compare the safety point estimate for LTVs lighter than 5,014 pounds in the NPRM with an alternative point estimate for an extreme hypothetical future year where 80 percent of the LTV fleet is lighter than the median curb weight for crash partners (4,360 pounds):

Table II-95+68 - Calculation of Example Alternative Safety Point Estimate (LTVs Lighter than 5,014 Pounds)

Total	1.00	1.00	NPRM: 0.31 Example: 0.28	5.5	4.9

The estimated net societal effect of a 100-pound mass reduction is equal to: (1) the sum of the estimated net effects across all crash types, divided by (2) the baseline estimate of annual fatalities involving the vehicle class (adjusted to avoid double-counting) for the most recent four MYs in the database (MYs 2008-2011), or 1,782 fatalities per year. In the NPRM, the estimated net societal effect of a 100-pound mass reduction for lighter LTVs was a 5.5 fatality increase, or a 0.31 percent increase relative to a baseline of 1,782 fatalities. Changing the share of crash fatalities involving heavier LTVs to be consistent with a fleet with only 20 percent of LTVs above the curb weight threshold yields: (1) an increase in incremental fatalities in crashes involving lighter LTVs (from 0.5 fatality to 0.7 fatality); and (2) a decrease in incremental fatalities in crashes involving heavier LTVs (from 1.5 fatalities to 0.7 fatality); for a total net increment of 4.9 fatalities compared to the NPRM's estimate of 5.5 fatalities. Thus, we estimate that, in a future year where the fleet differs from the baseline by having an extreme case of 80 percent of LTVs below the crash-partner curb weight threshold, the net societal effect of a 100-pound mass reduction in LTVs lighter than 5,014 pounds would be 4.9 divided by 1,782, or 0.28 percent, versus 0.31 percent in the baseline.

This simple example confirms that the estimates do indeed change as the distribution of curb weights changes. In this case, the change is intuitive: As the LTV fleet becomes lighter, mass reduction among LTVs below 5,014 pounds becomes less detrimental to society. However, the incremental effect is estimated to be quite small: Shifting from an even mix of LTVs above and below the threshold to an extreme 20%/80% split only changes the estimated net societal effect by 0.03 percent in absolute terms. Thus, the model results for lighter LTVs appear relatively insensitive to the LTV curb weight distribution. Indeed, in the limit, where all LTVs are below the crash-partner curb weight threshold (and thus there are no fatality impacts for crashes involving heavier LTVs), the estimated net societal effect of a 100-pound mass reduction for LTVs below 5,014 pounds (i.e., *all* LTVs in this case) is 0.25 percent, a difference of 0.06 percent in absolute terms compared to the baseline. This result is driven by the dominating effects of crash types involving either: (1) no crash partner (e.g., first-event rollovers); (2) one crash partner from a group not associated with a given change in a curb weight distribution (e.g., heavy vehicles, bicyclists, passenger cars); or (3) multiple crash partners (an element of "all other crashes"). That is, even extreme changes in the distribution of curb weights for a given vehicle type will not change the role that vehicle mass plays in crashes for a focal vehicle when that vehicle does not collide with another vehicle from the distribution in question. In the above example involving lighter LTVs, 90 percent of fatalities involve incidents that do not include a single LTV crash partner, and 66 percent of fatalities involve incidents that do not include a single light-duty crash partner.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Continuing with this example scenario, the point estimate for LTVs heavier than 5,014 pounds becomes larger in magnitude (i.e., more societally beneficial mass reduction) to a similar degree as the reduction in magnitude for lighter LTVs when moving to an extreme 20%/80% split of crash partner LTVs above (versus below in the case above) the curb weight threshold:

Table II-96469 - Calculation of Example Alternative Safety Point Estimate (LTVs 5,014 Pounds or Heavier)

Crash Type	Share of Fatalities		Change in Fatality Risk per 100-Pound Mass Reduction for Crash Type (%)	Change in Fatalities per 100-Pound Mass Reduction for Crash Type (Baseline = 3,304)	
	NPRM	Example		NPRM	Example
First-Event Rollover	0.02	0.02	0.76	0.6	0.6
Hit Fixed Object	0.09	0.09	0.99	3.1	3.1
Hit Pedestrian/Bicycle/Motorcycle	0.19	0.19	0.02	0.1	0.1
Hit Heavy Vehicle	0.06	0.06	0.79	1.6	1.6
Hit Car/CUV/Minivan < 3,187 Lbs.	0.14	0.14	-2.56	-12.0	-12.0
Hit Car/CUV/Minivan 3,187+ Lbs.	0.13	0.13	-0.36	-1.5	-1.5
Hit Truck-Based LTV < 4,360 Lbs.	0.07	0.10	-1.81	-4.0	-6.1
Hit Truck-Based LTV 4,360+ Lbs.	0.06	0.03	0.81	1.6	0.7
All Other	0.24	0.24	-1.20	-9.5	-9.5
Total	1.00	1.00	NPRM: -0.61 Example: -0.69	-20.0	-22.9

In the NPRM and this analysis, the estimated net societal effect of a 100-pound mass reduction for lighter LTVs was a 20.0 fatality decrease, or a 0.61 percent decrease relative to a baseline of 3,304 fatalities. Changing the share of crash fatalities involving heavier LTVs to be consistent with a fleet with only 20 percent of LTVs above the curb weight threshold yields: (1) a larger reduction in fatalities in crashes involving lighter LTVs per 100-pound mass reduction (from 4.0 fatalities to 6.1 fatalities); and (2) a decrease in incremental fatalities in crashes involving heavier LTVs (from 1.6 fatalities to 0.7 fatality); for a total net change of -22.9 fatalities compared to a baseline of -20.0 fatalities. Thus, we estimate that, in a future year where the fleet differs from the baseline by having 80 percent of LTVs below the crash-partner curb weight threshold, the net societal effect of a 100-pound mass reduction in LTVs 5,014 pounds or heavier would be -22.9 divided by 3,304, or -0.69 percent, versus -0.61 percent in the baseline. Consistent with the test results for lighter LTVs, the model results for heavier LTVs appear relatively insensitive to the LTV curb weight distribution. In the limit, where all LTVs (except for one remaining heavier LTV in consideration) are below the crash-partner curb weight threshold (and thus there are no effective fatality impacts for crashes involving heavier LTVs), the estimated net societal effect of a 100-pound mass reduction for the remaining LTV above 5,014 pounds is -0.76 percent, a difference of 0.15 percent in absolute terms compared to the baseline.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Expanding the analysis to account for changes in the relative sales shares of each vehicle type dampens the net effects further. As the fleet share of passenger cars decreases, the net effects of mass reduction among LTVs become less societally beneficial. That is, as there are fewer relatively vulnerable passenger cars in the fleet, there become fewer opportunities to reduce fatalities in collisions between LTVs and passenger cars through mass reduction. In some scenarios considered in the exploratory analysis, the effects of sales shifts from passenger cars to LTVs at least fully offset the estimated improvements in net fatalities associated with mass reduction summarized above as the LTV fleet becomes lighter.

Ultimately, the exploratory analysis using extreme example cases confirmed that the baseline safety point estimates are very reasonable for the feasible ranges of mixes of vehicle types and curb weights across the model years in the CAFE model analysis. The sensitivities of the point estimates are relatively low across relative shares of lighter versus heavier LTVs (especially relative to the uncertainty in the baseline estimates), and similarly low and offsetting across decreasing fleet shares for passenger cars. Because shifts in mass in the rulemaking analysis would have insignificant impacts on the safety estimated values and therefore rulemaking decision making, the agencies conclude no changes are warranted for this final rule analysis.

(3) Mass Safety Results

Table II-97Table I-3 presents the estimated percent increase in U.S. societal fatality risk per 10 billion VMT for each 100-pound reduction in vehicle mass, while holding footprint constant, for each of the five vehicle classes:

Table II-97470 - Fatality Increase (Percent) per 100-Pound Mass Reduction While Holding Footprint Constant: MY 2004-2011, CY 2006-2012

	Central Estimate	95% Confidence Bounds
Cars < 3,201 pounds	1.20	-.35 to +2.75
Cars > 3,201 pounds	0.42	-.67 to +1.50
CUVs and minivans	-0.25	-1.55 to +1.04
Truck-based LTVs < 5,014 pounds	0.31	-.51 to +1.13
Truck-based LTVs > 5,014 pounds	-0.61	-1.46 to +.25

Techniques developed in the 2011 (preliminary) and 2012 (final) Kahane reports have been retained to test statistical significance and to estimate 95-percent confidence bounds (sampling error) for mass effects and to estimate the combined annual effect of removing 100 pounds of mass from every vehicle (or of removing different amounts of mass from the various classes of vehicles), while holding footprint constant.

None of the estimated effects have 95-percent confidence bounds that exclude zero, and thus are not statistically significant at the 95-percent confidence level. The NPRM reported that two estimated effects are statistically significant at the 85-percent level. Societal fatality risk is estimated to: (1) increase by 1.2 percent if mass is reduced by 100 pounds in the lighter cars; and

(2) decrease by 0.61 percent if mass is reduced by 100 pounds in the heavier truck-based LTVs. The estimated increases in societal fatality risk for mass reduction in the heavier cars and the lighter truck-based LTVs, and the estimated decrease in societal fatality risk for mass reduction in CUVs and minivans are not significant, even at the 85-percent confidence level. Although 85-percent statistical significance is not a traditional metric of meaningful differences to zero, this result confirms that the estimated effects for vehicles with curb weights most dissimilar to the median vehicle are the most likely to be significantly different to zero.

The agencies judge the central value estimates are the best and most up-to-date estimates available; the estimates offer a stronger statistical representation of relationships among vehicle curb weight, footprint and fatality risk than an assumption of no correlation whatsoever. The agencies appropriately present the statistical uncertainty. For example, the central values for the highest vehicle weight group (LTVs 5,014 pounds or heavier) and the lowest vehicle weight group (passenger cars lighter than 3,201 pounds) (which, based on fundamental physics, are expected to have the greatest impact of mass reduction on safety) are economically significant¹⁹³⁹, and are in line with the prior analyses used in past NHTSA CAFE and EPA CO₂ rulemakings. As shown in [Table II-98](#)~~Table I-4~~, the estimated coefficients have trended to lower numerical values in successive studies, but remain positive for lighter cars and negative for heavier LTVs. The 85-percent confidence level was reported only to show the scope of uncertainty at the first rounded (to five percent) threshold where the coefficient estimates were significantly different to zero for the two vehicle groups at the extremes of the curb weight distribution. No preference was suggested for an 85-percent confidence bound. Rather, the agencies found value in reporting confidence intervals for all five coefficients at the threshold where the estimates for the two extremes of the curb weight distribution were significantly different to zero. The agencies determined it was better to include the estimates, despite the slightly lower confidence level, than knowingly omitting economically significant results.

The regression results are constructed to project the effect of changes in mass, independent of all other factors, including footprint. With each additional change from the current environment (e.g., the scale of mass change, presence and prevalence of safety features, demographic characteristics), the results may become less representative. That is, although safety features and demographic factors are accounted for separately, the estimated effects of mass are identified under the specific mix of vehicles and drivers in the data. We note that the analysis accounts for safety features that are optional but available across all MYs in the sample (most notably electronic stability control, which was not yet mandatory for all model years in the

¹⁹³⁹ The agencies use “economically significant results” to mean values that have an important, practical implication, but may be derived from estimates that do not meet traditional levels of statistical significance. For example, if the projected economic benefit of a project equaled \$100 billion, the agencies would consider the impact economically significant, even if the estimates used to derive the impact were not statistically significant at the 95-percent confidence level. Conversely, if the projected economic benefit of a project equaled \$1, the agencies would not consider the impact economically significant, even if the estimates used to derive the impact were statistically significant at the 99.99-percent confidence level. In the case above, we considered the results associated with the lightest and heaviest vehicle types to be economically significant because the associated safety costs were large and the estimates had magnitudes meaningfully different from zero and were statistical significant at the 85-percent confidence level.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

sample), and calibrates historical safety data to account for future fleets with full ESC penetration to reflect the mandate.

The agencies considered the near multicollinearity of mass and footprint to be a major issue in the 2010 Kahane report and voiced concern about inaccurately estimated regression coefficients. High correlations between mass and footprint and variance inflation factors (VIF) have persisted from MY 1991-1999 to MY 2004-2011; large footprint vehicles continued to be, on the average, heavier than small footprint vehicles to the same extent as in the previous decade.

Nevertheless, multicollinearity appears to have become less of a problem in the 2012 Kahane, 2016 Puckett and Kindelberger/Draft TAR, and current analyses. Ultimately, only three of the 27 core models of fatality risk by vehicle type in the current analysis indicate the potential presence of effects of multicollinearity, with estimated effects of mass and footprint reduction greater than two percent per 100-pound mass reduction and one-square-foot footprint reduction, respectively; these three models include passenger cars and CUVs in first-event rollovers, and CUVs in collisions with LTVs greater than 4,360 pounds. This result is consistent with the 2016 Puckett and Kindelberger report, which also found only three cases out of 27 models with estimated effects of mass and footprint reduction greater than two percent per 100-pound mass reduction and one-square-foot footprint reduction.

For comparison, [Table II-98](#)~~Table I-4~~ shows the fatality coefficients from the 2012 Kahane report (MY 2000-2007 vehicles in CY 2002-2008) and the 2016 Puckett and Kindelberger report and Draft TAR (MY 2003-2010 vehicles in CY 2005-2011).

Table II-~~98~~¹⁷⁴ - Fatality Increase (%) per 100-Pound Mass Reduction While Holding Footprint Constant

Vehicle Class ¹⁹⁴⁰	2012 Report Point Estimate	2016 Report/Draft TAR Point Estimate	2012 Report 95% Confidence Bounds	2016 Report 95% Confidence Bounds
Lighter Passenger Cars	1.56	1.49	+.39 to +2.73	-.30 to +3.27
Heavier Passenger Cars	.51	.50	-.59 to 1.60	-.59 to +1.60
CUVs and minivans	-.37	-.99	-1.55 to +.81	-2.17 to +.19
Lighter Truck-based LTVs	.52	-.10	-.45 to +1.48	-1.08 to +.88
Heavier Truck-based LTVs	-.34	-.72	-.97 to +.30	-1.45 to +.02

¹⁹⁴⁰ Median curb weights in the 2012 Kahane report: 3,106 pounds for cars, 4,594 pounds for truck-based LTVs. Median curb weights in the 2016 Puckett and Kindelberger report: 3,197 pounds for cars, 4,947 pounds for truck-based LTVs.

The new results are directionally the same as in 2012; in the 2016 analysis, the estimate for lighter LTVs was of opposite sign (but small magnitude). Consistent with the 2012 Kahane and 2016 Puckett and Kindelberger reports, mass reductions in lighter cars are estimated to lead to increases in fatalities, and mass reductions in heavier LTVs are estimated to lead to decreases in fatalities.

The estimated mass effect for heavier truck-based LTVs is stronger in this analysis and in the 2016 Puckett and Kindelberger report than in the 2012 Kahane report; both estimates are statistically significant at the 85-percent confidence level, unlike the corresponding estimate in the 2012 Kahane report. The estimated mass effect for lighter truck-based LTVs is insignificant and positive in this analysis and the 2012 Kahane report, while the corresponding estimate in the 2016 Puckett and Kindelberger report was insignificant and negative.

Multiple commenters, including the South Coast Air Quality Management District and States and Cities, challenged the practical value of using estimates with statistical significance at the 85-percent level, arguing that below 95 (or 90) percent are insufficiently reliable.¹⁹⁴¹ For example, CARB stated, “[d]ue to the lack of statistical significance, NHTSA should not be attributing any increase in fatalities due to mass reduction” and argues that the “effect of mass reduction on fatality risk should be set to zero since the estimates are not statistically different to zero.”¹⁹⁴²

The agencies believe the updated analysis that was presented in the NPRM represents the most up to date and best estimate of the impacts of mass reduction on crash fatalities; and, that it is appropriate for the analysis to use the best and most likely estimates for safety, even if the estimates are not statistically significant at the 95-percent confidence level. Significance at the 85-percent confidence level is important evidence that the relevant point estimates are meaningfully different to zero (e.g., approximately five to six times more likely to be non-zero than zero). The agencies believe it would be misleading to ignore these data or to use values of zero for the rulemaking analysis, as doing so would not properly inform decision makers on the safety impacts of the regulatory alternatives and final standards. Similar to past analyses, the NPRM and this final rule analysis use the best available estimates. The agencies feel it is inappropriate to ignore likely impacts of the standards simply because the best available estimates have confidence levels below 95 percent; uniform estimates of zero are statistically weaker than the estimates identified in the analysis, and thus are not the best available. Because the point estimates are derived from the best-fitting estimates for each crash type (all of which are non-zero), the confidence bounds around an overall estimate of zero would necessarily be larger than the corresponding confidence bounds around the point estimates presented here.

The sensitivity analysis in [MAIN SENSITIVITY ANALYSIS SECTION] provides an evaluation of extreme cases in which all of the estimated net fatality rate impacts of mass reduction are either at their fifth- or 95th-percentile values. The range of net impacts in the

¹⁹⁴¹ See South Coast Air Quality Management District, Detailed Comments, Docket No. NHTSA-2018-0067-11813, at 6 (internal citation omitted); States and Cities, Detailed Comments, Docket No. NHTSA-2018-0067-11735, at 95.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

sensitivity analysis not only covers the relatively more likely case that uncertain, yet generally offsetting, effects are distinct from the central estimates considered here (e.g., in a plausible case where mass reduction in the heaviest LTVs is less beneficial than indicated by the central estimates, it would also be relatively likely that mass reduction in the lightest passenger cars would be less harmful, yielding a similar net impact), but also covers the relatively unlikely case that all of the estimates are uncertain in the same direction.

At a broader level, multiple commenters asserted that the role of safety-related estimates should be restricted because of what they claim is a weak historical relationship between fuel economy and vehicle safety. For example, the Green Energy Institute at Lewis & Clark Law School commented, “[o]ver the past 40 years, per-capita vehicle fatalities decreased by 50%, while average fuel economy doubled.”¹⁹⁴³ However, this statistic is misleading because it does not account for vehicle safety factors and changes in driving behavior external to fuel economy (e.g., FMVSS and other safe design advances, reductions in drunk driving, increases in seat belt use). That is, fatality rates have decreased due to a range of factors that are unrelated to fuel economy efforts. The methodology in the 2012 Kahane report, the 2016 Puckett and Kindelberger, the Draft TAR, the 2018 NPRM analysis and today’s final rule analysis addresses these other changes in order to isolate the impacts of mass reduction alone. The role of the safety analysis outlined in this document is to isolate incremental effects on safety outcomes that are related to changes in fuel economy.

Multiple commenters disagreed with the results in [Table II-97](#)~~Table I-3~~, maintaining that mass reduction need not reduce societal safety. EDF cited a Michigan Manufacturing Technology Center (MMTC) review as supporting that widespread lightweighting would decrease crash severity through reduced kinetic energy in multiple-vehicle crashes. Similarly, the Aluminum Association commented, “[v]ehicle size, not weight, has been shown to be the leading safety determinant.”¹⁹⁴⁴ Other commenters cited Anderson and Auffhammer (2014), which finds that the safety effects of mass reduction in one vehicle are offset by the safety effects in the crash partner vehicle.¹⁹⁴⁵ The South Coast Air Quality Management District asserted that NHTSA and EPA appear to argue “that fuel-efficient vehicles are lighter than other vehicles, and therefore, less safe.” The North Carolina Department of Environmental Quality asserted that a takeaway from the preferred alternative is that larger vehicles are safer than smaller vehicles. The agencies’ conclusion is that, at the societal level, it is the distribution of changes in vehicle mass that matter (i.e., mitigating mass reduction in the lightest vehicles is societally beneficial, while mitigating mass reduction in the heaviest vehicles is societally harmful).

The 2012 Kahane report, the 2016 Puckett and Kindelberger, the Draft TAR, the 2018 NPRM analysis and today’s final rule analysis all have shown that both mass and vehicle size impact societal safety. Across recent rulemakings, the analyses have confirmed a protective effect of vehicle size (i.e., societal fatality risk decreases as footprint increases). As mentioned

¹⁹⁴³ Green Energy Institute at Lewis & Clark Law School, Docket No. NHTSA-2018-0067-12213, at 3.

¹⁹⁴⁵ Anderson, M.L. and M. Auffhammer (2014). “Pounds that Kill,” *Review of Economic Studies*, Vol. 81, No. 2, pp. 535-71.

previously, the agencies believe vehicle footprint-based standards help to discourage vehicle manufacturers from downsizing their vehicles, and therefore assume changes in CAFE and CO₂ standards will not impact vehicle size and size-related safety impacts. On the other hand, mass reduction is a cost-effective technology for increasing fuel economy and reducing CO₂ emissions. Therefore, the agencies do include the assessment of safety impacts related to mass reduction. As discussed throughout this mass-safety subsection, we present comprehensive consideration of the various studies and workshops on the impact of vehicle mass on safety, and conclude there is in fact a relationship. The fleet simulation study, discussed in the next subsection, further supports the existence of this relationship and that this relationship will continue to exist in future vehicle designs.

The principal difference between heavier vehicles, especially truck-based LTVs, and lighter vehicles, especially passenger cars, is that mass reduction has a different effect in collisions with another car, LTV, or other object such as a lamp post. When two vehicles of unequal mass collide, the change in velocity (delta-V) is greater in the lighter vehicle. Through conservation of momentum, the degree to which the delta-V in the lighter vehicle is greater than in the heavier vehicle is proportional to the ratio of mass in the heavier vehicle to mass in the lighter vehicle:

$$\Delta v_1 = \frac{m_2}{m_1} \Delta v_2$$

Where:

Δv_1 is the delta-V for a focal vehicle,

Δv_2 is the delta-V for a partner vehicle, and

$\frac{m_2}{m_1}$ is the mass of the partner vehicle divided by the mass of the focal vehicle.

Because fatality risk is a positive function of delta-V, the fatality risk in the lighter vehicle in two-vehicle collisions is also higher. Vehicle design can reduce the magnitude of delta-V to some degree (e.g., changing the stiffness of a vehicle's structure could dampen delta-V for both crash partners). These considerations drive the overall result: mass reduction is associated with an increase in fatality risk in lighter cars, a decrease in fatality risk in heavier LTVs, CUVs, and minivans, and has smaller effects in the intermediate groups. Mass reduction may also be harmful in a crash with a movable object such as a small tree, which may break if hit by a high mass vehicle resulting in a lower delta-V than may occur if hit by a lower mass vehicle which does not break the tree and therefore has a higher delta-V. However, in some types of crashes not involving collisions between cars and LTVs, especially first-event rollovers and impacts with fixed objects, mass reduction may not be harmful and may even be beneficial.

Ultimately, delta-V is a direct function of relative vehicle mass for given vehicle structures. Removing some mass from the heavier vehicle involved in an accident with a lighter vehicle reduces the delta-V in the lighter vehicle, where fatality risk is higher, resulting in a large benefit to the passengers of the lighter vehicle. This is partially offset by a small increase in the

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

delta-V in the heavy vehicle; however, the fatality risk is lower in the heavier vehicle and remains relatively low despite the increase in delta-V. In sum, the change in mass and delta-V from mass reduction in heavier vehicles results in a net societal benefit.

Multiple commenters claimed that the agencies' analysis does not allow for the likely outcome that mass reduction would be concentrated among relatively heavy vehicles.¹⁹⁴⁶ For example, Global Automakers commented that the agencies should not include weight reduction in their safety analysis because "very few vehicles [have] implemented lightweight material substitution strategies."¹⁹⁴⁷

Neither CAFE standards nor this analysis mandate mass reduction, or mandate mass reduction occur in any specific manner. However, mass reduction is a highly cost effective technology for improving fuel economy and CO₂ emissions. The steel, aluminum, plastics, composite, and other material industries are developing new materials and manufacturing equipment and facilities to produce those materials. In addition, suppliers and manufacturers are optimizing designs to maintain or improve functional performance with lower mass. Manufacturers have stated that they will continue to reduce vehicle mass to meet more stringent standards, and therefore, this expectation is incorporated into the modeling analysis supporting the standards to: (1) determine capabilities of manufacturers; and (2) to predict costs and fuel consumption effects of CAFE standards. The CAFE and CO₂ rulemakings in 2012, the Draft TAR and EPA Preliminary Determination, imposed an artificial constraint on vehicle mass reduction to achieve a desired safety-neutral outcome. For the current rulemaking, this artificial constraint is eliminated so the analysis reflects manufacturers applying the most cost effective technologies to achieve compliance with the regulatory alternatives and the final standards; this approach allows mass reduction to be applied across the fleet. This is consistent with industry trends.¹⁹⁴⁸ To the extent that mass reduction is only cost-effective for the heaviest vehicles, the CAFE model would create the outcome predicted by commenters. In reality, however, mass reduction is a cost-effective means of improving fuel economy and does take place across vehicles of all sizes and weights. Accordingly, the model reflects that manufacturers may reduce vehicle mass—regardless of vehicle class—when doing so is cost effective.

The National Tribal Air Association claimed the 2015 NAS study found "evidence suggest[ing] that the [2012] standards will lead the nation's light-duty vehicle fleet to become lighter but not less safe."¹⁹⁴⁹ The agencies note the NAS quote is one phrase from the press

release that accompanied the NHTSA sponsored 2015 NAS study,¹⁹⁵⁰ and the agencies do not believe the phrase in isolation reflects the findings of the NAS Committee, which are discussed in over 3 pages of the report.¹⁹⁵¹ The 2015 NAS report supported the analytical methodology used for the 2012 NHTSA CAFE and EPA CO₂ rulemaking and found it reasonable. As discussed in the subsections further above, a nearly identical methodology was used for the NPRM analysis and for this final rule.

The agencies received several comments about the relationship between mass and crash avoidance. The NRDC commented that the analysis should account for the expected result that mass reduction makes it easier to avoid crashes.¹⁹⁵² Conversely, IPI quoted a finding by LNL that “found that mass reductions may increase the number of accidents but that each crash results in fewer fatalities.”¹⁹⁵³

The phenomenon touched upon by IPI and NRDC has been identified in past rulemakings as well, and highlights that the relationship between mass reduction and societal fatality risk include two partially-offsetting components (i.e., increased exposure to crashes is offset partially by decreased risk in some vehicles conditional on a crash occurring). The agencies note that this relationship, while not reported separately, is in fact embedded within the analysis detailed in this document, as the extent to which some vehicles are more maneuverable and faster-braking, the crash data reflect those characteristics through lower observed fatality rates. However, when considering the purposes of estimating effects of mass reduction on fatalities, it is immaterial what share of the effect is comprised of crash avoidance factors and crashworthiness factors, the ultimate effect is present within the data evaluated in the analysis. The mass-safety impacts estimated by the statistical analysis of crash data are based on the safety technologies and mass levels present among the vehicle fleets for the calendar and model years in the data. As discussed below in this section, the analysis separately accounts for the effects of future safety technologies.

(4) Sensitivity Analysis

Table II-99Table I-5 shows the principal findings and includes sampling-error confidence bounds for the five parameters used in the CAFE model. The confidence bounds represent the statistical uncertainty that is a consequence of having less than a census of data. NHTSA’s 2011, 2012, and 2016 reports acknowledged another source of uncertainty: The central (baseline)

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

statistical model can be varied by choosing different control variables or redefining the vehicle classes or crash types, which for example, could produce different point estimates.

Beginning with the 2012 Kahane report, NHTSA has provided results of 11 plausible alternative models that serve as sensitivity tests of the baseline model. Each alternative model was tested or proposed by: Farmer (IIHS) or Green (UMTRI) in their peer reviews; Van Auken (DRI) in his public comments; or Wenzel in his parallel research for DOE. The 2012 Kahane and 2016 Puckett and Kindelberger reports provide further discussion of the models and the rationales behind them.

Alternative models use NHTSA's databases and regression-analysis approach but differ from the central model in one or more explanatory variables, assumptions, or data restrictions. We applied the 11 techniques to the latest databases to generate alternative CAFE model coefficients. The range of estimates produced by the sensitivity tests offers insight to the uncertainty inherent in the formulation of the models, subject to the caveat that these 11 tests are, of course, not an exhaustive list of conceivable alternatives.

The central and alternative results follow, ordered from the lowest to the highest estimated increase in societal risk per 100-pound reduction for cars weighing less than 3,201 pounds:

Table II-99172 - Fatality Increase (%) Per 100-Pound Mass Reduction While Holding Footprint* Constant

		Cars	Cars	CUVs &	LTVs†	LTVs†
		< 3,201	≥ 3,201	Minivans	< 5,014	≥ 5,014

*While holding track width and wheelbase constant (rather than footprint) in alternative model nos. 2 and 3.

[†]Excluding CUVs and minivans.

[‡]BAC=0, no drugs, valid license, at most one crash and one violation during the past three years.

For example, in cars weighing less than 3,201 pounds, the baseline estimate associates 100- pound mass reduction, while holding footprint constant, with a 1.56 percent increase in societal fatality risk. The corresponding estimates for the 11 sensitivity tests range from a 0.26 to a 2.15 percent increase.

The sensitivity tests illustrate both the fragility and the robustness of central estimates. On the one hand, the variation among the coefficients is quite large relative to the central estimate: in the preceding example of cars < 3,201 pounds, the estimated coefficients range from almost zero to almost double the central estimate. This result underscores the key relationship that the societal effect of mass reduction is small. In other words, varying how to model some of these other vehicle, driver, and crash factors, which is exactly what sensitivity tests do, can appreciably change the estimate of the societal effect of mass reduction.

On the other hand, variations are not particularly large in absolute terms. The ranges of alternative estimates are generally in line with the sampling-error confidence bounds for the central estimates. Generally, in alternative models as in the central model, mass reduction tends to be relatively more harmful in the lighter vehicles and more beneficial in the heavier vehicles, just as they are in the central analysis. In all models, the point estimate of the coefficient is positive for the lightest vehicle class, cars < 3,201 pounds. In 10 out of 11 models, the point estimate is negative for CUVs and minivans, and in nine out of 11 models the point estimate is negative for LTVs $\geq 5,014$ pounds. We believe the central case uses the most rigorous methodology, as discussed further above, and provides the best estimates of the impacts of mass reduction on safety.

Tom Wenzel commented confirming a preference for the alternative model with footprint separated into track width and wheelbase, and with the induced exposure data limited to stopped vehicle cases.¹⁹⁵⁴ Wenzel asserts that splitting footprint into its components reduces multicollinearity with curb weight, and that limiting induced exposure cases to stopped vehicles mitigates bias against driver-vehicle pairs that are less likely to be involved in crashes. Based on this feedback and the intuitiveness of the approach, we further considered the alternative model with footprint split into track width and wheelbase. Consistent with previous analyses and assessments, there are problems with splitting footprint into its components within the mass-size-safety models because of strong correlations among curb weight, track width and wheelbase. For all vehicle classes in the analysis, curb weight is correlated either nearly as high or higher with track width as with footprint. Track width and wheelbase are also highly correlated with one another (ranging from around 0.64 to 0.80, with the exceptions of smaller correlations for large

¹⁹⁵⁴¹⁹⁵⁴ Wenzel, T., Lawrence Berkeley National Laboratories, Docket No. EPA-HQ-OAR-2018-0283-4118.

pickups and minivans). Viewed from another angle, wheelbase is almost perfectly correlated with footprint (with correlations ranging from around 0.95 to 0.97).

Considered in concert, the track width and wheelbase model not only essentially incorporates the full correlation issues from the baseline model (curb weight highly correlated with another independent variable), but also adds a further correlation issue (the variable that is highly correlated with curb weight is also highly correlated with a separate independent variable). We examined supplementary means of confirming the relative methodological merit of the footprint-based model and the track-width-wheelbase-based alternative. The supplementary analysis centered on the *condition index*, which quantifies the invertibility of the matrix of independent variables in a given model through its measure, the *condition number*.¹⁹⁵⁵ A model with a low condition number has relatively low correlations among its independent variables, and thus its invertibility and the corresponding model outputs are robust to variations in model input values. A model with a high condition number has relatively high correlations among its independent variables, and thus its invertibility and model outputs are *not* robust to variations in model input values. That is, a model with a high condition number is likely to be subject to the problems associated with multicollinearity. Although there is no strict threshold condition number value to indicate multicollinearity, higher values indicate greater likelihood that the independent variables are correlated to a problematic degree.

The condition index offers an alternative means of capturing the same forces as the variance inflation factor (VIF), which the agencies have used historically (including in this rulemaking) as a diagnostic of multicollinearity. However, the condition index offers some advantages relative to the VIF. Notably, the condition index applies regardless of the econometric form of the model (i.e., the decomposition of the independent variables is the same regardless of how the variables are applied in the model). This is distinct from the VIF, which is limited to a linear diagnostic of the data that may not map well to non-linear econometric models, including the logistic regression models that form the core of the curb weight-fatality risk analysis. The condition index estimates the incremental effects of individual variables, which is helpful in an analysis of which independent variables are the most problematic. Conversely, the diagnostic values from the VIF are not necessarily sensitive to incremental correlated variables, as the VIF value ($1/(1-R^2)$) does not necessarily change much once correlations are relatively high (i.e., when R^2 is already high, the inclusion of one or more highly correlated variables may not change R^2 , and in turn, the VIF, by much).

An incremental comparison of VIF estimates for the data confirmed the potential weakness of the VIF in this case. For the CUV-minivan model data, the VIF *decreases* from 9.4 to 6.7 when: (1) substituting either track width or footprint for footprint that has an identical correlation with curb weight as footprint; and (2) adding the other component of footprint. This

¹⁹⁵⁵ See Belsley, D. A., Kuh, E., and Welsch, R. E. (1980). "The Condition Number". *Regression Diagnostics: Identifying Influential Data and Sources of Collinearity*. New York: John Wiley & Sons; Freund, R.J. and Littell, R.C. (2000). *SAS System for Regression, Third Edition*. Cary, NC: SAS Institute, Inc.; and Hallahan, C. (1995). "Understanding the Multicollinearity Diagnostics in SAS/Insight and Proc Reg." SAS Conference Proceedings, Washington, DC, October 8-10, 1995.

result is counterintuitive (i.e., the simpler model should necessarily have fewer issues of multicollinearity), and may be an artifact of differences in model fit (e.g., a higher R^2 in the simpler model could indicate better model fit rather than anything problematic in terms of correlation structure). This result led the agencies to question how well the VIF identifies relative impacts of multicollinearity across related models, especially in non-linear applications.

The calculated condition numbers for the curb weight-footprint models and their corresponding curb weight-wheelbase-track width alternatives were consistent with expectations regarding multicollinearity, however. The condition numbers for the curb weight-wheelbase-track width models are approximately two to three times higher than the condition numbers for the curb weight-footprint models. This indicates that the level of imprecision in model estimates using track width and wheelbase would be expected to be between approximately two to three times higher than in the baseline models using footprint. Unlike the VIF, the condition index supports a hypothesis that multicollinearity would not be mitigated in an alternative with disaggregated variables that are highly correlated with both the variable of interest and the variable they are replacing. Considering these results, the agencies that using footprint to represent vehicle size in the safety models provides a more reliable estimate of safety impacts than splitting footprint into track width and wheelbase.

The agencies also considered the use of stopped-vehicle data as an alternative. The primary problem with this approach is that we do not observe as large of a share of cases on roads with higher travel speeds (e.g., interstate highways) when including only stopped vehicles; this relationship influences the extent to which the induced exposure data reflect the distributions of driver attributes and contextual effects across national VMT. Based on this assessment, the agencies believe the methodology used for the analysis in the proposal provides a more reliable and representative estimate of safety impacts, and thus is not changing the methodology for today's final rule.

In a related comment, Wenzel proposes that future analyses should directly account for differences in curb weight between vehicles in two-vehicle crashes. The agencies believe that would require the development of a model that directly accounts for the relative weights of vehicles in two-vehicle crashes, and that such a model would require peer review. Key alternatives to test would vary in terms of the functional form of the mass disparity between two crash partners (e.g., a relative mass ratio consistent with the delta-V calculation presented above, linear mass difference, non-linear mass difference). We will consider initiating work to explore such a model in the future.

DRI requested the agencies clarify whether the analysis accounts for all road users (i.e., including pedestrians, bicyclists, motorcyclists, and other crash partners), while the Pennsylvania Department of Environmental Protection commented, "[i]t is inadequate for the agencies' analysis for this Proposed Rule to only focus on frontal crashes while omitting near-frontal collisions, side-impact collisions, rear-end collisions, rollover accidents, impacts with stationary

objects and accidents involving pedestrians.”¹⁹⁵⁶ The agencies confirm that the analysis presented in this section continues to apply the methodology developed by Kahane, which incorporates all road users, without double-counting, to identify societal fatality rate impacts. Because every fatal crash (across crash types) is included in the analysis, not just frontal crashes, the agencies find this comment lacks a basis. We believe the commenter’s confusion may stem from the use of front-to-back crashes to generate estimates of the proportions of all driving for each vehicle model associated with particular characteristics of drivers (e.g., age, gender) and crashes (e.g., urban/rural, day/night). These crashes represent the best available trade-off among sample size, representativeness of overall vehicle and driver exposure, and mitigating bias in a sample that is intended to be effectively random (i.e., the probability of being struck from behind by an at-fault driver is assumed to be a function of characteristics of other drivers and travel demand, but not of the struck driver or the struck vehicle).

(5) *Fleet Simulation Study*

Commenters to recent CAFE rulemakings, including some vehicle manufacturers, have suggested designs and materials of more recent model year vehicles may have weakened the historical statistical relationships between mass, size, and safety. NHTSA and EPA agreed that the statistical analysis would be improved by using an updated crash and exposure database reflecting more recent safety technologies, vehicle designs and materials, and reflecting changes in the vehicle fleet. As mentioned above, a new crash and exposure database was created with the intention of capturing modern vehicle engineering and has been employed for assessing safety effects for CAFE rules since 2012.

The agencies have traditionally relied solely on real-world crash data as the basis for projecting the future safety implications for regulatory changes. The agencies are required to consider relevant data in setting standards.¹⁹⁵⁷ Every fleet regulated by the agencies’ standards differs from the fleet used to establish said standard, and as such, the light-duty vehicle fleet in the MY 2021-2026 timeframe will be different from the MY 2004-2011 fleet analyzed above. This is not a new or unique phenomenon, but instead is an inherent challenge in regulating an industry reliant on continual innovation. This is the agencies’ sixth evaluation of effects of mass reduction and/or downsizing,¹⁹⁵⁸ comprising databases ranging from MYs 1985 to 2011. Despite

¹⁹⁵⁶ Pennsylvania Department of Environmental Protection, Detailed Comments, Docket No. NHTSA-2018-0067-11956, at 9.

¹⁹⁵⁷ See *Center for Biological Diversity v. NHTSA*, 538 F.3d 1172, 1203 (9th Cir. 2008).

¹⁹⁵⁸ As outlined throughout this section, NHTSA’s six related studies include the new analysis supporting this rulemaking, and: Kahane, C. J. *Vehicle Weight, Fatality Risk and Crash Compatibility of Model Year 1991-99 Passenger Cars and Light Trucks*, National Highway Traffic Safety Administration (Oct. 2003), available at <https://crashstats.nhtsa.dot.gov/Api/Public/ViewPublication/809662>; Kahane, C. J. *Relationships Between Fatality Risk, Mass, and Footprint in Model Year 1991-1999 and Other Passenger Cars and LTVs* (Mar. 24, 2010), in *Final Regulatory Impact Analysis: Corporate Average Fuel Economy for MY 2012-MY 2016 Passenger Cars and Light Trucks*, National Highway Traffic Safety Administration (Mar. 2010) at 464-542; Kahane, C. J. *Relationships Between Fatality Risk, Mass, and Footprint in Model Year 2000-2007 Passenger Cars and LTVs – Preliminary Report*, National Highway Traffic Safety Administration (Nov. 2011), available at Docket ID NHTSA-2010-0152-

continual claims that modern lightweight engineering will render current data obsolete, results of the six studies, while not identical, have been generally consistent in showing a small, negative impact related to mass reduction. The agencies strongly believe that real-world crash data remains the best, relevant data to measure the effect of mass reduction on safety.

However, because lightweight vehicle designs introduce fundamental changes to the structure of the vehicle, there remains a persistent question of whether historical safety trends will apply. To address this concern and to verify that real-world crash data remain an appropriate source of data for projecting mass-safety relationships in the future fleet, in 2014, NHTSA sponsored research to develop an approach to utilize experimental lightweight vehicle designs to evaluate safety in a broader range of real-world representative crashes.¹⁹⁵⁹ NHTSA contracted with George Washington University to perform a fleet simulation model to study the impact and relationship of light-weighted vehicle design with injuries and fatalities.¹⁹⁶⁰ The study involved simulating crashes on eight test vehicles, five of which were equipped with lightweight materials and advanced designs not yet incorporated into the U.S. fleet. The study assessed a range of frontal crashes, including crashes with fixed objects and other vehicles, across wide range of vehicle speeds, and with mid-size male and mid-size female dummies.¹⁹⁶¹ In all, more than 440 vehicle crashes with 1,520 dummy passengers were simulated for a range of crash speeds and crash configurations. Results from the fleet simulation study showed the trend of increased societal injury risk for light-weighted vehicle designs occurs for both single vehicle and two-vehicle crashes. Results are listed in [Table II-100](#)~~Table I-6~~.¹⁹⁶²

Table II-~~100~~⁴⁷³ - Overall Societal Risk Calculation Results for Model Runs, with Base Vehicle Restraint and Airbag Settings Being the same for All Vehicles, in Frontal Crash Only

The change in the safety risk from the fleet simulation study was directionally consistent with results for passenger cars from the 2012 Kahane report,¹⁹⁶³ the 2016 Puckett and Kindelberger report, and the analysis used for the proposal and today's final rule. As noted, fleet simulations were performed in frontal crash mode and did not consider other crash modes such as rollover crashes.¹⁹⁶⁴ The fleet simulation analysis confirmed that real-world crash data were still a reliable source for analyzing mass safety impacts.

Despite the results of the fleet simulation analysis, which was republished in the proposal, the agencies received additional comments questioning the assumption that relationships among vehicle mass, size, and fatality risk will continue in the future. For example, the Alliance for Vehicle Efficiency asserted that using lighter frame materials has no impact on safety, noting that any mass reduction strategies are applied to components that are unrelated to crash safety and crash ratings have not declined for vehicles over the past five years.¹⁹⁶⁵ CARB commented that the agencies did not account for new vehicle improvements and claimed the data used for the analysis was "not a good indicator of the safety performance of future purpose-designed lightweighted vehicles."¹⁹⁶⁶ Consumers Union offered a similar appraisal, indicating that the MYs in the sample are "unlikely to capture the current and future mass/fatality relationship of modern vehicles."¹⁹⁶⁷ While the Aluminum Association commented vehicle size,

¹⁹⁶³ The 2012 Kahane study considered only fatalities, whereas, the fleet simulation study considered severe (AIS 3+) injuries and fatalities (DOT HS 811 665).

¹⁹⁶⁴ The risk assessment for CUV in the regression model combined CUVs and minivans in all crash modes and included belted and unbelted occupants.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

not mass, is the only physical feature that impacts safety.¹⁹⁶⁸ The American Chemistry Council, Hyundai, and Tesla commented that it is feasible to utilize design improvements and technologies to offset the incremental risk for vehicle occupants associated with mass reduction.¹⁹⁶⁹ EDF said the mass-safety analysis did not agree with conclusions from a study by the Michigan Manufacturing Technology Center.¹⁹⁷⁰ Comments from States and Cities, American Honda, ICCT, and NRDC shared these sentiments.¹⁹⁷¹

These comments and the MMTC study ignored the results of the fleet simulation study and seem premised on the notion that a vehicles' performance on NHTSA FMVSS, NHTSA voluntary NCAP, and IIHS voluntary safety tests is the only measure for assessing societal safety impacts for mass reduction. The regulatory and consumer information tests are representative of real-world, single-vehicle crash configurations. However, the tests are performed at constant speeds, and the dummy occupant is generally a mid-size male. In the real world, crashes occur at various impact velocities and configurations; with various impact partners (e.g., rigid obstacles, lighter or heavier vehicles); and involve occupants of various sizes and ages. The fleet simulation study, summarized above, assessed additional types of frontal crashes, including crashes with fixed objects and other vehicles at a wide range of vehicle speeds, and with mid-size male and mid-size female dummies. The fleet simulation study was more comprehensive and focused on the need to assess overall societal safety impacts. The fleet simulation study found that vehicle mass does impact safety with future lightweight vehicle designs that perform well on regulatory and consumer information tests.

The agencies received one comment regarding the fleet simulation analysis. CARB commented that the analysis tested too few vehicles and crash types, should have optimized restraints in the lightweighted models to simulate future safety improvements instead of using modern restraints, and lacked credibility because the results of the fleet simulation analysis did not reproduce the same results of other studies.¹⁹⁷² CARB's comments demonstrate a general misunderstanding of the fleet simulation analysis; the analysis was not intended to serve as a prediction of how the future vehicle fleet will perform, but rather was an exploration of whether expected lightweighting techniques would alter the dynamic between mass reduction and safety. The analysis was not an attempt to model every potential vehicle construction or crash scenario. Attempting to simulate every future crash would be impractical and ineffective. The

¹⁹⁷² CARB, Detailed Comments, Docket No. NHTSA-2018-0067-11873, at 272-73.

combination of vehicles and crash simulations were purposely selected to provide the strongest insight into the effective of lightweighting techniques. For passenger cars and light trucks, frontal crashes account for 58 percent of fatal crashes;¹⁹⁷³ it is appropriate to focus research on understanding the effects of mass reduction where the largest issue exists. For the study, the use of generic restraint systems as the foundations for the models was intentional so that the models would be more representative of a vehicle class rather than a specific vehicle. The models of the restraint systems represented designs currently in production at time of the study in terms of pretensioners, load limiters and air bag inflators. It is worth noting that in general, driver air bags are similar in most vehicles. And finally, the analysis was not an attempt to reproduce the 2012 Kahane report or any other study. The fact that the fleet simulation analysis showed mass-reduction to be detrimental in more types of vehicles than in the FARS data only further highlights the need to consider how today's standards may impact mass-safety. While in the future there may be resources and opportunity to expand the fleet simulation approach to other crash scenarios and, if they become available, to include additional vehicle mass reduction concepts, the lack of potential future data does not justify ignoring the data that currently exist.

From a higher perspective, the comments, and in particular CARB's comment, identify the problem with abandoning real-world crash data: there is no alternate methodology or data that can account for the full diversity of crash scenarios that occur in the real world. Real-world crash data is the only data type that can achieve that. Therefore, the agencies have determined that, while simulations can prove helpful to understanding potential effects of key crash scenarios and as a check on the agencies' preferred analysis, real-world data still is still the best, most relevant data available for assessing safety.

(6) *Summary of Mass Safety Impacts*

Table II-101 Table I-7 through Table II-106 Table I-12 show results of NHTSA's vehicle mass-size-safety analysis over the cumulative lifetime of MY 1977-2029 vehicles, for both the CAFE and CO₂ programs, based on the MY 2017 baseline fleet, accounting for the projected safety baselines. Results are driven extensively by the degree to which mass is reduced in relatively light passenger cars and in relatively heavy vehicles because their coefficients in the logistic regression analysis have the most significant values. We assume any impact on fatalities will occur over the lifetime of the vehicle, and the chance of a fatality occurring in any particular year is directly related to the weighted vehicle miles traveled in that year.

As shown in the tables above, all of the alternatives are estimated to lead to a decrease in the number of mass-related fatalities over the cumulative lifetime of MY 1977-2029 vehicles. The effects of mass changes on fatalities range from a combined decrease (relative to the augural standards, the baseline) of 143 fatalities for Alternative #7 to a combined decrease of 288 fatalities for Alternatives #1 and #2. The difference in results by alternative depends upon how much weight reduction is used in that alternative and the types and sizes of vehicles to which the weight reduction applies. The decreases in fatalities are driven by impacts within passenger cars (decreases of between 167 and 380 fatalities) and are offset by impacts within light trucks (increases of between 9 and 92 fatalities).

Changes in vehicle mass are estimated to decrease social safety costs over the lifetime of the nine model years by between \$2.5 billion (for Alternative #7) and \$5.1 billion (for Alternatives #1 and #2) relative to the augural standards at a three-percent discount rate and by between \$1.5 billion and \$3.1 billion at a seven-percent discount rate. The estimated decreases in social safety costs are driven by estimated decreases in costs associated with passenger cars, ranging from \$3.0 billion (for Alternative #7) to \$6.7 billion (for Alternatives #1 and #2) relative to the augural standards at a three-percent discount rate and by between \$1.8 billion and \$4.0 billion at a seven-percent discount rate. The estimated decreases in costs associated with passenger cars are offset partially by estimated increases in costs associated with light trucks, ranging from \$0.1 billion (for Alternative #5) to \$1.6 billion (for Alternatives #1 and #2) relative to the Augural standards at a three-percent discount rate and by between \$0.1 billion and \$0.9 billion at a seven-percent discount rate.

In this analysis, the profile of mass reduction across vehicle models leads to a small, but beneficial effect on fatalities as fuel economy standards are tightened. [Table II-125](#)~~Table I-13~~ through [Table II-112](#)~~Table I-18~~ present average annual estimated safety effects of vehicle mass changes, for CYs 2036-2045. The CY-level values offer a complementary view of the impacts of fuel economy standards on mass-related fatalities relative to model-year-level results. Effects by CY over the interval selected (2036-2045) enable a summary view of (a flow of) annual fatality impacts during a period where vehicles subjected to the standards have not only fully entered the fleet, but also interact with both older and newer vehicles. Conversely, the MY-level values offer a summary view of (a stock of) the impacts of fuel economy standards for the lifetime of a given MY:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

For all light-duty vehicles, mass changes are estimated to lead to an average annual decrease in fatalities in all alternatives evaluated for CYs 2035-2045. The effects of mass changes on fatalities range from a combined decrease (relative to the augural standards) of 20 fatality per year for Alternative #7 to a combined decrease of 37 fatalities per year for Alternative #4. The difference in the results by alternative depends upon how much weight reduction is used in that alternative and the types and sizes of vehicles to which the weight reduction applies. The decreases in fatalities are generally driven by impacts within passenger cars (decreases of between 22 and 50 fatalities per year relative to the augural standards) and are offset by impacts within light trucks (increases of between 2 and 12 fatalities per year).

Changes in vehicle mass are estimated to decrease average annual social safety costs in CY 2035-2045 by between \$0.3 billion (for Alternative #7) and \$0.6 billion (for Alternative #4) at a three-percent discount rate relative to the augural standards (decrease of between \$0.1 and \$0.2 billion at a seven-percent discount rate). Average annual social safety costs associated with passenger cars in CY 2035-2045 are estimated to decrease by between \$0.3 billion and \$0.7 billion at a three-percent discount rate (decrease of between \$0.1 billion and \$0.3 billion at a seven-percent discount rate), but this effect is partially offset by a corresponding increase in costs associated with light trucks (increase of \$0.2 billion or less across alternatives at three-percent and seven-percent discount rates).

To help illuminate effects at the model year level, [Table II-131](#)~~Table I-19~~ presents the lifetime fatality impacts associated with vehicle mass changes for passenger cars, light trucks, and all light-duty vehicles by model year under the preferred alternative, relative to the augural standards for the CAFE Program. [Table II-132](#)~~Table I-20~~ presents an analogous table for the CO₂ Program.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Under the preferred alternative, passenger car fatalities associated with mass changes are estimated to decrease relative to the augural standards steadily from MYs 2018-19 (decrease of 5 fatalities) through MY 2028 (decrease of 53 fatalities). Conversely, light truck fatalities associated with mass changes under the preferred alternative are estimated to increase relative to the augural standards from MY 2019 (increase of 2 fatalities) through MY 2029 (increase of 9 fatalities).

Table II-133~~Table I-21~~ and Table II-134~~Table I-22~~ present estimates of monetized lifetime social safety costs associated with mass changes by model year at three-percent and seven-percent discount rates, respectively for the CAFE Program.

Table II-135~~Table I-23~~ and Table II-136~~Table I-24~~ show comparable tables from the perspective of the CO₂ Program.

Lifetime social safety costs associated with mass change in passenger cars are estimated to decrease by between \$0.1 billion (for MYs 2020-22) and \$0.3 billion (for MYs 2026-29) at a three-percent discount rate. At a seven-percent discount rate, lifetime social safety costs associated with mass change in passenger cars are estimated to decrease by between \$0.1 billion and \$0.2 billion from MY 2021 through MY 2029. Lifetime social safety costs associated with mass change in light trucks are estimated to increase by \$0.1 billion or less for all MYs at three-percent and seven-percent discount rates.

As shown in the tables above, all of the alternatives are estimated to lead to a decrease in the number of mass-related fatalities over the cumulative lifetime of MY 1977-2029 vehicles. The effects of mass changes on fatalities range from a combined decrease (relative to the augural standards, the baseline) of 126 fatalities for Alternative #7 to a combined decrease of 253 fatalities for Alternatives #1 and #2. The difference in results by alternative depends upon how much weight reduction is used in that alternative and the types and sizes of vehicles to which the weight reduction applies. The decreases in fatalities are driven by impacts within passenger cars (decreases of between 146 and 33 fatalities) and are offset by impacts within light trucks (increases of between 8 and 81 fatalities).

Changes in vehicle mass are estimated to decrease social safety costs over the lifetime of the nine model years by between \$2.2 billion (for Alternative #7) and \$4.5 billion (for Alternatives #1 and #2) relative to the augural standards at a three-percent discount rate and by between \$1.3 billion and \$2.7 billion at a seven-percent discount rate. The estimated decreases in social safety costs are driven by estimated decreases in costs associated with passenger cars, ranging from \$2.6 billion (for Alternative #7) to \$5.9 billion (for Alternatives #1 and #2) relative to the Augural standards at a three-percent discount rate and by between \$1.6 billion and \$3.5 billion at a seven-percent discount rate. The estimated decreases in costs associated with passenger cars are offset partially by estimated increases in costs associated with light trucks, ranging from \$0.1 billion (for Alternative #5) to \$1.4 billion (for Alternatives #1 and #2) relative to the Augural standards at a three-percent discount rate and by between \$0.1 billion and \$0.8 billion at a seven-percent discount rate.

In this analysis, the profile of mass reduction across vehicle models leads to a small, but beneficial effect on fatalities as fuel economy standards are tightened. [Table II-125](#)~~Table VI-185~~ through [Table II-130](#)~~Table VI-190~~ present average annual estimated safety effects of vehicle mass changes, for CYs 2035-2045:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

For all light-duty vehicles, mass changes are estimated to lead to an average annual decrease in fatalities in all alternatives evaluated for CYs 2035-2045. The effects of mass changes on fatalities range from a combined decrease (relative to the augural standards) of 17 fatality per year for Alternative #7 to a combined decrease of 34 fatalities per year for Alternative #4. The difference in the results by alternative depends upon how much weight reduction is used in that alternative and the types and sizes of vehicles to which the weight reduction applies. The decreases in fatalities are generally driven by impacts within passenger cars (decreases of between 19 and 44 fatalities per year relative to the augural standards) and are offset by impacts within light trucks (increases of between 2 and 11 fatalities per year).

Changes in vehicle mass are estimated to decrease average annual social safety costs in CY 2035-2045 by between \$0.2 billion (for Alternative #7) and \$0.5 billion (for Alternative #4) at a three-percent discount rate relative to the augural standards (decrease of between \$0.1 and \$0.2 billion at a seven-percent discount rate). Average annual social safety costs associated with passenger cars in CY 2035-2045 are estimated to decrease by between \$0.3 billion and \$0.6 billion at a three-percent discount rate (decrease of between \$0.1 billion and \$0.3 billion at a seven-percent discount rate), but this effect is partially offset by a corresponding increase in costs associated with light trucks (increase of \$0.1 billion or less across alternatives at three-percent and seven-percent discount rates).

To help illuminate effects at the model year level, [Table II-131](#)~~Table VI-191~~ presents the lifetime fatality impacts associated with vehicle mass changes for passenger cars, light trucks, and all light-duty vehicles by model year under the preferred alternative, relative to the Augural standards for the CAFE Program. [Table II-132](#)~~Table VI-192~~ presents an analogous table for the CO₂ Program.

Under the preferred alternative, passenger car fatalities associated with mass changes are estimated to decrease relative to the augural standards steadily from MYs 2018-19 (decrease of 4 fatalities) through MYs 2028-29 (decrease of 46 fatalities). Conversely, light truck fatalities associated with mass changes under the preferred alternative are estimated to increase relative to the augural standards from MY 2019 (increase of 1 fatality) through MY 2029 (increase of 8 fatalities).

Table II-133~~Table VI-193~~ and Table II-134~~Table VI-194~~ present estimates of monetized lifetime social safety costs associated with mass changes by model year at three-percent and seven-percent discount rates, respectively for the CAFE Program.

Table II-135~~Table VI-195~~ and Table II-136~~Table VI-196~~ show comparable tables from the perspective of the CO₂ Program.

Lifetime social safety costs associated with mass change in passenger cars are estimated to decrease by between \$0.1 billion (for MYs 2020-23) and \$0.3 billion (for MYs 2026-29) at a three-percent discount rate. At a seven-percent discount rate, lifetime social safety costs associated with mass change in passenger cars are estimated to decrease by between \$0.1 billion and \$0.2 billion from MY 2022 through MY 2029. Lifetime social safety costs associated with mass change in light trucks are estimated to increase by less than \$0.1 billion for all MYs at three-percent and seven-percent discount rates.

b) Impact of Vehicle Prices on Fatalities

The sales and scrappage responses discussed above have important safety consequences and influence safety outcomes through the same basic mechanism, fleet turnover. In the case of the scrappage response, delaying fleet turnover keeps drivers in older vehicles which are less safe than newer vehicles. Similarly, the sales response slows the rate at which newer vehicles, and their associated safety improvements, enter the on-road population. The sales response also influences the mix of vehicles on the road—with more stringent CAFE standards leading to a higher share of light trucks sold in the new vehicle market, assuming all else is equal. Light trucks have higher rates of fatal crashes when interacting with passenger cars and, as earlier sections discussed, different directional responses to mass reduction technology based on the existing mass and body style of the vehicle.¹⁹⁷⁴

With an integrated fleet model now part of the analytical framework for CAFE analysis, any effects on fleet turnover (either from delayed vehicle retirement or deferred sales of new vehicles) will affect the distribution of both ages and model years present in the on-road fleet. Because each of these vintages carries with it inherent rates of fatal crashes, and newer vintages are generally safer than older ones, changing that distribution will change the total number of on-road fatalities under each regulatory alternative. Similarly, the dynamic fleet share model captures the changes in the fleet's composition of cars and trucks. As cars and trucks have different fatality rates, differences in fleet composition across the alternatives will affect fatalities.

At the highest level, the agencies calculate the impact of the sales and scrappage effects by multiplying the VMT of a vehicle by the fatality risk of that vehicle. For this analysis, calculating VMT is rather simple: the agencies use the distribution of miles calculated in Section 6. The trickier aspect of the analysis is creating fatality rate coefficients. The fatality risk measures the likelihood that a vehicle will be involved in fatal accident per mile driven. As explained below, the agencies' methodology changed from the proposal to this final rule in response to comments, but the basic analytical framework remains the same. The agencies calculate the fatality risk of a vehicle based on the vehicle's model year, age, and style, while controlling for factors which are independent of the intrinsic nature of the vehicle, such as behavioral characteristics.

¹⁹⁷⁴ See Section 6. Analytical Approach as Applied to Regulatory Alternatives] for a full explanation of the sales and scrappage effects and how they are modeled.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(1) *How the Agencies Modeled Impacts of Vehicle Scrappage and Sales on Fatalities in the NPRM*

In the proposal, the sales-scrappage safety model comprised two components.¹⁹⁷⁵ First, the agencies estimated an empirical relationship among vehicle age, model year or vintage, and fatalities using the FARS database of fatal crashes, vehicle registration data from Polk to represent the on-road vehicle population, and the mileage accumulation schedules discussed in Section [cross-cite to VMT] to estimate total vehicle use.¹⁹⁷⁶ These data were used to construct per-mile fatality rates that varied by vehicle vintage, and also accounted for the influence of vehicle age. To accomplish this, the agencies used FARS data at a lower level of resolution; rather than looking at each crash and the specific factors that contributed to its occurrence, the agencies looked at the total number of fatal crashes involving light-duty vehicles over time with a focus on the influence of vehicle *age* and vehicle *vintage*. The model used in the proposal incorporated a weighted quartic polynomial regression (with each observation weighted by the number of registered vehicles it represented) on vehicle age, and included fixed effects for each model year present in the dataset. The model reproduced the observed fatalities of a given model year, at each age, reasonably well with more recent model years estimated with smaller errors. These estimates were used to account for the inherent safety risks of the legacy fleet and the influence of age on a vehicle's fatality rate.

In the proposal, the agencies noted that factors other than the advent of new safety technologies have affected the historical trend in fatality and injury rates and are likely to continue to do so in the future. These include changes in driver behavior, including seat belt use, driving under the influence of alcohol or drugs, and driver distraction, particularly from the use of hand-held electronic devices such as smartphones, all of which affect either the frequency with which drivers are involved in crashes or the severity of accidents. They also include changes in the demographic composition of driving, since drivers of different ages, gender, income levels, and educational attainment have differing accident-involvement rates, as well as in the geographic distribution of motor vehicle travel, since road and driving conditions (visibility, etc.) tend to be poorer in rural areas than in urban locations, thus leading to more frequent and more severe crashes. Other factors affecting safety trends include infrastructure investments and road maintenance practices that improve road design and travel conditions, thus reducing the frequency and severity of crashes, improvements in accident response and emergency medical care, and cyclical variation in economic activity, which affects the demographic composition of drivers on the road.

Seat belts have historically been the single most effective safety technology, preventing roughly half of all fatalities in the event of a potentially fatal crash, and accounting for over half the lives cumulatively

¹⁹⁷⁵ The derivation of the NPRM analysis is discussed in detail in Section 7 of the FRIA.

¹⁹⁷⁶ The analysis supporting the CAFE rule for MYs 2017 and beyond did not account for differences in exposure or inherent safety risk as vehicles aged throughout their useful lives. However, the relationship between vehicle age and fatality risk is an important one. In a 2013 Research Note, NHTSA's National Center for Statistics and Analysis (NCSA) concluded a driver of a vehicle that is 4-7 years old is 10% more likely to be killed in a crash than the driver of a vehicle 0-3 years old, accounting for the other factors related to the crash. This trend continued for older vehicles more generally, with a driver of a vehicle 18 years or older being 71% more likely to be killed in a crash than a driver in a new vehicle. "How Vehicle Age and Model Year Relate to Driver Injury Severity in Fatal Crashes," DOT HS 811 825, NHTSA NCSA, August 2013. While there are more registered vehicles that are 0-3 years old than there are 20 years or older (nearly three times as many) because most of the vehicles in earlier vintages are retired sooner, the average age of vehicles in the United States is 11.6 years old and has risen significantly in the past decade.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

saved by all FMVSS-related safety technologies since 1960.¹⁹⁷⁷ While belts have been in passenger vehicles since the 1960s, few drivers or passengers initially used them. Over the past 3 decades, seat belt usage rates have steadily climbed from under 60 percent in the early 1990s to roughly 90 percent in 2018 and has been the single most significant factor in reducing fatality rates over time. Additional changes in seat belt use are possible but challenging to achieve, since the last drivers to buckle up are typically the most likely to be risk takers and are often the most resistant to changing their habits. Moreover, with usage rates already at 90 percent, there is less potential for continued improvement.

Overall, the agencies believe improvement in seat belt use is unlikely to have the impact going forward that it has in the past. Technological fixes are possible for seat belt use and impaired driving, but would likely require the promulgation of new regulation, and therefore cannot be assumed. Similarly, individual States could take steps to address impaired driving, speeding, driver distraction, seat belt use and roadway infrastructure improvements, but the pace and impact of such improvements is speculative. The agencies also note that improvements in roadway infrastructure and human factors such as belt and alcohol use potentially affect both old and new vehicles alike. If improvements in these non-vehicle factors are equally spread across vehicles of all MY age groups, the differences in their fatality rates would not change. In other words, these types of improvements might shift the entire MY fatality rate curve down rather than change its slope.

Nonetheless, the agencies stated that it was reasonable to expect some continuation in the generalized trend from non-vehicle technology factors such as these. In the analysis supporting the NPRM, our statistical model controlled for non-vehicle safety factors by accounting for the well-documented fact that older vehicles tend to be owned and driven by drivers whose demographic characteristics, behavior, and geographic location tends are associated with more frequent or severe crashes.

Second, the agencies created estimates of future fatality rates. The agencies noted that predicting future safety trends has an inherent degree of uncertainty, which was amplified due to the dearth of academic and empirical research available at the time of the proposal. Although the agencies expected further safety improvements because of advanced driver assistance systems, such as automatic braking and eventually fully automated vehicles, the pace of development and extent of consumer acceptance of these improvements was uncertain. Thus, instead of attempting to model the impact of future safety features directly, the agencies relied on two different trend models to predict future safety trends. The first model relied on the results from a previous NCSA study that measured the effect of known safety regulations on fatality rates by performing statistical evaluations of the effectiveness of motor vehicle safety technologies based on real world performance in the on-road vehicle fleet to determine the effectiveness of each safety technology.¹⁹⁷⁸ The agencies used this information to forecast future fatality rates. The second model employed was simpler. The agencies used actual, aggregate fatality rates measured from 2000 through 2016 and modeled the fatality rate trend based on these historical data.

The agencies noted that both models had significant limitations and predicted significantly different safety trends. The NCSA study focused on projections to reflect known technology adaptation requirements, but it was conducted prior to the 2008 recession, which disrupted the economy and changed travel patterns

¹⁹⁷⁸ Blincoc, L. and Shankar, U., “The Impact of Safety Standards and Behavioral Trends on Motor Vehicle Fatality Rates,” National Highway Traffic Safety Administration, DOT HS 810 777, Washington, D.C., January, 2007.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

throughout the country, and predated the emergence of newer technologies in the 2010s. The NCSA anticipated continued improvement well beyond 2020. By contrast, the historical fatality rate model reflected shifts in safety not captured by the NCSA model, but gave arguably implausible results after 2020 because of an observed upward shift in fatalities between 2014 and 2015. It essentially represented a scenario in which economic, market, or behavioral factors minimize or offset much of the potential impact of future safety technology. To reconcile the two projections of safety improvements beyond 2015, the agencies averaged the NCSA and historical fatality rate models, accepting each as an illustration of different and conflicting possible future scenarios.

The agencies received a number of comments on the provisional model used in the NPRM, which focused mainly on its omission of variables that change over time and can affect the safety of all vehicles in use, regardless of their original model year or current age. As indicated previously, these include changes in seat belt use, driving under the influence of alcohol or drugs, use of hand-held electronic devices, driver demographics, the geographic distribution of vehicle use, road design and maintenance, emergency response and medical care, and overall economic activity.

For example, CARB asserted that the NPRM modeling overestimated fatality rates for older vehicles because it did not “control for factors that can have a significant influence on fatality risk, such as crash circumstances and driver characteristics.” Elsewhere, CARB highlighted the omission of calendar year effects from the NPRM analysis, adding “the agencies only model fatality rate as a function of model year, but fatality rate should be a function of both model year and calendar year [...] [which] would account for systematic safety improvements to the entire on-road fleet.”¹⁹⁷⁹ CARB also argued that analysis should account for safety differences between body styles, noting that passenger cars and other LTVs “have historically had different safety regulations.”¹⁹⁸⁰ Passenger cars and LTVs are not always regulated at exactly the same pace and in some circumstances, LTV regulations have differed from passenger car regulations. However, with a few exceptions, both types of passenger vehicles are equipped with safety technologies that address the same basic safety hazards. Historically, these involve regulations that preserve passenger compartment integrity and protect passengers in the event of a crash. These include technologies such as air bags, seat belts, stronger roof structures, side door beams, and fuel tank integrity. Further, going forward, the agencies expect that both vehicle types will eventually all eventually be equipped with the same advanced crash avoidance safety technologies that are currently being developed. Whatever differences there are have influenced the fatality rates and since we use combined average fatality rates (for PCs and LTVs) for the model, the results should closely mirror the results from an analysis that calculates the two vehicle types separately and then adds them together.

Similarly, States and Cities noted the potential importance of factors that can affect trends in vehicle safety over time, pointing out that “increased seat belt use over time, improvements in roadway design and life-saving emergency response and treatment, and crash compatibility with other vehicles improve the overall safety of vehicles currently on the road” and therefore concluded that “the CAFE model’s assumption that the fatality rate of a 1985 model year vehicle is 23.8 per billion vehicle miles traveled for any calendar year is incorrect. That error increases the risk of fatalities determined by the NPRM for scrappage by around

¹⁹⁷⁹ CARB, Detailed Comments, NHTSA-2018-0067-11873 at 263.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

25 percent.”¹⁹⁸¹ Consumers Union echoed this argument and suggested driver characteristics and behavior may “more strongly influence fatality risk than a vehicle’s model year”¹⁹⁸²

IPI speculated that omitting the effect of variables that change over time in ways that could affect fleet-wide safety may have caused the agencies’ analysis to over-emphasize the role of safety improvements to new vehicles. Specifically, IPI observed that “the agencies could not adequately control for driver behavior trends. And a decrease in fatalities could look like it was caused by vehicle improvements over time rather than societal changes.”¹⁹⁸³

The agencies also received a few comments on their modeling choices. For example, CARB commented that the agencies equation for the legacy fleet was “either incorrect or [had] limited domain-of-validity because it can potentially predict negative fatality rates” and because it was missing an intercept term.¹⁹⁸⁴ CARB suggested a logarithmic function would fix the problem. The agencies note that the polynomial specification of the safety model the agencies developed for the legacy fleet was extremely unlikely to predict negative fatality rates in light of the estimated values of its coefficients, and that its fixed-effects specification in effect included separate intercept terms for each model year, with that for the earliest model year serving as the “reference case” and thus performing the normal role of the constant term.

In electing to offset rebound-related safety consequences for the NPRM, the agencies distinguished the rebound effect from mass and fleet turnover impacts by describing the former as a voluntary consumer choice and the latter as imposed by the standards on consumers.¹⁹⁸⁵ The agencies acknowledged in the NPRM that a reasonable argument might be made that consumers’ decisions to purchase newer and safer cars or light trucks and to keep older models in service are also voluntary consumer choices, in which case changes in their decisions in response to newly-adopted CAFE and CO₂ standards might be accompanied by offsetting gains or losses in benefits. The agencies dismissed this argument in the NPRM by noting that new vehicle prices act as a barrier to entry for some consumers, hence—at least “marginal” shoppers—purchasing a more expensive vehicle is *not* a choice; and, without the ability to determine how many potential purchasers are ‘priced out’ of the new vehicle market, it would be inappropriate to offset sales and scrappage safety impacts.¹⁹⁸⁶ The agencies sought comment on this assumption.

The agencies did not receive any suggestions for distinguishing between consumers who voluntarily delayed purchases and those who were forced to delay a purchase due to high vehicle prices. Thus, the problem of deciphering the motives behind delayed purchases still lingers. However, the agencies did receive several comments advocating that the agencies offset fatalities attributable to sales and scrappage as they do for the rebound effect. For example, NCAT commented that “consumer purchases are voluntary and this effect should not be attributed to the standards.”¹⁹⁸⁷ The environmental group coalition commented that miles driven in older vehicles are “a consumer choice, not something the standards compel.”¹⁹⁸⁸ In

comparing the decision to retain and drive older vehicles to the decision to drive new vehicles more, *i.e.* the rebound effect, EDF concluded, “to treat these identical choices in 180 degree different manners is of course manifestly arbitrary.”¹⁹⁸⁹

On a rudimentary level, the agencies agree with commenters that purchasing decisions are a consumer choice. While reducing the stringency of the standards should make new vehicles more affordable, nothing in today’s rule requires consumers to purchase a new vehicle; likewise, the analysis does not assume *every* older vehicle will be replaced immediately. There is no strict requirement that the agencies must offset consumer choices. In fact, such a viewpoint would be untenable. Nothing in today’s rule compels private parties to *do* anything. If the agencies assumed all *freely chosen* or *voluntary* actions, such as *driving* or *manufacturing automobiles*, were not attributable to the rule, then each regulatory scenario would have the same net benefit—zero. As such, the agencies explanation in the proposal of *freely chosen* and *voluntary* was likely imprecise and led commenters to an overly broad conclusion. Deciding which behavioral responses are unambiguously attributable to a regulation and should thus be quantified, and distinguishing them from responses that would be anticipated to occur in its absence is inherently part of the rulemaking process, and inevitably requires agencies considering new regulations to apply careful judgment in making those distinctions.

To that end, the agencies felt it was appropriate to offset rebound-related safety costs because of the benefit rebound miles confer to society. As described in more detail in Section 1.b)(6), additional driving that occurs as a consequence of the fuel economy rebound effect is undertaken *voluntarily*, and we can infer from the fact that it is *freely chosen* that the mobility benefits it provides necessarily exceed the additional operating costs and increased exposure to safety risks it entails. Since reducing the standards has the ancillary effect of reducing rebound miles, the agencies concluded that including safety costs associated with rebound driving would cause the agencies to underestimate the lost value of rebound driving; therefore, it was appropriate to offset rebound safety costs to account for the lost benefits.¹⁹⁹⁰ Thus, the significance of the terms *freely chosen* and *voluntary* was to signal that consumers’ actions were motivated in part by benefits that may not have been not explicitly identified or accounted for, rather than to act as a prohibitive characteristic.

When considering commenters’ suggestion to offset fleet turnover fatalities (as well as injury and ancillary costs), the agencies attempted to identify specific benefits whose loss would be logically attributable to the changes in standards this rule adopts, and were not accounted for elsewhere in their analysis. The agencies considered whether accelerated turnover of the car and light truck fleet could cause mobility losses analogous to those resulting from the rebound effect, but determined that on balance, increasing the pace at which new vehicles replace older models that are retired from use provides additional mobility and other benefits.¹⁹⁹¹ In addition, the agencies considered whether consumers experience some previously unidentified loss in welfare when they purchase new vehicles, particularly when they do so to replace an older model. As explained in in Section 1.b)(6) and 1.b)(8), the agencies instead concluded that

¹⁹⁸⁹ EDF, Appendix B, NHTSA-2018-0067-12108, at 58.

¹⁹⁹⁰ Arguably rebound fatalities and non-fatal injuries should be included in today’s analysis as a cost without an offset. While a perfectly rational driver would fully and accurately internalize the costs associated with driving on a per-mile basis and would only drive if the expected benefits *at least* offset the expected costs, it is difficult to ascertain how much of the risk a real person internalizes. If not for the reduced standards, fatalities *would* increase due to rebound driving.

¹⁹⁹¹ This occurs because newer vehicles are not only more fuel-efficient on average than the older models they replace, but also provide more reliable, comfortable, and otherwise higher-quality transportation service, so they tend to be driven more than those they replace.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

purchasers instead experience gains in welfare as a result, but that the resulting benefits are already accounted for elsewhere in their analysis.

Finally, the agencies contemplated whether—as commenters contended—owners of older vehicles derive some heretofore unaccounted-for benefit from continuing to use them, which might be reduced when the rule encourages more rapid retirement of older models. Applying the same logic used to explain additional driving in response to the rebound effect, an older vehicle will continue to be maintained in working condition and driven when the benefits provided to the owner is sufficient to offset the costs of maintenance and operation, including the economic costs associated with additional exposure to safety risks. Therefore, there *is* a benefit to driving an older vehicle. But the relevant question is not whether a benefit exists whether and how this rule might affect those benefits. With the very limited exception of classic cars, it is unlikely that the benefit of driving an older vehicle confers a greater benefit than driving a newer vehicle.¹⁹⁹² Normally, when a vehicle is scrapped, it is replaced with a newer vehicle. Hence mobility is not lost, but rather transferred between vehicles—and with it, the associated benefits.¹⁹⁹³ In the limited instances where a retired vehicle is not replaced with a newer vehicle, that action is freely taken and the agencies can infer from that decision that the benefit derived from scrapping the vehicle outweighed any possible loss, including lost mobility. Offsetting the reduction in scrappage safety costs—realized because of the standards—without a complementary benefit would be directionally inconsistent.¹⁹⁹⁴

The agencies reaffirm that off-setting safety costs attributable to the sales and scrappage effects is inappropriate. Commenters' arguments relied exclusively on the premise that driving older vehicles is freely chosen and thus must have associated benefits, without considering the impact of accelerating their retirement on the rule's overall net safety and mobility benefits. Furthermore, the agencies remain concerned that potential buyers may be “frozen out” of the new vehicle market by prohibitively high prices; in which case enabling access to newer, safer vehicles provides measurable safety benefits that should be considered by the analysis.

However, in an abundance of caution, the agencies performed a sensitivity analysis that applies the same safety offset to sales/scrappage safety impacts that was applied to the rebound effect safety impacts. The results are provided in [Table II-137](#)~~Table VI-208~~ below. As might be expected, this adjustment reduces net benefits in all scenarios, but does not substantially shift the relative scope among alternatives.

¹⁹⁹² If the benefit of driving an older vehicle was higher than the benefit of driving a newer vehicle, we would anticipate consumers to forgo replacing older vehicles with newer vehicles.

¹⁹⁹³ Since driving newer vehicles, including newer used vehicles, likely confers greater benefits than would-be scrapped vehicle, the agencies are likely *underestimating* the value of increased scrappage.

¹⁹⁹⁴ A similar argument could be made that consumers ‘internalize’ additional fuel costs, and therefore pre-tax fuel savings should also be offset. However, this would also ignore that benefits are remaining constant while the costs to obtain those benefits is increasing.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***
Table II-~~137240~~ - Impact of offsetting Sales Scrappage Safety Benefits on Net Benefits

	1	2	3	4	5	6	7
Model Years	2021-2026	2021-2026	2021-2026	2021-2026	2022-2026	2021-2026	2022-2026
Annual Rate of Stringency Increase	0.0%/Year PC 0.0%/Year LT	0.5%/Year PC 0.5%/Year LT	1.5%/Year PC 1.5%/Year LT	1.0%/Year PC 2.0%/Year LT	1.0%/Year PC 2.0%/Year LT	2.0%/Year PC 3.0%/Year LT	2.0%/Year PC 3.0%/Year LT
Total Safety Impacts MY 1977-2029, 3% Discount Rate, CAFE							
Central Analysis	-16.3	-16	-13.1	-8.7	-1.4	0.8	0.3
Offsetting Sales Scrappage Safety	-29.1	-28.4	-23.2	-18.4	-8.4	-5.9	-4.1
Total Safety Impacts MY 1977-2029, 7% Discount Rate, CAFE							
Central Analysis	18.4	18	16.1	18.1	16.6	17.7	12.7
Offsetting Sales Scrappage Safety	8.3	8.1	7.8	10.1	10.8	12.0	8.8
Total Safety Impacts MY 1977-2029, 3% Discount Rate, CO ₂							
Central Analysis	-31.1	-29.7	-22	-20.9	-12.9	-13.8	-7.9
Offsetting Sales Scrappage Safety	-42.0	-40.3	-31.1	-29.6	-19.4	-19.9	-12.4
Total Safety Impacts MY 1977-2029, 7% Discount Rate, CO ₂							
Central Analysis	4.6	4.8	6.4	6.3	6.1	5.9	4.4
Offsetting Sales Scrappage Safety	-3.6	-3.1	-0.6	-0.4	1.1	1.0	0.9

Again, the agencies feel that this offset is inappropriate. The sensitivity case disregards many of the tangible gains in safety expected from increased sales and scrappage. Furthermore, the agencies note that—even if they replaced the central analysis’ assumptions with this sensitivity case—the anticipated changes in net benefits would not be enough to change their decision.

(2) *Revised Sales-Scrappage Safety Model*

In response to the comments, the agencies have taken several steps to revise the sales-scrappage safety model. First, the agencies developed a revised statistical model to explain historical improvements in the lifetime safety performance of each successive new vintage of cars and light trucks, and used the results of this improved model to project the future trend in the overall fatality rates. While the revised historical trend model itself is more complex than the one utilized in the proposal, the overall procedure is simpler; the agencies have collapsed the two piecemeal components discussed above into one model and eliminated the need to ‘reconcile’ differences between competing future projections. Next, the agencies applied detailed empirical estimates of the market uptake and improving effectiveness of crash avoidance technologies to estimate their effect on the fleet-wide fatality rate, including explicitly incorporating both the direct effect of those technologies on the crash involvement rates of new vehicles equipped with them, as well as the “spillover” effect of those technologies on improving the safety of occupants of vehicles that are not equipped with these technologies.

(a) *Crash Avoidance*

In the NPRM, the agencies took a very generalized approach to estimating the pace of future safety trends. For reasons discussed above, the agencies noted that there was uncertainty regarding actual trends in fatality rates. This issue was addressed by numerous commenters who took opposing positions. Among them, IPI stated that “[t]he agencies have not provided an adequate explanation for why past safety trends are likely to continue until the mid-2020s.” IPI further noted that “crash avoidance technology may not be adopted as easily or readily as crash mitigation technologies have been.”¹⁹⁹⁵ In response, the agencies note that the trend the agencies adopted for the NPRM was not a direct continuation of past trends. Rather, it was a simple average of several possible models the agencies had examined, accepting each as an illustration of different and conflicting possible future scenarios.

By contrast, States and Cities asserted that fatality rates may be lower in the future than the agencies estimated, noting that the NPRM analysis did not “account for safety benefits that new safety technologies in future vehicles will have on the agencies predicted outcome.”¹⁹⁹⁶ While the agencies agree that the NPRM analysis did not analyze individual safety benefits of new technologies, the trends included in the NPRM were intended, in part, as a proxy estimate of the impact of these technologies. As discussed in the NPRM, these technologies were cited as a justification for assuming a continued downward trend in the fatality rate through roughly 2035.

¹⁹⁹⁵ IPI, Appendix, NHTSA-2018-0067-12213, at 98.

¹⁹⁹⁶ States and Cities, Detailed Comments, NHTSA-2018-0067-11735, at 80.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Nonetheless, the agencies believe that further analysis of these potential trends can now be ascertained for several explicit technologies. In response to comments suggesting that the agencies account more directly for new safety technologies, the agencies augmented the sales-scrappage safety analysis for the final rule with recent research into the effectiveness of specific advanced crash avoidance safety technologies (also known as ADAS or advanced driver assistance systems) that are expected to drive future safety improvement to estimate the impacts of crash avoidance technologies. The analysis analyzes six crash avoidance technologies that are currently being produced and commercially deployed in the new vehicle fleet. These include Frontal Collision Warning (FCW), Automatic Emergency Braking (AEB), Lane Departure Warning (LDW), Lane Keep Assist (LKA), Blind Spot Detection (BSD), and Lane Change Alert (LCA).¹⁹⁹⁷ These are the principal technologies that are being developed and adopted in new vehicle fleets and will likely drive vehicle-based safety improvements for the coming decade. These technologies are being installed in more and more new vehicles; in fact, 12 manufacturers recently reported that they voluntarily installed AEB systems in more than 75 percent of their new vehicles sold in the year ending August 31, 2019.¹⁹⁹⁸ The agencies note that the terminology and the detailed characteristics of these systems may differ across manufacturers, but the basic system functions are common across all.

These 6 technologies address three basic crash scenarios through warnings to the driver or alternately, through dynamic vehicle control:

1. Forward collisions, typically involving a crash into the rear of a stopped vehicle;
2. Lane departure crashes, typically involving inadvertent drifting across or into another traffic lane; and
3. Blind spot crashes, typically involving intentional lane changes into unseen vehicles driving in or approaching the driver's blind spot.

Unlike traditional safety features where the bulk of the safety improvements were attributable to improved protection when a crash occurs (crash worthiness), the impact of advanced crash avoidance technologies (ADAS or advanced driver assistance systems) will have on fatality and injury rates is a direct function of their effectiveness in preventing or reducing the severity of the crashes they are designed to mitigate. This effectiveness is typically measured using real world data comparing vehicles with these technologies to similar vehicles without them. While these technologies are actively being deployed in new vehicles, their penetration in the larger on-road vehicle fleet has been at a low, but growing level. This limits the precision of statistical regression analyses, at least until the technologies become more common in the on-road fleet.

Our approach in the final rule is to derive effectiveness rates for these advanced crash-avoidance technologies from safety technology literature. The agencies then apply these effectiveness rates to specific crash target populations for which the crash avoidance technology is designed to mitigate and adjusted to reflect the current pace of adoption of the technology, including the public commitment by manufactures to install these technologies. The products of these factors, combined across all 6 advanced technologies, produce a fatality rate reduction percentage that is applied to the fatality rate trend model discussed below,

¹⁹⁹⁷ A full description of these technologies and several other technologies referenced below may be found in the corresponding FRIA safety impacts discussion

¹⁹⁹⁸ NHTSA Announces Update to Historic AEB Commitment by 20 Automakers, NHTSA press release December 17, 2019. <https://www.nhtsa.gov/press-releases/nhtsa-announces-update-historic-aeb-commitment-20-automakers>

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

which projects both vehicle and non-vehicle safety trends. The combined model produces a projection of impacts of changes in vehicle safety technology as well as behavioral and infrastructural trends.

(i) Technology Effectiveness Rates

Forward Crash Collision Technologies

For forward collisions, manufacturers are currently equipping vehicles with FCW, which warns drivers of impending collisions, as well as AEB, which incorporates the sensor systems from FCW together with dynamic brake support (DBS) and crash imminent braking (CIB) to help avoid crashes or mitigate their severity. Manufacturers have committed voluntarily to install some form of AEB on all light vehicles by the 2023 model year (September 2022).¹⁹⁹⁹

Table II-138 Table I-1 summarizes studies which have measured effectiveness for various forms of FCW and AEB over the past 13 years. Most studies focused on crash reduction rather than injury reduction. This is a function of limited injury data in the on-road fleet, especially during the early years of deployment of these technologies. In addition, it reflects engineering limitations in the technologies themselves. Initial designs of AEB systems were basically incapable of detecting stationary objects at speeds higher than 30 mph, making them potentially ineffective in higher speed crashes that are more likely to result in fatalities or serious injury. For example, Wiacek et al. (2-15) conducted a review of rear-end crashes involving a fatal occupant in the 2003-2012 NASS-CDS data-bases to determine the factors that contribute to fatal rear-end crashes.²⁰⁰⁰ They found that the speed of the striking vehicle was the primary factor in 71 percent of the cases they examined. The average Delta-V of the striking vehicle in these cases was 46 km/h (28.5 mph), implying pre-crash travel speeds in excess of this speed. While Table II-138 Table I-1 includes studies going back to 2005, the agencies focus our discussion on more recent studies conducted after 2012 in order to reflect more current safety systems and vehicle designs.

Doecke et al. (2012) created simulations of 103 real world crashes and applied AEB system models with differing specifications to determine the change in impact speed that various AEB interventions might produce. Their modeling found significant rear-end crash speed reductions with various AEB performance assumptions. In addition, they estimated a 29 percent reduction in rear-end crashes and that 25 percent of crashes over 10 km/h were reduced to 10 km/h or less.

Cicchino (2016) analyzed the effectiveness of a variety of forward collision mitigation systems including both FCW and AEB systems. Cicchino used a Poisson regression to compare rates of police-reported crashes per insured vehicle year between vehicles with these systems and the same models that did not elect to install them. The analysis was based on crashes occurring during 2010 to 2014 in 22 States and controlled for other factors that affected crash risk. Cicchino found that FCW reduced all rear-end striking crashes by 27 percent and rear-end striking injury crashes by 20 percent, and that AEB functional at high-speeds reduced these crashes by 50 and 56 percent, respectively. She also found that low speed AEB without driver warning reduced all crashes by 43 percent and injury crashes by 45 percent. She also found that even low-speed AEB could impact crashes at higher speed limits. Reductions were found of 53 percent, 59 percent, and 58 percent for all rear-end striking crash rates, rear-end striking injury crash rates, and rear-end third party injury crash rates, respectively, at speed limits of 40-45 mph. For speed limits of 35 mph or less, reductions of 40 percent, 40 percent, and 43 percent were found. For speed limits of 50 mph or greater, reductions of 31 percent, 30 percent, and 28 percent, were found. Further, Cicchino (2016) found significant reductions (30 percent) in rear-end injury crashes even in crashes on roadways where speed limits exceeded 50 mph.

Kusano and Gabler (2012) examined the effectiveness of various levels of forward collision technologies including FCW and AEB based on simulations of 1,396 real world rear end crashes from 1993-2008 NASS CDS data-bases. The authors developed a probability-based framework to account for variable driver responses to the warning systems. Kusano and Gabler found FCW systems could reduce rear-end

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

crashes by 3.2 percent and driver injuries in rear-end crashes by 29 percent. They also found that full AEB systems with FCW, pre-crash brake assist, and autonomous pre-crash braking could reduce rear-end crashes by 7.7 percent and reduce moderate to fatal driver injuries in rear-end crashes by 50 percent.

Fildes et al. (2015) performed meta-analyses to evaluate the effectiveness of low-speed AEB technology in passenger vehicles based on real-world crash experience across six different predominantly European countries. Data from these countries was pooled into a standard analysis format and induced exposure methods were used to control for extraneous effects. The study found a 38 percent overall reduction in rear-end crashes for vehicles with AEB compared to similar vehicles without this technology. The study also found no statistical evidence for any difference in effectiveness between urban roads with speed limits less than or equal to 60 km/h, and rural roads with speed limits greater than 60 km/h. Fildes et al. (2015) found no statistical difference in the performance of AEBs on lower speed urban or higher speed rural roadways.

Kusano and Gabler (2015) simulated rear-end crashes based on a sample of 1,042 crashes in the 2012 NASS-CDS. Modelling was based on 54 model year 2010-2014 vehicles that were evaluated in NHTSA's New Car Assessment Program (NCAP). Kusano and Gabler found FCW systems could prevent 0-67 percent of rear-end crashes and 2-69 percent of serious to fatal driver injuries.

Leslie et al (2019) analyzed the relative crash performance of 123,377 General Motors (GM) MY 2013 to 2017 vehicles linked to State police-reported crashes by Vehicle Identification numbers (VIN). GM provided VIN-linked safety content information for these vehicles to enable precise identification of safety technology content. The authors analyzed the effectiveness of a variety of crash avoidance technologies including both FCW and AEB separately. They estimated effectiveness comparing system-relevant crashes to baseline (control group) crashes using a quasi-induced exposure method in which rear-end struck crashes are used as the control group. Leslie et al found that FCW reduced rear-end striking crashes of all severities by 21 percent, and that AEB (which includes FCW) reduced these crashes by 46 percent.²⁰¹⁵

For this analysis, the agencies based their projections on Leslie et al because they are the most recent study, and thus reflect the most current versions of these systems in the largest number of vehicles, and also because they arguably have the most precise identification of the presence of the specific technologies in the vehicle fleet. Furthermore, Leslie et al. was the only study to report estimates for each of the six crash avoidance technologies analyzed for the final rule, hence providing a certain level of consistency amongst estimates. The agencies recognize that there is uncertainty in estimates of these technologies effectiveness, especially at this early stage of deployment. For this reason, the agencies examine a range of effectiveness rates to estimate boundary outcomes in a sensitivity analysis.

²⁰¹⁵ The agencies note that UMTRI, the sponsoring organization for the Leslie et al study, published a previous version of this same study utilizing the same methods in March of 2018 (Flannagan, C. and Leslie, A, Crash Avoidance Technology Evaluation Using real-World crashes, University of Michigan Transportation research Institute, March 22, 2018). The agencies focused on the more recent 2019 study because its sample size is significantly larger and it represents more recent model year vehicles. The revised (2019) study uses the same basic techniques but incorporated a larger data-base of system-relevant and control cases (123,377 cases in the 2019 study vs. 35,401 in the 2018 study). Relative to the Flannagan and Leslie (2018) findings, the results of the 2019 study varied by technology. The revised study found effectiveness rates of 21% for FCW and 46% for AEB, compared to 16% and 45% in the 2018 study. The revised study found effectiveness rates of 10% for LDW and 20% for LKA, compared to 3% and 30% for these technologies in the 2018 study. The revised study found effectiveness rates of 3% for BSD and 26-37% for LCA systems, compared to 8% and 19-32% for these technologies in the 2018 study. Thus, some system effectiveness estimates increased while others decreased.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Leslie et al. measured effectiveness against all categories of crashes, but did not specify effectiveness against crashes that result in fatalities or injuries. The agencies examined a range of effectiveness rates against fatal crashes using a central case based on boundary assumptions of no effectiveness and full effectiveness across all crash types. Our central case is thus a simple average of these two extremes. Sensitivity cases were based on the 95th percent confidence intervals calculated from this central case. Leslie et al found effectiveness rates of 21 percent for FCW and 46 percent for AEB. Our central fatality effectiveness estimates will thus be 10.5 percent for FCW and 23 percent for AEB. The calculated 95th percentile confidence limits range is 8.11 to 12.58 percent effective for FCW and 20.85 to 25.27 for AEB. The agencies note that our central estimate is conservative compared to averages of those studies that did specifically examine fatality impacts; that is, the analysis assumes reduced future fatalities less than most of, or the average of, those studies, and thus minimizes the estimate of lives saved under alternatives to the augural standards. Furthermore, the agencies note that the estimates against fatal crashes is higher in the recent studies in Table II-2, which reflects the agencies' understanding that earlier iterations of AEB and FCW may have been less effective against crashes that result in fatalities than newer and improved versions.²⁰¹⁶

Lane Departure Crash Technologies

For lane departure crashes, manufacturers are currently equipping vehicles with lane departure warning (LDW), which monitors lane markings on the road and alerts the driver when their vehicle is about to drift beyond a delineated edge line of their current travel lane, as well as lane keep assist (LKA), which provides gentle steering adjustments to help drivers avoid unintentional lane crossing.

Table II-139Table I-3 summarizes studies which have measured effectiveness for LDW and LKA

Table II-139212 - Summary of LDW Technology Effectiveness Estimates

Authors	LDW Type	Crash Reduction	Fatalities	Injury Reduction	
				Serious	All Injuries
Cicchino (2018) ²⁰¹⁷	LDW	11%			
Sternlund, Strandroth, et al (2017) ²⁰¹⁸	LDW/LKA				6-30%
Leslie et al. (2019) ²⁰¹⁹	LDW	10%			
	LKA	20%			

²⁰¹⁶ As an example of improvements, the agencies note that the Mercedes system described in their 2015 owner's manual specified that for stationary objects the system would only work in crashes below 31 mph, but that in their manual for the 2019 model, the systems are specified to work in these crashes up to 50 mph.

Authors	LDW Type	Crash Reduction	Fatalities	Injury Reduction	
				Serious	All Injuries
Kusano & Gabler (2015) ²⁰²⁰	LDW	11-23%	13-22%	13-22%	
Kusano, Gorman, et al (2014) ²⁰²¹	LDW	29%		24%	

Cicchino (2018) examined crash involvement rates per insured vehicle year for vehicles that offered LDW as an option and compared crash rates for those that had the option installed to those that did not. The study focused on single-vehicle, sideswipe, and head-on crashes as the relevant target population for LDW effectiveness rates. The study examined 5,433 relevant crashes of all severities found in 2009-2015 police-reported data from 25 States. The study was limited to crashes on roadways with 40 mph or greater speed limits not covered in ice or snow since lower travel speeds would be more likely to fall outside of the LDW systems' minimum operational threshold. Cicchino found an overall reduction in relevant crashes of 11 percent for vehicles that were equipped with LDW. She also found a 21 percent reduction in injury crashes. The result for all crashes was statistically significant, while that for injury crashes approached significance ($p < 0.07$). Cicchino did not separately analyze LKA systems.

Sternlund et al. (2017) studied single vehicle and head-on injury crash involvements relevant to LDW and LKA in Volvos on Swedish roadways. They used rear-end crashes as a control and compared the ratio of these two crash groups in vehicles that had elected to install LDW or LKA to the ratio in vehicles that did not have this content. Studied crashes were limited to roadways with speeds of 70-120 kph and not covered with ice or snow. Sternlund et al. found that LDW/LKA systems reduced single vehicle and head-on injury crashes in their crash population by 53 percent, with a lower limit of 11 percent, which they determined corresponded to a reduction of 30 percent (lower limit of 6 percent) across all speed limits and road surface assumptions.

Leslie et al (2019) analyzed the relative crash performance of 123,377 General Motors (GM) MY 2013 to 2017 vehicles linked to state police-reported crashes by Vehicle Identification numbers (VIN). GM provided VIN-linked safety content information for these vehicles to enable precise identification of safety technology content. The authors analyzed the effectiveness of a variety of crash avoidance technologies including both LDW and LKA separately. They estimated effectiveness comparing system-relevant crashes to baseline (control group) crashes using a quasi-induced exposure method in which rear-end struck crashes are used as the control group. Leslie et al found that LDW reduced lane departure crashes of all severities by 10 percent, and that LKA (which includes LDW) reduced these crashes by 20 percent.

Kusano et al (2014) developed a comprehensive crash and injury simulation model to estimate the potential safety impacts of LDW. The model simulated results from 481 single-vehicle collisions documented in the NASS-CDS data-base for the year 2012. Each crash was simulated as it actually occurred and again as it would occur had the vehicles been equipped with LDW. Crashes were simulated multiple times to account for variation in driver reaction, roadway, and vehicle conditions. Kusano et al found that

²⁰²⁰ Kusano & Gable, *supra* note 200723.

²⁰²¹ Kusano, K., Gorman, T.I., Sherony, R., and Gabler, H.C. Potential occupant injury reduction in the U.S. vehicle fleet for lane departure warning-equipped vehicles in single-vehicle crashes. *Traffic Injury Prevention* 2014 Suppl 1:S157-64.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

LDW could reduce all roadway departure crashes caused by the driver drifting from his or her lane by 28.9 percent, resulting in 24.3 percent fewer serious injuries.

Kusano and Gabler (2015), simulated single-vehicle roadway departure crashes based on a sample of 478 crashes in the 2012 NASS-CDS. Modelling was based on 54 model year 2010-2014 vehicles that were evaluated in NHTSA's New Car Assessment Program (NCAP). Kusano and Gabler found LDW systems could prevent 11-23 percent of drift-out-of-lane crashes and 13-22 percent of serious to fatally injured drivers.

As noted previously for frontal crash technologies, the agencies will base our projections on Leslie et al because they are the most recent study, thereby reflecting the most current versions of these systems in the largest number of vehicles, and because they arguably have the most precise identification of the presence of the specific technologies in the vehicle fleet. However, unlike forward crash technologies, lane change technologies are operational at travel speeds where fatalities are likely to occur. Both LDW and LKA typically operate at speeds above roughly 35 mph. For this reason, and because the research noted in

Table II-139Table I-3 indicates similar effectiveness against fatalities, injuries, and crashes, the agencies believe it is reasonable to assume the Leslie et al crash reduction estimates are generally applicable to all crash severities, including fatal crashes. Our central effectiveness estimates are thus 10 percent for LDW and 20 percent for LKA. For sensitivity analysis, the agencies adopt the 95 percent confidence intervals from Flannagan & Leslie. For LKA this range is 14.95-25.15 percent. For LDW, the upper range was 4.95-13.93 percent.

Blind Spot Crash Technologies

To address blind spot crashes, manufacturers are currently equipping vehicles with BSD, which detects vehicles in either of the adjacent lanes that may not be apparent to the driver. The system warns the driver of an approaching vehicle's presence to help facilitate safe lane changes and avoid crashes. A more advanced version of this, LCA, also detects vehicles that are rapidly approaching the driver's blind spot.

Table II-140Table I-4 summarizes studies which have measured effectiveness for BSD and LCA.

Table II-140243 - Summary of BSD Technology Effectiveness Estimates

Authors	BSD Type	Crash Reduction	Fatalities	Injury Reduction	
				Serious	All Injuries
Cicchino (2017b) ²⁰²²	BSD	14%			23%
Leslie et al (2019) ²⁰²³	BSD	3%			
	LCA	26%			

²⁰²² Cicchino, J.B. (2017b). Effects of blind spot monitoring systems on police-reported lane-change crashes. Insurance Institute for Highway Safety, August 2017.

²⁰²³ Leslie et al., *supra* note 201430.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Isaksson-Hellman & Lindman (2018) ²⁰²⁴	LCA	30%*			31%**
* reduction in claim costs across all lane change crashes					
** reduction in severe crashes with repair costs greater than \$1250					

Cicchino (2017) used Poisson regression to compare crash involvement rates per insured vehicle year in police-reported lane-change crashes in 26 U.S. States during 2009-2015 between vehicles with blind spot monitoring and the same vehicle models without the optional system, controlling for other factors that can affect crash risk. Systems designs across the 10 different manufacturers included in the study varied regarding the extent to which the size of the adjacent lane zone that they covered exceeded the blind spot area, speed differentials at which vehicles could be detected, and their ability to detect rapidly approaching vehicles, but these different systems were not examined separately. The study examined 4,620 lane change crashes, including 568 injury crashes. Cicchino found an overall reduction of 14 percent in blind spot related crashes of all severities, with a non-significant 23 percent reduction in injury crashes.

Leslie et al (2019) analyzed the relative crash performance of 123,377 2013-2017 General Motors (GM) vehicles linked to State police-reported crashes by Vehicle Identification numbers (VIN). GM provided VIN-linked safety content information for these vehicles to enable precise identification of safety technology content. The authors analyzed the effectiveness of a variety of crash avoidance technologies including both BSD and LCA separately. They estimated effectiveness comparing system-relevant crashes to baseline (control group) crashes using a quasi-induced exposure method in which rear-end struck crashes are used as the control group. Flannagan and Leslie found that BSD reduced lane departure crashes of all severities by 3 percent (non-significant), and that LCA (which includes BSD) reduced these crashes by 26 percent.

Isaksson-Hellman and Lindman (2018) evaluated the effect of the Volvo Blind Spot Information System (BLIS) on lane change crashes. Volvo's BLIS functions as an LCA, detecting vehicles approaching the blind spot as well as those already in it. The authors analyzed crash rate differences in lane change situations for cars with and without the BLIS system based on a population of 380,000 insured vehicle years. The authors found the BLIS system did not significantly reduce the overall number of lane change crashes of all severities, but they did find a significant 31 percent reduction in crashes with a repair cost exceeding \$1250, and a 30 percent lower claim cost across all lane change crashes, indicating a reduced crash severity effect.

Like lane change technologies, blind spot technologies are operational at travel speeds where fatalities are likely to occur. The agencies therefore assume the Leslie et al crash reduction estimates are generally applicable to all crash severities, including fatal crashes. Our central effectiveness estimates are thus 3 percent for BSD and 26 percent for LCA. For sensitivity analysis, the agencies adopt the 95 percent confidence intervals from Flannagan & Leslie. For LCA this range is 16.59-33.74 percent. For BSD, the upper range was 14.72 percent, but the findings were not statistically significant. The agencies therefore limit the range to 0-14.72 percent.

LKA	-0.2258	0.0326	20	14.95	25.15	20	14.95	25.15
BSD	-0.0297	0.0661	3	-10.50	14.72	3	0.00	14.72
LCA	-0.2965	0.0587	26	16.59	33.74	26	16.59	33.74

(ii) Target Populations for Crash Avoidance Technologies

The impact on fatality rates that will occur due to these technologies will be a function of both their effectiveness rate and the portion of occupant fatalities that occur under circumstances that are relevant to the technologies function. The agencies base our target population estimates on a recent study that examined these portions specifically for a variety of crash avoidance technologies including those analyzed here. Wang (2019) documented target populations for five groups of collision avoidance technologies in passenger vehicles including forward collisions, lane keeping, blind zone detection, forward pedestrian impact, and backing collision avoidance. The first three of these affect the light occupant target population examined in this analysis. Wang separately examined crash populations stratified by severity including fatal injuries, non-fatal injuries, and property damaged only (PDO) vehicles. She based her analysis on 2011-2015 data from NHTSA’s Fatality Analysis Reporting System (FARS), National Automotive Sampling System (NASS), and General Estimates System (GES). FARS data was the basis for fatal crashes while nonfatal injuries and PDOs were derived from the NASS and GES.

Wang followed the pre-crash typology concept initially developed by the Volpe National Transportation Systems Center (Volpe). Under this concept, crashes are categorized into mutually exclusive and distinct scenarios based on vehicle movements and critical events occurring just prior to the crash. [Table II-142](#)~~Table I-65~~ summarizes the portion of total annual crashes and injuries for each crash severity category that is relevant to the three crash scenarios examined.

Table II-~~142245~~ - Summary of Target Crash Proportions by Technology Group

Safety System Crash Type	Crashes	Fatalities	MAIS 1-5 Injuries	PDOVs
Frontal Crashes	29.4%	3.8%	31.5%	36.3%
Lane Departure Crashes	19.4%	44.3%	17.1%	11.9%
Blind Spot Crashes	8.7%	1.6%	6.7%	11.8%

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The relevant proportions vary significantly depending on the severity of the crash. The rear-end crashes that are addressed by FCW and AEB technologies tend to be low-speed crashes and thus account for a larger portion of non-fatal injury and PDO crashes than for fatalities. Only 4 percent of fatal crashes occur in front-to-rear crashes, but over 30 percent of nonfatal crashes are this type. By contrast, fatal crashes are highly likely to involve inadvertent lane departure, 44 percent of all light vehicle occupant fatalities occur in crashes that involve lane departure, but only 17 percent of non-fatal injuries and 12 percent of PDOs involve this crash scenario. Blind spot crashes account for only about 2 percent of fatalities, 7 percent of MAIS1-5 injuries, and 12 percent of PDOs.

The target population of this analysis is occupants of the light vehicles subject to CAFE. The values in [Table II-142](#)~~Table I-65~~ are portions of all crashes that occur annually. These include crashes of motor vehicles not subject to the current CAFE rulemaking such as medium and large trucks, buses, motorcycles, bicycles, etc. To adjust for this, the values in Wang were normalized to represent their portion of all light passenger vehicle (PV) crashes, rather than all crashes of any type. Wang provides total PV fatalities consistent with her technology numbers which are used as a baseline for this process. Based on 2011-2015 FARS data, Wang found an average of 29,170 PV occupant fatalities occurred annually.

A second adjustment to Wang's results was made to make them compatible with the effectiveness estimates found in Leslie et al. In her target population estimate for lane departure warning, Wang included both head-on collisions and rollovers, but Leslie et al did not. The Leslie et al effectiveness rate is thus applicable to a smaller target population than that examined by Wang. To make these numbers more compatible, counts for these crash types were removed from Wang's lane departure totals.

Electronic Stability Control (ESC) has been standard equipment in all light vehicles in the US since the 2012 model year. ESC is highly effective in reducing roadway departure and traction loss crashes, and although it will be present in all future model year vehicles, it was present in only about 30 percent of the 2011-2015 on-road fleet examined by Wang. To reflect the impact of ESC on future on-road fleets therefore, the agencies further adjusted Wang's numbers to reflect a 100 percent ESC presence in the on-road fleet. The agencies allocated the reduced roadway departure fatalities to the LDW target population, and the reduced traction loss fatalities to the AEB target population. This has the effect of reducing the total fatalities in both groups as well as in the total projected fatalities baseline.

[Table II-143](#)~~Table I-76~~ summarizes the revised incidence counts and re-calculated proportions of total PV occupant crash /injury. Revised totals are derived from original totals referenced in Table 1-3 in Wang (2019).

Table II-~~143~~~~216~~ - Adjusted Target Crash Counts and Proportions

Crash Type	Crashes	Fatalities	MAIS 1-5	PDOVs
Frontal Crashes	1,703,541	1,048	883,386	2,641,884
% All PV Occupant Crashes	30.2%	4.0%	32.4%	36.8%

(iii) Fleet Penetration Schedules

The third element of the rule's safety projections is the fleet technology penetration schedules. Advanced safety technologies (ADAS) will only influence the safety of future MY fleets to the extent that they are installed and used in those fleets. These technologies are already being installed on some vehicles to varying degrees, but the agencies expect that over time, they will become standard equipment due to some combination of market pressure and/or safety regulation. The agencies adopt this assumption based on the history of most previous vehicle safety technologies, which are now standard equipment on all new vehicles sold in the US.

The pace of technology adoption is estimated based on a variety of factors, but the most fundamental is the current pace of adoption in recent years. These published data were obtained from Ward's Automotive Reports for each technology.²⁰²⁵ Since these technologies are relatively recent, only a few years of data—typically 2 or 3 years—were available from which to derive a trend. This makes these projections uncertain, but under these circumstances, a continuation of the known trend is the baseline assumption, which the agencies modify only when there is a rationale to justify it.

The technologies were examined in pairs reflecting their mutual target populations. Both FCW and AEB affect the same target population—frontal collisions. Both systems have been installed in some current MY vehicles, but their relative paces are expected to diverge significantly due to a formal agreement brokered by NHTSA and IIHS involving nearly all auto manufacturers, to have AEB installed in 100 percent of their vehicles by September 2022 (MY 2023).²⁰²⁶ Wards first published installation rates for FCW and AEB for the 2016 model year and as of this analysis the 2017 MY is the latest data they have published. The agencies thus have data indicating that FCW was installed in 17.6 percent of MY 2016 vehicles and 30.5 percent of MY 2017 vehicles. AEB was installed in 12.0 percent of MY 2016 vehicles and 27.0 percent of MY 2017 vehicles. AEB was installed in 12.0 percent of MY 2016 vehicles and 27.0 percent of MY 2017 vehicles. More recent reports submitted by manufacturers to the Federal Register indicate that installation rates accelerated in MY 2018 and 2019 vehicles. Four manufacturers, Tesla, Volvo, Audi, and Mercedes, have already met their voluntary commitment of 100 percent installation 3 years ahead of schedule. During the period September 1, 2018 through August 31, 2019, 12 of the 20 manufacturers equipped more than 75 percent of their new passenger vehicles with AEB, and overall manufacturers equipped more than 9.5 million new passenger vehicles with AEB.²⁰²⁷

Because of the NHTSA/IIHS agreement, the agencies assume that AEB will be in 100 percent of light vehicles by the 2023 MY. To derive installation rates for MYs 2018 through 2022, the agencies

²⁰²⁵ Derived from Ward's Automotive Yearbooks, 2014 through 2018, % Factory Installed Electronic ADAS Equipment tables, weighting domestic and imported passenger cars and light trucks by sales volume.

²⁰²⁶ See <https://www.nhtsa.gov/press-releases/nhtsa-iihs-announcement-aeb>.

²⁰²⁷ See NHTSA Announces Update to Historic AEB Commitment by 20 Automakers. December 17, 2019. <https://www.nhtsa.gov/press-releases/nhtsa-announces-update-historic-aeb-commitment-20-automakers>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

interpolate between the MY 2017 rate of 27 percent and the MY 2023 rate of 100 percent. To derive a MY 2015 estimate, the agencies modelled the results for MYs 2016-2023 and calculated a value for year $x=0$, essentially extending the model results back one year on the same trendline.

For FCW, the agencies used the same interpolation/modeling method as was used for AEB to derive an initial baseline trend. However, while both systems are available on some portion of the current MY fleet, the agencies anticipate that by MY 2023, all vehicles will have AEB systems that essentially encompass both FCW and AEB functions. The agencies therefore project a gradual increase in both systems until the sum of both systems penetration rates exceeds 100 percent. At that point, the agencies project a gradual decrease in FCW only installations until FCW only systems are completely replaced by AEB systems in MY 2023.

For LDW, Wards penetration data were available as far back as MY 2013, giving a total of 5 data points through MY 2017. The projection for LDW was derived by modelling these data points. The data indicate a near linear trend and our initial projections of future years were derived directly from this model. Wards did not report any of the more advanced LKA systems until MY 2016, leaving only 2 data points. The agencies modelled a simple trendline through these data points to estimate the pace of future LKA installations. As with Frontal crashes, the agencies assume a gradual phase-in of the most effective technology, LKA, will eventually replace the lesser technology, LDW, and the agencies allow gradual increases in both systems penetration until their sum exceeds 100 percent, at which point LDW penetration begins to decline to zero while LKA penetration climbs to 100 percent.

For blind spot crashes, Wards data was available for MYs 2013-2017 for BSD, but no data was available to distinguish LCA systems. LCA systems were available as optional equipment on at least 10 MY 2016 vehicles.²⁰²⁸ In addition, Flannagan and Leslie found numerous cases in State data-bases involving vehicles with LCA. Because LCA data is not specifically identified, the agencies will estimate its frequency based on the samples found in Flannagan & Leslie. In that study, 62 percent of vehicles with blind spot technologies has BSD alone, while 38 percent had LCA (which includes BSD). The agencies employ this ratio to establish the relative frequency of these technologies in our projections. As with frontal and lane change technologies, the agencies assume a gradual phase-in of the most effective technology, LCA, will eventually replace the lesser technology, BSD, and the agencies allow gradual increases in both systems penetration until their sum exceeds 100 percent, at which point BSD penetration begins to decline to zero while LCA penetration climbs to 100 percent.

Table II-146Table I-109 summarize the resulting estimates of impacts on fatality rates for frontal crash technologies, lane change technologies, and blind spot technologies respectively for MYs 2016-2035. All previously discussed inputs are shown in the tables. The effect of each technology is the product of its effectiveness, it's percent installation in the MY fleet, and the portion of the total light vehicle occupant target population that each technology might address. Since installation rates for each technology apply to different portions of the vehicle fleet (*i.e.*, vehicles have either the more basic or more advanced version of the technology), the effect of the two technologies combined is a simple sum of the two effects. Likewise, since each crash type addresses a unique target population, there is no overlap among the three crash types and the sum of the normalized crash impacts across all three crash types represents the total impact on fatality rates from these 6 technologies for each model year. These cumulative results are shown in the last column of

Table II-146 Table I-109. As technologies phase in to newer MY fleets²⁰²⁹, their impact on the light vehicle occupant fatality rate increases proportionally to roughly 8.5 percent before levelling off. That is, eventually, by approximately MY 2026, these technologies are expected to reduce fatalities and fatality rates for new vehicles by roughly 8.5 percent below their initial baseline levels.

Table II-144 Table I-117 - Phased Impact of Crashworthiness Technologies on Fatality Rates, Forward Collision Crashes

MY	<i>Forward Collision Warning</i>		<i>Automatic Emergency Braking</i>		% T.P.	<i>Weighted Effectiveness</i>
	<i>FCW Eff</i>	<i>% Inst</i>	<i>AEB Eff</i>	<i>% Inst</i>		
2015	10.5%	0.047	23.0%	0.011	4.0%	0.000292
2016	10.5%	0.176	23.0%	0.120	4.0%	0.001831
2017	10.5%	0.305	23.0%	0.270	4.0%	0.00374

2021	10.5%	0.243	23.0%	0.757	4.0%	0.00793
2022	10.5%	0.122	23.0%	0.878	4.0%	0.008534
2023	10.5%	0	23.0%	1	4.0%	0.009139
2024	10.5%	0	23.0%	1	4.0%	0.009139
2025	10.5%	0	23.0%	1	4.0%	0.009139
2026	10.5%	0	23.0%	1	4.0%	0.009139
2027	10.5%	0	23.0%	1	4.0%	0.009139
2028	10.5%	0	23.0%	1	4.0%	0.009139
2029	10.5%	0	23.0%	1	4.0%	0.009139
2030	10.5%	0	23.0%	1	4.0%	0.009139
2031	10.5%	0	23.0%	1	4.0%	0.009139

²⁰²⁹ While it is technically possible to retrofit these systems into the on-road fleet, such retrofits would be significantly more expensive than OEM installations. The agencies thus assume all on-road fleet penetration of these technologies will come through new vehicle sales.

(b) *Fatality Trend Model*

The revised fatality trend model differs from the model employed in the NPRM in four main respects:

- The fatality rates for individual model years and ages were re-calculated to correct the counts of fatalities to occupants of light-duty vehicles and to reflect the revised VMT estimates, the latter of which incorporate revisions to both vehicle registration counts and the estimated relationship between vehicle age and annual use;²⁰³⁰
- In response to comments on the version used in the NPRM, the model adds controls for changes to factors (such as driver demographics and behavior, and geographic patterns of travel) that can affect fatality rates for vehicles of all model years and ages;
- The revised analysis clusters past model years into “safety cohorts,” which are groups of successive model years that exhibit similar fatality rates during their first years of use, in order to represent the actual historical pattern of safety improvements more realistically; and

²⁰³⁰ These revised estimates of the number of miles traveled by vehicles of each model year during past calendar years were developed from the expanded sample of vehicles’ odometer readings obtained by NHTSA.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- The model employs a slightly less complex mathematical relationship between a model year's age and its fatality rate (fatalities per mile driven), which still describes the observed relationship accurately.

Similar to the fatality trend model employed in the proposal, the revised estimates of annual travel were combined with tabulations of annual fatalities occurring among occupants of light-duty vehicles of each model year during past calendar years, tabulated from NHTSA's FARS data. Fatalities occurring in vehicles produced during each model year making up a calendar year's light-duty vehicle fleet are divided by the estimated number of miles they were driven during that calendar year to calculate historical fatality rates by model year and calendar year, measured as fatalities per billion miles traveled. These data represent the dependent variable in the revised statistical model of fatality rates.

Longitudinal or time-series analyses such as the model of historical variation in fatality rates for individual model years need to incorporate three separate effects to account for all potential sources of variation. First, they need to employ model year in some form as an explanatory variable, to account for improvements in the safety of vehicles produced during successive model years that persist throughout their lifetimes in the vehicle fleet. This is an example of a "cohort effect" in the age-period-cohort framework that is widely used to of analysis of population-wide behavior.²⁰³¹ Second, such a model must account for the effect of age on the safety of each individual model year as it grows older, accumulates mileage, and in most cases changes ownership one or more times during its expected service lifetime (the "aging effect" in age-period-cohort analysis).

Finally, most longitudinal analyses, including the historical safety model developed here, need to account explicitly for factors that vary over time—in this case, calendar years. By doing so, they can affect the safety of vehicles of all model years and ages making up the fleet during successive calendar years, or change the composition of total travel by vehicles of different model years and ages. In either case, such time-related factors—often referred to as "period effects"—can change the overall safety performance of the entire fleet from one calendar year to the next, *independently of and in addition to* the changes that would result from the combination of new model years entering the fleet while older ones are retired from service (the cohort effect), and the aging of all model years making up the fleet. For example, an increase in seat belt use among all drivers during a calendar year would be expected to reduce the fatality rates of vehicles of all model years and ages in use during that year, while an economic recession may change the composition of drivers and vehicles on the road during a calendar year. In either case, one result will be a change in the fleet-wide composite fatality rate for that calendar year.

Error! Not a valid bookmark self-reference.

Figure 1-1 below illustrates the contributions of cohort, aging, and time-period effects to changes over time in population-wide behavior. As the figure indicates, these effects are conceptually independent, but interact in ways that combine to produce the observed historical evolution of the fleet-wide fatality rate for light-duty vehicle occupants. Again, calendar year or time-period factors can affect the safety performance

²⁰³¹ For a detailed explanation of the rationale and methods for age-period-cohort analysis, see for example Columbia University Mailman School of Public Health, Population Health Methods: Age-Period-Cohort Analysis, available at <https://www.mailman.columbia.edu/research/population-health-methods/age-period-cohort-analysis> (accessed February 12, 2020); and Kupper, Lawrence L. *et al.*, "Statistical age-period-cohort analysis: A review and critique," *Journal of Chronic Diseases* 38:10 (1985), at 811-830, available at <https://www.sciencedirect.com/science/article/abs/pii/0021968185901055#!> (accessed February 12, 2020).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

of the entire fleet *independently* of the effect that would result from the combination of changes in the specific model years making up the fleet and the advancing ages of all model years, and any “period effect” effect attributable to factors that vary over time is *in addition to* cohort and aging effects.

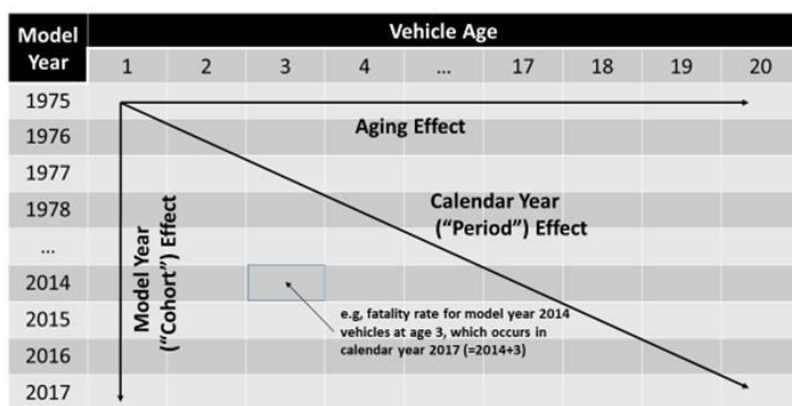

Figure II-4475 - Contributions of Cohort, Aging, and Time-Period Effects to Historical Changes in Fleet-Wide Fatality Rate

To introduce such period effects into the fatality trend model, which were absent from the NPRM analysis, the agencies obtained historical data on factors that varied by calendar year, and were expected to be responsible for such effects. As indicated previously, these included the following:

- Seat belt use, as measured by the fraction of drivers observed to be wearing lap and shoulder belts, estimated by NHTSA’s National Occupant Protection Survey (NOPUS);
- Driving under the influence of alcohol or drugs, measured by the fraction of drivers reporting having recently done so in surveys conducted by the U.S. Centers for Disease Control (CDC);²⁰³²
- Use of hand-held electronic devices, measured by the fraction of drivers visually observed to be doing so in NHTSA’s NOPUS;
- The fraction of licensed drivers who are male and under the age of 25 (historically the riskiest cohort of drivers), as reported by the FHWA’s annual Highway Statistics publication;²⁰³³

²⁰³² The agencies also experimented with measures of drivers appearing to be under the influence of alcohol or drugs included in NHTSA’s NOPUS, available at <https://crashstats.nhtsa.dot.gov/#/PublicationList/18>.

²⁰³³ Federal Highway Administration, Highway Statistics, various years, Table DL-20, available at <https://www.fhwa.dot.gov/policyinformation/statistics.cfm>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- The fraction of miles traveled in rural areas, also as reported by FHWA;²⁰³⁴ and
- The overall performance of the U.S. economy, as measured by the annual rate of unemployment.²⁰³⁵

The agencies were unable to obtain useful measures of roadway design parameters or road conditions that would be expected to affect safety. Although such measures exist, they tend to be reported for individual road and highway segments or routes, and it is difficult to combine these data into meaningful, aggregate measures that describe overall driving conditions that are likely to vary by calendar year. Nor could they identify satisfactory measures of incident response time or the effectiveness of emergency medical treatment in reducing the consequences of injuries occurring in motor vehicle crashes.

An important challenge to incorporating these time-period effects into the fatality trend model arose from the fact that their patterns of variation over the historical period the agencies analyzed (which extended from calendar year 1995 to 2017) were extremely closely correlated, making it virtually impossible to distinguish their independent contributions to improvements in fleet-wide safety over time. [Table II-147](#) below reports the pairwise correlation coefficients among the potential measures of period effects listed above. As it suggests, patterns of variation about their respective mean values over the period analyzed were very similar (with the exception of the unemployment rate), and the resulting high statistical correlations (or “collinearity”) among them made it nearly impossible to identify their independent effects on variation in safety over time, even when controlling for the effects of model year and vehicle age.

Table II-147 - Pairwise Correlation Coefficients Between Period Effect Variables

Variable	Unemployment Rate	% of VMT by Young Males	% of VMT in Rural Areas	% of Occupants Wearing Lap/Shoulder Belts	% of Young Drivers Using Hand-Held Electronic Devices	% of Drivers Consuming Alcohol
Unemployment Rate	1.00	-0.59	-0.54	0.54	0.40	-0.64
% of VMT by Young Males	-0.59	1.00	0.86	-0.98	-0.73	0.95
% of VMT in Rural Areas	-0.54	0.86	1.00	-0.86	-0.86	0.96
% of Occupants Wearing Lap/Shoulder Belts	0.54	-0.98	-0.86	1.00	0.73	-0.93
% of Young Drivers Using Hand-Held Electronic Devices	0.40	-0.73	-0.86	0.73	1.00	-0.80
% of Drivers Consuming Alcohol	-0.64	0.95	0.96	-0.93	-0.80	1.00

To address this difficulty, the agencies substituted a time trend—that is, a variable that takes the value of one in the first calendar year and increases by one in each successive calendar year—in an effort to capture the joint movements in the variables that were intended to measure time-period effects on safety. The agencies experimented with both linear and more complex time trends to capture the apparently declining rate of improvement in fleet-wide safety over time, but found that the linear trend captured the combined effects most reliably. Because the model’s dependent variable is the natural logarithm of model

year and age-specific fatality rates, using a linear time trend corresponds to assuming a constant *percentage* decline in fatality rates each year (rather than a constant absolute decline each year), and this pattern appeared to provide the best fit to the observed historical pattern of safety improvements. Finally, after noting that the linear time trend did not fully capture the effects on fleet-wide safety associated with the economic recessions in 2001 and 2007-11, the agencies supplemented the time trend with indicator (or “dummy”) variables for these years, finding that only those for 2008, 2009, and 2010 improved its explanatory power significantly.

Another significant improvement to the NPRM analysis was to group model years into “safety cohorts” on the basis of similarity in their fatality rates when new (that is, during their first year in service), rather than treating each model year as a separate cohort. Groupings were created through a combination of identifying years when new safety regulations initially took effect or were phased in, examining of first-year fatality rates, and limited statistical experimentation. Grouping successive model years reduces the number of cohorts significantly, since similar fatality rates were typically observed for at least five, and sometimes as many as ten, consecutive model years over the historical period the agencies examined. Grouping model years into a smaller number of cohorts rather than treating each model year as a separate cohort offers the advantage of introducing some variation in the ages of vehicles making up the same cohort during a calendar year, which improves the statistical reliability with which the independent effect of age itself can be estimated.

Figure I-2below shows historical variation in the fatality rates of past model years when each one was newly-introduced (*i.e.*, during its first year in use).²⁰³⁶ It clearly displays the significant improvement in the safety of new vehicles over time in response to improvements in safety features, including those required by NHTSA’s safety regulations. The figure also clearly documents the natural clustering of fatality rates for successive model years that was used to identify and define the safety cohorts used in the revised model. In the panel structure of the model, which combines time-series and cross-section variation in fatality rates for individual model years as their ages vary across calendar years, the clustering of first-year fatality rates for successive model years is captured by using separate “fixed effects” for each safety cohorts illustrated in the figure. Some judgment is inevitably required to distinguish between successive cohorts and identify when the fatality rate for new model years has changed significantly; the agencies experimented with using from five to eight cohorts, ultimately finding that the agencies could distinguish most reliably among the fatality rates for five cohorts.

²⁰³⁶ For simplicity, the figure assumes that each model year’s first year of use was the calendar year identical to its designated model year; for example, the first full year of use for model year 2000 was assumed to be calendar year 2000. In fact, new vehicles frequently become available for purchase during the calendar year preceding their designated model year and continue to be sold through the calendar year following it, although most sales occur during the calendar year matching their designated model year.

Figure II-4576 - Fatality Rates for New Light-Duty Vehicles by Model Year

A final revision to the NPRM model was to employ a slightly less complex mathematical relationship between a model year's age and its fatality rate than had been used in the NPRM version. Specifically, the revised model relates fatality rates to age itself as well as the second and third powers of age (that is, age squared and age cubed), but omits the fourth power of age, which was included in the model developed for the NPRM. This slightly simpler relationship proved adequate to capture fully the complex—but strongly recurring—pattern of fatality rates for past model years as they aged. Specifically, as Figure I-3 below shows, fatality rates have tended to remain approximately constant for the first few years of most recent model years' lifetimes, before increasing steadily through age 15-20 and then declining gradually over the remainder of their lifetimes.

As discussed previously, the increase in fatality rates through approximately age 20 is generally thought to result primarily from the fact that used vehicles are commonly purchased and driven by members of households whose demographic characteristics, driving behavior, and geographic locations are associated with more risky driving behavior and thus more frequent or severe crashes. Of course, increased frequency of mechanical failures as vehicles age and accumulate mileage also seems likely to contribute to this pattern. In contrast, the consistent tendency for fatality rates to decline after about age 20 is less well understood, but may owe partly to the demographic characteristics and driving behavior of owners of very old vehicles. Whatever its source, the number of vehicles remaining in service past age 20 is so small and their use typically so limited that their contribution to the fleet-wide fatality rate is minimal.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Error! Reference source not found. documents the relationship between age and fatality rate for selected past model years.²⁰³⁷ As it shows, fatality rates for recent model years follow a complex but strikingly similar pattern of increase and subsequent decline with increasing age, although the figure also shows that the earliest model years included in the sample (1975-1980) tended not to display increasing fatality rates in the first half of their lifetimes. At the same time, the figure illustrates the gradual downward shift in fatality rates at all ages for successive past model years, although there is considerable variation in the extent of this shift for individual model years, particularly when they are examined at specific ages. That is, the downward shift in fatality rates for successive model years is not necessarily “monotonic,” particularly when it is examined at specific individual ages.

The agencies believe that the increase in fatality rates for cars and light trucks produced during recent model years through approximately age 20 reflects the fact that as aging vehicles change ownership via the used car market, they are often purchased and driven by households whose demographic characteristics and locations are associated with riskier driving behavior and conditions. The decline in vehicles’ fatality rates after this age is not well understood, but seems likely to reflect the fact that the relatively small fraction of those originally produced in a model year that survive beyond age 20-25 are owned and driven by households that maintain them carefully, are likely to reside in areas where driving conditions are safest, and whose members engage in less risky driving behavior. **Error! Reference source not found.**

After examining of the information summarized in Figure I-3, the agencies conclude that the effect of increasing age on vehicle safety appears to be largely independent of the improvement in new cars’ fatality

²⁰³⁷ For a color version, see the corresponding safety discussion in the accompanying FRIA

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

rates over successive model years, and appears to operate similarly for all except the earliest model years in our historical sample (which includes model years 1975-2017).²⁰³⁸ As a formal statistical test, the agencies experimented with allowing the aging effect to change across model years when the agencies estimated the revised model, anticipating that newer safety technologies and vehicle designs might “flatten” the relationship between fatality rates and age—that is, reduce the degree to which fatality rates increased over the 5-20 year range of vehicle ages—for newer model years. However, the agencies found no evidence that the effect of age on safety changed significantly for more recent model years compared to older ones, so the agencies retained the assumption of identical aging effects for all model years in the revised model.²⁰³⁹ Thus the revised model shows progressively lower fatality rates for more recent model years when they are new, but fatality rates for all model years increase with age and subsequently decline according to the same non-linear pattern displayed in Figure I-3.

On a related question, the agencies also found that including the squared and cubed values of age in addition to age itself as explanatory variables in the model, while excluding the fourth power of age, which had been included in the NPRM model, proved adequate to capture the pattern of variation in fatality rates with increasing age that most past model years have exhibited. Table I-12 below reports the estimated parameter values for alternative specifications of the model, together with various goodness-of-fit and other diagnostic measures. The analysis described in the following section uses the estimated time trend from Model 2 in the table, which implies annual reduction in fatality rates for all model years of 2.14 percent.

²⁰³⁸ Of course, the agencies cannot observe the safety performance of all model years included in the agencies’ data sample over their entire lifetimes, because the data the agencies use to estimate the model start in calendar year 1990, by which time all model years before 1990 were no longer new—for example, MY1975 cars are already 15 years old by then—while the newest model years in the agencies’ sample are still very “young” when the agencies’ data ends in calendar year 2017. Thus, the agencies have only incomplete information about the relationship of fatality rates to age over the entire lifetimes of these model years, so it is possible that this relationship differs at particularly early or advanced ages for the oldest and newest model years in the agencies’ sample.

²⁰³⁹ Specifically, the agencies tested for interactions between the age and model year variables, which would reveal changes in the relationship between fatality rates and age for more recent model years, but found that such interaction effects were generally not statistically significant. Allowing for interactions between age and the indicator variables for safety cohorts (recall that these represent groupings of successive model years) produced this same result—few of the interaction effects were statistically significant.

 (c) Using the Model and Technology Analysis to Forecast Fatality Rates

The newest safety cohort includes model years from 2009 to 2017, so in effect the agencies estimate that all those model years have essentially the same fatality rate in their first year of use. The agencies apply the estimated effectiveness of crash avoidance technologies in reducing fatal crashes to the observed fatality rate for model years 2009 to 2017 vehicles during their first year in use to estimate fatality rates for future model years during the first year each one is introduced. [Figure II-46](#) below shows the result of this process; as it indicates, fatality rates for new model years decline gradually through 2035 and then stabilize, reflecting the fact that the agencies are only able to project the effectiveness of emerging crash avoidance technologies on the safety of new vehicles through that year.

Figure II-46 - Fatality Rates for New Cars and Light Trucks by Model Year

The next step in constructing the forecast of fleet-wide fatality rates is to apply the age-related increases in the fatality rate for each model year making up the previous calendar year's fleet. For example, the agencies assume that the fatality rates for all model years comprising the light-duty vehicle fleet in 2017 increase with age according to the relationship captured by the estimated coefficients on the age variables in the preferred model specification shown in Table I-12. The same assumption is applied to all new model years introduced in subsequent years. Finally, the agencies also assume that the historical decline in fatality rates observed over past calendar years (the "period effect" captured by the time trend variable) will continue into the future. This implies that fatality rates for all model years and ages will decline by an additional 2.41 percent in each successive future calendar year from the rates that would have resulted from the combined

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

effects of continuing improvements in the safety of newly-introduced model years and the effect of increasing age.²⁰⁴⁰

This process produces an estimate of the fatality rate for each model year making up the fleet during each future calendar year. That estimate reflects the combination of (1) reductions in fatality rates for new cars, reflecting the continued improvements in their safety due to crash avoidance technologies (through MY2035); (2) increases in the fatality rates for each model year in the fleet from the previous calendar year, which represent the effect of age estimated by the historical model; and (3) the continuing downward trend in fatality rates for all vehicles except the newest model year in each calendar year's fleet, which is derived from the historical model.

The agencies then weight the fatality rate for each model year making up a future year's fleet by the fraction of total fleet-wide VMT it accounts for, and sum the results to produce an estimate of the fleet-wide fatality rate. The CAFE model does not actually use this fleet-wide fatality rate, because all of the fatality calculations are performed separately for each individual model year making up the fleet, which are then aggregated; nevertheless, the agencies provide the fleet-wide rate as a useful check on the reasonableness of our fatality rate forecasts for individual model years as they enter the fleet and age over their respective lifetimes. Figure I-5 displays the projected fleet-wide fatality rates for future calendar years, as well as the trend in their recent historical values.

Figure II-4778 – Historical and Projected Fleet-Wide Fatality Rates

²⁰⁴⁰ The agencies do not apply this trend reduction to the fatality rates for the newest model year in each calendar year's fleet, because it is assumed to be independent of both the decline in new-car fatality rates and the aging effect.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(d) *Impact of Advanced Technologies on Older Vehicle Fatality Rates*

In the NPRM, the agencies calculated the potential safety impacts of delayed purchases of vehicles with new safety technology that might result from higher vehicles prices associated with more stringent CAFE standards. A number of commenters noted that since these improvements will be driven by crash avoidance technologies, they will also benefit older vehicles and reduce their fatality rates as well. For example, CARB noted that “safety improvements generally provide systematic safety benefits to all vehicles in the on-road fleet, not only to new vehicles. However, NHTSA’s safety model assigns safety coefficients to vehicles solely based on their model year and it fails to incorporate the effect that new safety designs and technologies will have on systematically improving fleet-wide on-road safety.” IPI similarly noted that should “new safety technologies be adopted, the predicted fatalities for all the older vehicle vintages will have to be lowered as well because effective crash avoidance technologies will lower all vehicles’ fatality costs.”

The agencies agree that the users of older vehicles will also benefit from crash avoidance technologies on newer vehicles. In response, the agencies have modified our methodology to reflect lower fatality rates on older vehicles resulting from the new crash avoidance technologies. Crash avoidance technologies prevent crashes from happening and thus benefit both the vehicle with the technology and any other vehicles that it might have collided with. However, the scope of these impacts on older vehicle’s fatality rates are somewhat limited due to several factors:

- Single vehicle crashes, which make up about half of all fatal crashes, will not be affected. Only multi-vehicle crashes involving a newer vehicle with the advanced technology and an older vehicle will be affected. Multi-vehicle crashes account for roughly half of all light vehicle occupant fatalities.
- For a new safety technology to benefit an older vehicle in a multi-vehicle crash, the vehicle with the technology must have been in a position to control, or prevent the crash. For example, in front-to-rear crashes which can be addressed by FCW and AEB, the older vehicle would only benefit if it was the vehicle struck from behind. If the struck vehicle were the newer vehicle, its AEB technology would not prevent the crash. Logically this would occur in roughly half of two-vehicle crashes and a third of all three-vehicle crashes. Since most multi-vehicle crashes involve only two vehicles, roughly half of all multi-vehicle crashes might qualify.
- The benefits experienced by older vehicles are proportional to the probability that the vehicles they collide with are newer vehicles with advanced crash avoidance technology. The agencies estimate that the probability that this would occur is a function of the relative exposure of vehicles by age, measured by the portion of total VMT driven by vehicles of that age. Based on VMT schedules (*see* CY 2016 example in [Table II-148](#)~~Table I-11~~), new (current MY) vehicles account for about 9.6 percent of annual fleet VMT. The relevant portion would increase over time as additional MY vehicles are produced with advanced technologies. However, the portion of older vehicle crashes that might be affected by newer technologies is initially very small—only about 2 percent (.5*.5*.096) of older vehicles involved in crashes might benefit from advanced crash avoidance technologies in other vehicles in the first year.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

To reflect this safety benefit for older vehicles, the agencies calculated a revised fatality rate for each older MY vehicle on the road based on its interaction with each new MY starting with MY 2021 vehicles based on the following relationship:

$$\text{Revised fatality rate} = Fm - ((x-y)mnp) + F(1-m)$$

Where: F = initial fatality rate for each MY

x = baseline MY fatality rate

y = current MY fatality rate

m = proportion of occupant fatalities that occur in multi-vehicle crashes (52 percent)

n = probability that crash is with a new MY vehicle containing advanced technologies

p = probability that new vehicle is “striking” vehicle

The initial fatality rate for each vehicle MY (F) was derived by combining fatality counts from NHTSA’s Fatality Analysis Reporting System (FARS) with VMT data from IHS/Polk.

The baseline MY fatality rate (x) represents the baseline rate over which the impact of new crash avoidance technologies should be measured. It establishes the baseline rate for each MY that will be compared to the most current MY rate to determine the change in fatality rate (FR) for each MY. The relative effectiveness of new crash-avoidance technologies in modifying the fatality rate of older model vehicles is measured differently depending on the age of the older vehicle. The fatality rate is a historical measure that reflects safety differences due to both crashworthiness technologies such as air bags and crash avoidance technologies such as electronic stability control, but up through MY 2017, crashworthiness standards are the predominant cause of these differences.

The most recent significant crashworthiness safety standard, which upgraded roof strength standards which was effective in all new passenger vehicles in MY 2017. Crashworthiness standards would not have secondary benefits for older MY vehicles. Post MY 2017, the agencies believe crash avoidance technologies will drive safety improvements. To isolate the added crash avoidance safety expected in newer vehicles, the marginal impact of the difference between the MY 2017 fatality rate and the most current MY fatality rate represents the added marginal effectiveness of new crash-avoidance technologies of each subsequent MY for MYs 2017 and earlier. Beginning with MY 2018, the difference between the older MY fatality rate and most current MY rate determines the potential safety benefit for the older vehicles.

The current MY fatality rate (y), represents the projected fatality rate of future MY vehicles after adjustment for the impacts of the advanced crash avoidance technologies and projected improvements in non-technology factors examined in this analysis. This process was discussed in detail in the previous section.

The proportion of passenger vehicle occupant fatalities that occur in multi-vehicle crashes (m), was derived from an analysis of occupants of fatal passenger vehicle crashes from 2002-2017 FARS. The analysis indicated that 47.8 percent of fatal crash occupants were in single vehicle crashes, 40.2 percent were in two vehicle crashes, and 12 percent were in crashes involving 3 or more vehicles. Overall, 52.2 percent were in multi-vehicle crashes.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The portion of older vehicle crashes involving newer vehicles containing advanced crash avoidance technologies (n), is assumed to be equal to the cumulative risk exposure of vehicles that have these technologies. This exposure is measured by the product of annual VMT by vehicle age and registrations of vehicles of that age. The CAFE model calculates this dynamically, but as an example, based on 2016 registration data (see [Table II-148](#)~~Table I-11~~ above), the most current MY would represent 9.6 percent of all VMT in a calendar year, implying a 9.6 percent probability that the vehicle encountered would be from the most current MY. This percentage would increase for each CY as more MY vehicles adopt advanced crashworthiness technologies. The agencies note that other factors such as uneven concentrations of newer vs. older vehicles or improved crash avoidance in the younger vehicles already on the road that are the basis for the agencies' VMT proportion table might disrupt this assumption, but it is likely that this would only serve to slow the probability of these encounters, making this a conservative assumption in that it maximizes the probability that older vehicles might benefit from newer technologies.

The probability that the vehicle with advanced crash avoidance technology is the controlling or striking vehicle (p), was calculated using the relative frequency of fatal crash occupants in multi-vehicle crashes. As noted previously, 40.2 percent were in two vehicle crashes, and 12 percent were in crashes involving 3 or more vehicles. The agencies assume a probability of 50 percent for two vehicle crashes and 33 percent for crashes with 3 or more vehicles. Weighted together the agencies estimate a 46.1 percent probability that, given a multi-vehicle crash involving a vehicle with advanced technologies and an older vehicle without them, the newer vehicle will be the striking vehicle or in a position where its crash avoidance technologies might influence the outcome of the crash with the older vehicle.

This process is illustrated in [Table II-149](#)~~Table I-12~~ below for adjustments due to improvements in MY 2021 vehicles back through MY 1995. In [Table II-149](#)~~Table I-12~~, the actual model year fatality rate is shown in the second column. As noted above, the base fatality rate, shown in column 3, is the MY 2017 rate for all MYs prior to 2018, after which it becomes the actual MY rate. Column 4 shows the difference between the fatality rate for MY 2021 and the base rate for each MY. Column 5 shows the resulting revised fatality rate that would be used for each older MY, and column 6 and 7 list the change in that rate. The various factors noted in the above formula are applied in column 5. The results indicate a 0.006 decrease in pre-2018 MY vehicles fatality rates, with declining impacts going forward to MY 2021. In subsequent years, this impact would grow to reflect the both the increased probability that an older vehicle would crash with vehicles containing advanced technology, as well as the increased technology levels in progressively newer vehicles. This table was created using NPRM inputs and is provided for explanatory purposes only. The actual impacts are dynamically calculated within the Volpe model and reflect revised fatality rate trends going forward and cover even older model years.

(e) *Dynamic Fleet Composition*

As described in the sales discussion in Section [cross-cite to Dynamic Fleet Share in Sales Section], the standards may impact the distribution of cars and trucks purchased. As light trucks, SUVs and passenger cars respond differently to technology applied to meet the standards—namely mass reduction—fleets with different compositions of body styles will have varying amounts of fatalities. Since mass-safety fatalities are calculated by multiplying mass point-estimates by VMT, which implicitly captures the impact of the dynamic fleet share model, the estimates of mass-safety fatalities in the previous section include the impact of vehicle prices on fleet composition.

c) *Impact of Rebound Effect on Fatalities*

The “rebound effect” is a measure of the additional driving that occurs when the cost of driving declines. More stringent standards reduce vehicle operating costs, and in response, some consumers may choose to drive more. Driving more increases exposure to risks associated with on-road transportation, and

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

this added exposure translates into higher fatalities. The agencies have calculated this impact by estimating the change in VMT that results from alternative standards.

As noted previously, rebound miles are not imposed on consumers by regulation. They are a freely chosen activity resulting from reduced vehicle operational costs. As such, the agencies believe a large portion of the safety risks associated with additional driving are offset by the benefits drivers gain from added driving. For the proposal, the agencies assumed that, in deciding to drive more, drivers internalize the full cost to themselves and others, including the cost of accidents, associated with their additional driving.

In response to the NPRM, EDF noted that consumers may not fully value the added safety risk, such as risk to other drivers.²⁰⁴¹ In making this point, EDF suggested a value of 50 percent would be conservative, but did not provide supporting evidence for that value. The agencies agree that the level of risk internalized by drivers is uncertain, and for the final rule have revised the portion of the added monetized safety risk that consumers internalize to 90 percent, which mostly offsets the societal impact of any added fatalities from this voluntary consumer choice.

The actual portion of risk from crashes that drivers internalize is unknown. The agencies suspect that drivers are more likely to internalize serious crash consequences than minor ones, and some drivers may not perfectly internalize injury consequences to other individuals, especially occupants of other vehicles and pedestrians. However, legal consequences from crash liability, both criminal and civil, should also act as a caution for drivers considering added crash risk exposure. We considered several approaches to estimating internalized crash risk. The first assumes that drivers value harm to themselves as well as legal liability for causing harm to others. It considers that all fatalities in single vehicle crashes are fully valued, that there is roughly a 50 percent chance that each driver would be the one killed in multi-vehicle crashes, and that there is roughly a 50 percent chance that each driver would be at-fault in a multi-vehicle crash that they survived. This produces an estimate of roughly 87 percent. Another approach assumes that drivers fully value all damage in single vehicle crashes, and only discount property damage incidents in multi-vehicle crashes. Based on data in Blincoe, *et al.* (2015),²⁰⁴² multi-vehicle property-damage-only crashes account for about 7 percent of all societal crash costs, leaving 93 percent recognized under this approach. Yet another approach would assume drivers value injury crashes, but discount non-injury related costs such as property damage and traffic congestion. This approach results in roughly an 88 percent estimate of costs internalized. Overall, while we recognize this proportion is uncertain, we believe it is reasonable to assume that drivers internalize 90 percent of the crash risk that results from added driving.

IPI commented that “the accident related costs associated with the increase in driving that results from the scrappage and dynamic fleet share models—which is also ‘freely chosen’—are inexplicably and unjustifiably not offset by countervailing mobility benefits in the benefit cost analysis—and the agencies inappropriately claim that these traffic fatalities—which comprise the other half of the 12,700 projection—also justify the roll back.”²⁰⁴³ In this comment, IPI has erroneously conflated the rebound effect and the scrappage effect. The agencies have appropriately accounted for the additional value consumers get out of increases in fuel efficiency, which manifest in two ways: reductions in fuel costs, and the additional driving resulting from the reductions in per-mile fuel costs. The agency cannot appropriately consider one without

²⁰⁴¹ EDF, Appendix B, NHTSA-2018-0067-12108, at 101.

²⁰⁴² Blincoe, L., Miller, T.R., Zaloshnja, E., Lawrence, B. A., (May 2015, Revised) *The Economic and Societal Impact of Motor Vehicle Crashes*, 2010, (DOT HS 812 012), National Highway Traffic Safety Administration, Washington, D.C.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

the other, as the two effects trade off, one against the other, according to consumer preferences between the two.

The scrappage effect represents the behavior of consumers when their choices are restricted by more stringent fuel economy standards. For instance, the consumer loses lower-price and less fuel-efficient bundles of vehicle attributes that would be available in the absence of more stringent alternatives. If anything, these consumers experience an un-estimated cost regarding the lost utility from being priced out of the new car market and being forced to drive an older, less safe—and likely less fuel efficient—vehicle. That the agencies have assessed the benefits of the rebound effect by assuming they are at least as great as 90 percent of the additional safety costs of rebound driving, does not mean that other channels of safety effects must be offset. IPI’s characterization of this reduction in choices as a “freely-chosen” outcome is misleading. However, the agencies did evaluate whether the sales, scrappage, and dynamic fleet share model could lead to changes in fuel economy in the legacy fleet that may result in significant changes in VMT and/or fuel economy. Upon further review, the agencies determined that such an effect—if it were to exist—would be very small and would not impact the analysis meaningfully, so the agencies declined to include this effect in the final rule’s analysis.

d) *Fatalities by Source*

For the NPRM, the agencies calculated rebound fatalities by running the model with a 20 percent rebound assumption and again with a 0 percent rebound assumption. The following difference was assumed to assign the change in fatalities of the rule due to rebound:

$$\text{Rebound Fatalities} = (\text{Fatalities}_{\text{Alt},20\%} - \text{Fatalities}_{\text{Alt},0\%}) - (\text{Fatalities}_{\text{Aug},20\%} - \text{Fatalities}_{\text{Aug},0\%})$$

Similarly, the agencies calculated mass reduction fatalities by running the model using the central assumptions about coefficients on delta curb weight and again setting these coefficients to 0, so that a change in mass reduction would not affect the fatality rate of a vehicle. The following difference assigned the change in fatalities of the rule due to changes in mass reduction levels:

$$\Delta\text{CW Fatalities} = (\text{Fatalities}_{\text{Alt},\text{MR}} - \text{Fatalities}_{\text{Alt},\text{NoMR}}) - (\text{Fatalities}_{\text{Aug},\text{MR}} - \text{Fatalities}_{\text{Aug},\text{NoMR}})$$

Where “Alt” represents the alternative being estimated, “Aug” is the augural or baseline, “MR” stands for mass reduction, and “NoMR” means no mass reduction or mass reduction equaling zero.

The NPRM modeling then assumed that the remaining incremental fatalities were due to changes in sales, scrappage, and the dynamic fleet share. This can be represented by the following:

$$\text{Sales/Scrap Fatalities} = (\text{Fatalities}_{\text{Alt}} - \text{Fatalities}_{\text{Aug}}) - \text{Rebound Fatalities} - \Delta\text{CW Fatalities}$$

The changes to the VMT model (mainly the constraint that fixes total non-rebound VMT to be constant across alternatives) necessitated revising how fatalities are partitioned by source. The number of vehicles of each regulatory class and age changes in each regulatory alternative. Because of this, taking the increment of the rebound fatalities solved in each scenario as described above would capture changes both to the usage per vehicle from rebound, but also differences in the number of vehicles. This would wrongly attribute some of the sales and scrappage fatalities to rebound. Similarly, taking the increment of the mass reduction fatalities solved in each scenario as described above would capture the changes both to the fatality rate for vehicles (from mass reduction) and the difference in the number of vehicles across alternatives. This

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

would likewise have the potential of wrongly attributing the source of sales and scrappage fatalities to mass reduction.

Instead of computing the fatalities due to rebound in each scenario and then taking the incremental values across alternatives, we compute rebound fatalities by taking the difference in per vehicle rebound miles in the regulatory alternative and the augural case multiplied by the augural fatality rate per mile and augural vehicle count. Holding the number of vehicles constant addresses the concern about the NPRM fatality allocation method wrongly attributing rebound fatalities to the sales and scrappage models. Fatalities due to rebound are computed as follows:

$$Rebound\ Fatalities_{Alt} = \left[\frac{R\ VMT_{Alt} - NR\ VMT_{Alt}}{Veh_{Alt}} - \frac{R\ VMT_{Aug} - NR\ VMT_{Aug}}{Veh_{Aug}} \right] * Fatality\ Rate_{Aug} * Veh_{Aug}$$

Where “RVMT” is VMT including rebound miles, “NRVMT” is VMT excluding rebound miles, “Veh” is the quantity of vehicles, and “Alt” and “Aug” have the same meaning described above. The rebound fatalities will show as zero for the augural scenario, and all alternatives will show fatalities due to rebound miles using the augural vehicle counts.

The fatalities due to mass reduction will use the augural vehicle counts, augural per vehicle VMT including rebound—this simplifies to total VMT including rebound, as shown below. Using a constant vehicle count addresses the concern of the NPRM method wrongly assigning some mass reduction fatalities to the sales and scrappage models. As with the fatalities attributable to rebound, the fatalities attributable to changes in mass reduction are calculated inherently as incremental values, relative to the augural standards (the values will appear as zero for augural standards in the outputs). The equation used to calculate the fatalities due to curb weight changes is as follows:

$$\Delta CW\ Fatalities_{Alt} = (Fatality\ Rate_{Alt} - Fatality\ Rate_{Aug}) * R\ VMT_{Aug}$$

The agencies then computed the sales/scrappage fatalities as the remainder, as was done in the NPRM.

$$Sales/Scrap\ Fatalities = (Fatalities_{Alt} - Fatalities_{Aug}) - Rebound\ Fatalities - \Delta CW\ Fatalities$$

e) *Adjustment for Non-Fatal Crashes*

Fatalities are valued as a societal cost within the CAFE models’ cost and benefit accounting. Their value is based on the comprehensive value of a fatality, which includes lost quality of life and is quantified in the value of a statistical life (VSL) as well as economic consequences such as medical and emergency care, insurance administrative costs, legal costs, and other economic impacts not captured in the VSL alone. These values were derived from data in Blincoe et al. (2015), adjusted to 2018 economics, and updated to reflect the official DOT guidance on the value of a statistical life. This gives a societal value of \$10.4 million for each fatality, which is an update to the value used in the NPRM.²⁰⁴⁴ The CAFE safety model estimates traffic fatalities but does not directly estimate the corresponding non-fatal injuries and property damage that would result from the same factors that influence fatalities. To address this, the agencies developed an adjustment factor applied to fatality costs that accounts for these crashes and related costs. The

²⁰⁴⁴ The NPRM used a societal value of \$9,900,000 in 2016 dollars.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

agencies' approach to estimating non-fatal costs remains relatively unchanged from the proposal, however the agencies have made one minor adjustment to account for advance crash technologies as advocated by commenters.

In the proposal, development of this factor was premised on the assumption that non-fatal crashes would be affected by the standards in proportion to their current nationwide rate of incidence and severity. The agencies assumed the injury profile—the relative number of crashes of each injury severity level that occur nationwide—would increase or decrease congruent with changes in fatalities, meaning that the ratio between fatal and non-fatal costs remained constant across alternatives. The agencies recognized that this may not be the case, but did not have data to support individual injury estimates across injury severities. The agencies provided several explanations as to why a proportionality assumption may be an oversimplification.²⁰⁴⁵ For example, the agencies reviewed NHTSA's separate analysis of traffic crash data showing that older model year vehicles are generally less safe than newer vehicles, meaning fatalities would comprise a larger portion of the total injury picture for older vehicles. This would imply lower ratios across the non-fatal injury and property damage only (PDO) crash profiles and would imply the adjustment overstates total societal impacts

As noted previously, in response to requests by commenters, the agencies have added the estimated impact of six advanced crash avoidance technologies that are currently being deployed commercially to their analysis of future fatality rates. The same data and methods described previously in this section to compute the impact of advanced crash avoidance technologies on fatalities can also be used to examine the effectiveness of these technologies against non-fatal and PDO crashes. The inputs and results are summarized for nonfatal injuries in [Table II-150Table VI-209](#) through [Table II-152Table VI-211](#), and for PDOs in [Table II-153Table VI-212](#) through [Table II-155Table VI-214](#).²⁰⁴⁶

Based on a comparison of the combined average effectiveness impacts for the three crash severity groups (fatalities, non-fatal injuries, and property damage), it is apparent that these advanced crash avoidance technologies would reduce non-fatal injuries and property damage crashes by even more

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

than they would fatalities.²⁰⁴⁷ To explore the scope of this impact, the agencies developed an adjustment factor that reflects the ratio of the decline in the rate of non-fatal crashes to that of fatal crashes. This factor would hypothetically affect the portion of safety improvement that is attributable to safety technologies. The adjustments were based on the cumulative fatality rates (for all three technology groups) by model year, noted in [DMT cross-reference Table “Phased Impact of Crashworthiness Technologies on Fatality Rates, Forward Collision Crashes”] for fatalities, [Table II-152Table VI-214](#) for non-fatal injuries, and [Table II-155Table VI-214](#) for PDOs, which are listed by MY in the last column of [Table II-152Table VI-214](#) and [Table II-155Table VI-214](#). These factors would modify the original non-fatal impacts—which were derived using an assumption that they were proportional to fatal impacts—to reflect the higher effectiveness of these technologies against non-fatal crashes.

The agencies considered including this additional adjustment factor to account for the *additional* cost savings attributable to advance crash avoidance technologies. The impact of such a factor would decrease the incidence and severity, and thus the costs of nonfatal crashes in regulatory alternatives where new vehicle sales increase, including the preferred alternative. The agencies ultimately erred on the side of caution for this rulemaking and have excluded this factor. Therefore, today’s analysis assumes that advance crash avoidance technologies impact non-fatal and PDO crashes to the same extent as fatal crashes. The agencies will consider including an adjustment for non-fatal and PDO crashes in future rulemakings.

The original proportionality-based adjustment factor, which is described in detail in the following paragraphs, was derived from Tables 1-8 and I-3 in Blincoe et al. (2015). Incidence in Table I-3 in Blincoe et al. reflects the Abbreviated Injury Scale (AIS), which ranks nonfatal injury severity based on an ascending 5 level scale with the most severe injuries ranked as level 5.²⁰⁴⁸

Table 1-3 in Blincoe *et al.* lists injured persons with their highest (maximum) injury determining the AIS level. This scale is represented in terms of maximum abbreviated injury scale (MAIS) level. MAIS0 refers to uninjured occupants in injury vehicles, MAIS1 injuries are generally considered minor (e.g., a superficial laceration) with no probability of death, MAIS2 injuries are generally considered moderate (e.g., a fractured sternum) with a 1-2 percent probability of death, MAIS3 injuries are serious (e.g., open fracture of the humerus) with an 8-10 percent probability of death, MAIS4 injuries are severe (e.g., perforated trachea) with a 5-50 percent probability of death, and MAIS5 injuries are critical (e.g., rupture liver with tissue loss) with a 5-50 percent probability of death. Counts for PDO’s refer to vehicles in which no one was injured. From [Table II-156Table VI-215](#), ratios of injury incidence/fatality are derived for each injury severity level as follows:

Table II-~~156~~²²⁹ - Ratio of Injury Incidence/Fatality; Police Reported and Unreported Crashes

Injury Level	Ratio
PDO	560.88

²⁰⁴⁷ For example, for MY 2035, the combined effectiveness for PDO crashes is .224784, as shown in the second to last column of [Table II-155Table VI-6](#), which is 2.613 times the .0860 combined effectiveness for fatalities, as seen in the final table from the *Crash Avoidance* discussion above, which shows the disproportional impact of crash avoidance technologies on non-fatal accidents.

²⁰⁴⁸ More information on the basis for these classifications is available from the Association for the Advancement of Automotive Medicine at <https://www.aaam.org/abbreviated-injury-scale-ais/>.

MAIS0	138.89
MAIS1	104.83
MAIS2	10.26
MAIS3	3.05
MAIS4	0.52
MAIS5	0.17
Fatal	1

For each fatality that occurs nationwide in traffic crashes, there are 561 vehicles involved in PDOs, 139 uninjured occupants in crashes which resulted in at least one injury,²⁰⁴⁹ 105 minor injuries, 10 moderate injuries, 3 serious injuries, and fractional numbers of the most serious categories which include severe and critical nonfatal injuries. For each fatality ascribed to the standards, it is assumed there will be non-fatal crashes in these same ratios.

Property damage costs associated with delayed fleet turnover must be treated differently than rebound- and mass-related costs because crashes that involve vehicles that are retained longer due to the standards involve damage to older, used vehicles instead of newer vehicles.²⁰⁵⁰ Used vehicles are worth less and will cost less to repair, if they are repaired at all. The consumer's property damage loss is thus reduced by longer retention of these vehicles. To estimate this loss, average new and used vehicle prices were compared. New vehicle transaction prices were estimated from a study published by Kelley Blue Book.²⁰⁵¹ Based on this data, the average new vehicle transaction price in January 2017 was \$34,968. Used vehicle transaction prices were obtained from Edmunds Used Vehicle Market Report published in February of 2017.²⁰⁵² Edmunds data indicate the average used vehicle transaction price was \$19,189 in 2016. There is a minor timing discrepancy in these data because the new vehicle data represent January 2017, and the used vehicle price is for the average over 2016. The agencies were unable to locate exact matching data, but believe the difference is minor and negligible.

Based on these data, new vehicles are on average worth 82 percent more than used vehicles. To estimate the effect of higher property damage costs for newer vehicles in crashes, the per unit property damage costs from Table I-9 in Blincoe et al. (2015) were multiplied by this factor.²⁰⁵³ Results are illustrated in [Table II-157Table VI-216](#).

²⁰⁴⁹ Uninjured passengers incur a cost despite being uninjured. For example, they are often transported to emergency care even though uninjured resulting in lost time and productivity; furthermore, their vehicle might be damaged even though they are uninjured.

²⁰⁵⁰ The agencies note that property damage costs are the costs realized given an accident has occurred. The disparity of incidence rates between new and older vehicles is accounted for above in the fatality calculations.

²⁰⁵¹ Press Release, "New-Car Transaction Prices Remain High, Up More Than 3 Percent Year-Over-Year in January 2017, According to Kelley Blue Book," February 1, 2017, *available at* <https://mediaroom.kbb.com/2017-02-01-New-Car-Transaction-Prices-Remain-High-Up-More-Than-3-Percent-Year-Over-Year-In-January-2017-According-To-Kelley-Blue-Book>.

²⁰⁵² Edmunds Used Vehicle Market Report, February 2017. Available at https://dealers.edmunds.com/static/assets/articles/2017_Feb_Used_Market_Report.pdf.

²⁰⁵³ The original unit costs were derived from vehicles involved in crashes, which are predominately used vehicles. While not precise, we assume this average cost is a reasonable proxy for the property damage to a used vehicle.

Table II-157230 - Property Damage Unit Cost Savings from Retained Used Cars

	Original	Unit Cost
Injury Level	Unit Cost	Savings
PDO	\$2,444	\$2,007
MAIS0	\$1,828	\$1,501
MAIS1	\$5,404	\$4,438
MAIS2	\$5,778	\$4,745
MAIS3	\$10,882	\$8,937
MAIS4	\$16,328	\$13,409
MAIS5	\$15,092	\$12,394
Fatal	\$11,212	\$9,208

The total property damage cost reduction was then calculated as a function of the number of increased fatalities due to stricter CAFE and CO₂ standards as follows:

$$S = \sum_{i=8}^n Fr_n p_n$$

Where:

- S = total property damage reductions from retaining used vehicles longer
- F = increase in fatalities estimated due to used vehicles being retained longer because of stricter standards
- r = ratio of non-fatal injuries or PDO vehicles to fatalities
- p = value of property damage prevented by retaining older vehicle
- n = the 8 injury severity categories

The number of fatalities ascribed to the standards because of slower fleet turnover was multiplied by the unit cost per fatality from Table I-9 in Blincoe et al. (2015) to determine the societal impact of fatalities.²⁰⁵⁴ After subtracting the total reductions in property damage from this value, we divided the fatality cost by it to estimate that overall, fatalities account for 39 percent of the total costs that would result from older vehicle retention.

These calculations are summarized as follows:

$$SV = Fv/x - S$$

Where -

- SV = Value of societal impacts of all crashes resulting from changes to fleet turnover

²⁰⁵⁴ Note—These calculations used the original values in the Blincoe et al. (2015) tables without adjusting for economics. These calculations produce ratios and are thus not sensitive to adjustments for inflation.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- F = Increase in fatalities estimated due to retaining used vehicles longer because of stricter standards
- v = Comprehensive societal value of preventing 1 fatality
- x = Percent of total societal loss from crashes attributable to fatalities
- S = total property damage reductions from retaining used vehicles longer

For the fatalities that occur because of mass effects or to the rebound effect, the calculation was more direct, a simple application of the ratio of the portion of costs produced by fatalities to the change in fatalities; there is no need to adjust for property damage because all impacts were derived from the mix of vehicles in the on-road fleet. Again, from Table I-8 in Blincoe et al. (2015), the agencies derived this ratio based on all cost factors including property damage to be 36 percent.

For purposes of application in the CAFE model, these two factors (the factor for sales/scrappage, and the factor for mass and rebound) were combined based on the relative contribution to total fatalities of different factors. As noted previously, although a safety impact from the rebound effect is calculated, these impacts are considered to be freely chosen rather than imposed by the standards and imply personal benefits at least equal to the sum of their added operational costs and the portion of safety consequences internalized. However, the agencies still calculate and report the impacts of the rebound effect to provide a comprehensive view of the impacts of the standards. There are two different factors depending on which metric is considered (total impacts or CAFE imposed impacts). The agencies created these two adjustment factors by weighting components by the relative contribution to changes in fatalities associated with each component. This process and results are shown in [Table II-158](#)~~Table VI-247~~. Note that due to programming constraints, the agencies applied the average weighted factor to all fatalities. This will tend to overstate costs slightly because of sales and scrappage and to understate costs associated with mass and rebound.

Table II-~~158~~²³⁴ - Contributing Factors of Societal Impacts

	Fatalities		Weights
Contributing Factor	Portion of	Weights -	CAFE Imposed
	Crash Costs	All Factors	Factors
Sales and Scrappage	0.3903	0.140	0.969
Rebound Effect	0.3611	0.855	
Mass	0.3611	0.005	0.0311
Total	NA	1	1
Weighted Factor		0.37	0.39

f) *Summary of Safety Impacts*

Table I

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

~~Table I-218~~ through

Table I

~~Table I-221~~ summarize the safety effects of CAFE standards across the various alternatives under the 3 percent and 7 percent discount rates.

Table I

~~Table I-222~~ through ~~Table I-225~~ summarize these impacts for CO₂ standards. As noted in Section VI.D.2.e, societal impacts are valued using a \$10.4 million value per statistical life (VSL). Note that fatalities in these tables are undiscounted—only the monetized societal impact is discounted.

These tables present aggregations or averages of results for calendar years through 2050. Underlying model output files provide results for each model year in each calendar year.²⁰⁵⁵ These results can be used for more detailed review and analysis of estimated trends. For example, for each calendar year through 2050, the following two tables—one for CAFE standards and one for CO₂ standards—show (a) the number of light-duty vehicles in service, (b) the travel accumulated by those vehicles, and (c) the total number fatalities among the types included in today's analysis.

The analysis shows the annual number of fatalities for the final standards growing more slowly than under the baseline standards, reflecting the combined effects of fleet turnover, mass reduction, and shifts between passenger cars and light trucks in the new vehicle fleet.

Table I-226 summarizes the non-fatal safety impacts under alternative CAFE and CO₂ standards:

The Pennsylvania Department of Environmental Protection commented that the agencies did not fully account for safety improvements associated with the augural standards.²⁰⁵⁶ The agencies note that the analysis accounts for the safety impacts of mass reduction, sales and scrappage, rebound, vehicle model year and vehicle age for each of the alternatives relative to the augural baseline. The commenter did not provide any specific items that were omitted from the analysis. The agencies believe the analysis thoroughly assesses the safety effects of all the alternatives.

3. Simulating Environmental Impacts of Regulatory Alternatives

This final rulemaking predominantly addresses fuel economy of the light-duty vehicle fleet in the United States through different technologies to improve efficiency. Inherently, these technologies will reduce the fuel consumed and therefore impact CO₂ and other greenhouse gases foremost. Certain technologies will also impact air quality through changes to criteria pollutants and air toxics emitted at the tailpipe as well as upstream of the fuel source. Upstream emissions for conventional fuels occur during crude oil extraction, transportation, refining, and the transportation, storage, and distribution of the finished fuel. For electricity, upstream emissions are dependent on the mix of feedstocks such as coal, natural gas, nuclear, and renewable sources for power generation. Similarly, specific hydrogen production pathways

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

such as natural gas reforming or electrolysis of water molecules will determine the upstream emissions of hydrogen fuel. Emission impacts are described in greater detail in the following sections.²⁰⁵⁷

The impacts of both greenhouse gases (GHGs) and criteria pollutant emissions that result from changes in vehicle usage and fuel consumption were estimated and considered as part of this analysis. GHGs are gaseous constituents in the atmosphere, both natural and anthropogenic, and absorb infrared radiation. Primary GHGs in the atmosphere are water vapor, CO₂, nitrous oxide (N₂O), methane (CH₄), and ozone. Criteria air pollutants include carbon monoxide (CO), nitrogen dioxide (NO₂) (one of several oxides of nitrogen), ozone, sulfur dioxides (SO₂), particulate matter (including fine particulate matter, or PM_{2.5}), and lead. Vehicles do not directly emit ozone, but ozone impacts are evaluated based on emissions of the ozone precursor pollutants nitrogen oxides (NO_x) and volatile organic compounds (usually referred to as VOC). These pollutants are emitted during vehicle storage and use, as well as throughout the fuel production and distribution system. While increases in domestic fuel refining, storage, and distribution that result from higher fuel consumption will increase emissions of these pollutants, reduced vehicle use associated with the fuel economy rebound effect will decrease their emissions. The net effect of CAFE and CO₂ standards on total emissions of each criteria pollutant depends on the relative magnitudes of increases in its emissions during fuel refining and distribution, and decreases in its emissions resulting from vehicle use. Because the relationship between emissions in fuel refining and vehicle use is different for each criteria pollutant, the net effect of fuel consumption on total emissions of each pollutant differs between regulatory alternatives.

a) *Climate Change and CO₂ Emissions considered in this Rule*

The NPRM described how both agencies consider climate change and GHG emissions under their respective programs for fuel economy and CO₂. As noted in the NPRM, “In 1988, NHTSA included climate change concepts in its CAFE notices and prepared its first environmental assessment addressing that subject.”²⁰⁵⁸ Additionally, NHTSA “cited concerns about climate change as one of its reasons for limiting the extent of its reduction of the CAFE standard for MY 1989 passenger cars.”²⁰⁵⁹ As stated in the NPRM, “Since then, NHTSA has considered the effects of reducing tailpipe emissions of CO₂ in its fuel economy rulemakings pursuant to the need of the United States to conserve energy by reducing petroleum consumption.”²⁰⁶⁰

Similarly, in the NPRM, EPA described that “the primary purpose of Title II of the Clean Air Act is the protection of public health and welfare. EPA’s light-duty vehicle GHG standards serve this purpose, as the GHG emissions from light-duty vehicles have been found by EPA to endanger public health and welfare (see EPA’s 2009 Endangerment Finding for on-highway motor vehicles), and the goal of these standards is to reduce these emissions that contribute to climate change.”²⁰⁶¹ In the NPRM, EPA summarized its purpose for establishing CO₂ standards as follows:

Section 202(a)(1) of the Clean Air Act (CAA) states that “the Administrator shall by regulation prescribe (and from time to time revise) ... standards applicable to the emission of any air pollutant

²⁰⁵⁷ NHTSA also uses the results of the CAFE model to analyze the potential environmental impacts of the regulatory alternatives in its Environmental Impact Statement (EIS). That EIS informs the agency’s decision-making process.

from any class or classes of new motor vehicles ..., which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.” If EPA makes the appropriate endangerment and cause or contribute findings, then section 202(a) authorizes EPA to issue standards applicable to emissions of those pollutants. Indeed, EPA’s obligation to do so is mandatory: *Coalition for Responsible Regulation*, 684 F.3d at 114; *Massachusetts v. EPA*, 549 U.S. at 533.²⁰⁶²

The agencies modeled the estimated physical changes in quantity of CO₂, CH₄, and NO₂ emissions in the NPRM analysis, and conducted additional modeling of climate-related impacts, including sea-level rise, global temperature increases, and ocean pH changes in the Draft EIS accompanying the NPRM. The Draft EIS also included a comprehensive discussion of climate change impacts, drawing from various Intergovernmental Panel on Climate Change (IPCC) reports, the U.S. Global Change Research Program (USGCRP) National Climate Assessment (NCA) reports, and other peer-reviewed reports and assessment reports. The agencies also considered the increase in climate damages from an increase in CO₂ emissions,²⁰⁶³ also known as the social cost of carbon and discussed previously in [Section VI.C.1], above.

Many commenters expressed a desire for more information on the rule’s potential climate impacts, so the discussion has been expanded here and in the Final EIS. Specifically, commenters stated that the agencies failed to address climate change in the proposal, and that the proposal ignored “scores of studies and reports” on climate change published since EPA’s 2009 Endangerment Finding and promulgation of the existing CO₂ and CAFE standards.²⁰⁶⁴ Several commenters presented summaries of climate impacts, citing IPCC, USGCRP, and other reports explicitly relied on in the DEIS, on temperature increases, increases in extreme weather events, ocean warming, acidification, and sea level rise, impacts on the United States’ water supply, human health impacts, impacts to crop productivity and global food security, potential increases in the spread of infectious disease, national security impacts, and impacts to animal and plant species, including Federally protected species, among other impacts.²⁰⁶⁵

In addition to comments stating the agencies had presented too little information on climate change in the NPRM, some commenters disagreed with how the agencies framed the impact of the rule on climate change. Many commenters cited IPCC and USGCRP to reinforce their understanding that human activities are the dominant cause of global warming since the mid-20th century. NHTSA considered both the IPCC and USGCRP reports in the DEIS accompanying the NPRM and in this final rule, and did not dispute those findings. Commenters also cited IPCC and the National Climate Assessments, among other reports, as support to their understanding that regardless of the perceived magnitude of the rule on total CO₂ emissions, any additional actions taken now to reduce CO₂ emissions would affect the degree of climate impacts in the future. Further discussion of these comments occurs in Section VIII.

Just as NHTSA does with both the draft and final EIS, and as EPA did for its *Endangerment and Cause or Contribute Findings for Greenhouse Gases under the Clean Air Act*, for this rule, both agencies relied on existing studies and reports to summarize the current state of climate science and provide a

framework for the analysis of impacts. The agencies drew primarily on panel-reviewed synthesis and assessment reports from the Intergovernmental Panel on Climate Change (IPCC) and the U.S. Global Change Research Program (GCRP), supplemented with past reports from the U.S. Climate Change Science Program (CCSP), the National Research Council, and the Arctic Council and EPA's *Technical Support Document for Endangerment and Cause or Contribute Findings for Greenhouse Gases under the Clean Air Act*,²⁰⁶⁶ which, as stated above, relied on past major international or national scientific assessment reports.

Assessment reports assess numerous individual studies to draw general conclusions about the potential impacts of climate change. Even where assessment reports include consensus conclusions of expert authors, uncertainty still exists, as with all assessments of environmental impacts. Given the global nature of climate change and the need to communicate uncertainty to a variety of decision-makers, IPCC has focused considerable attention on developing a systematic approach to characterize and communicate this information. The IPCC is a United Nations panel, founded in 1988, which evaluates climate science by assessing research on climate change and synthesizing relevant research into major assessment reports. The IPCC provides regular assessments on climate impacts and future risks, and options for adaptation and risk mitigation. The agencies used the system developed by IPCC to describe uncertainty associated with various climate change impacts.

The IPCC reports communicate uncertainty and confidence bounds using commonly understood but carefully defined words in italics to represent likelihood of occurrence. The referenced IPCC documents provide a full understanding of the meaning of those uncertainty terms in the context of the IPCC findings. The IPCC notes that there are two primary uncertainties with climate modeling: model uncertainties and scenario uncertainties:²⁰⁶⁷

- **Model uncertainties.** *These uncertainties occur when a climate model might not accurately represent complex phenomena in the climate system. For some processes, the scientific understanding could be limited regarding how to use a climate model to "simulate" processes in the climate system.*
- **Scenario uncertainties.** *These uncertainties arise because of uncertainty in projecting future GHG emissions, concentrations, and forcings (e.g., from solar activity).*

According to IPCC, these types of uncertainties are described by using two metrics for communicating the degree of certainty: confidence in the validity of findings, expressed qualitatively, and quantified measures of uncertainties, expressed probabilistically.²⁰⁶⁸ The confidence levels synthesize the judgments about the validity of the findings, determined through evaluation of the evidence and the degree of scientific agreement. The qualitative expression of confidence ranges are described, in italics, from *very low* to *very high*, with higher confidence levels assigned to findings that are supported by high scientific agreement. The quantitative expression of confidence ranges from *exceptionally unlikely* to *virtually certain*,

 with higher confidence representing findings supported by robust evidence. [Table II-168](#)~~Table I-25~~ shows that the degree of confidence increases as evidence becomes more robust and agreement is greater.

Table II-~~168~~~~241~~ - Standard Terms to Define the Likelihood of a Climate-Related Event

Likelihood Terminology	Likelihood of the Occurrence/Outcome
Virtually certain	99–100% probability
Very likely	90–100% probability
Likely	66–100% probability
About as likely as not	33–66% probability
Unlikely	0–33% probability
Very unlikely	0–10% probability
Exceptionally unlikely	0–1% probability
Notes: Additional terms that were used in limited circumstances in the IPCC Fourth Assessment Report, extremely likely = 95–100% probability, more likely than not ≥ 50–100% probability, and extremely unlikely = 0–5% probability) were also used in IPCC Working Group I to the Fifth Assessment Report when appropriate, and in the Climate Science Special Report: Fourth National Climate Assessment in 2017 by U.S. Global Change Research Program. Source: IPCC 2013.	

As described in more detail in the Final EIS, the process known as the *greenhouse effect* is responsible for trapping a portion of a planet’s heat in the planet’s atmosphere, rather than allowing all of that heat to be radiated into space. GHGs trap heat in the lower atmosphere (the atmosphere extending from Earth’s surface to approximately 4 to 12 miles above the surface), absorb heat energy emitted by Earth’s surface and lower atmosphere, and reradiate much of it back to Earth’s surface, thereby causing warming. Human activities, particularly fossil-fuel combustion, lead to the presence of increased concentrations of GHGs in the atmosphere; this buildup of GHGs is changing the Earth’s energy balance. IPCC states the warming experienced over the past century is due to the combination of natural climatic forcings (e.g., natural GHGs, solar activity) and human-made climate forcings.²⁰⁶⁹ IPCC concluded, “[h]uman influence has been detected in warming of the atmosphere and the ocean, in changes in the global water cycle, in reductions in snow and ice, in global mean sea-level rise, and in changes in some climate extremes. ... This evidence for human influence has grown since [the IPCC Working Group I (WG1) Fourth Assessment Report (AR4)].

²⁰⁶⁹ IPCC 2013.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

IPCC reports that it is *extremely likely* that human influence has been the dominant cause of the observed warming since the mid-20th century.²⁰⁷⁰

Although the climate system is complex, IPCC has identified the following drivers of climate change:

- **GHGs.** Primary GHGs in the atmosphere are water vapor, atmospheric CO₂, N₂O, CH₄, and ozone.²⁰⁷¹
- **Aerosols.** Aerosols are natural (e.g., from volcanoes) and human-made particles in the atmosphere that scatter incoming sunlight back to space, causing cooling. Some aerosols are hygroscopic (i.e., attract water) and can affect the formation and lifetime of clouds. Large aerosols (more than 2.5 micrometers in size) modify the amount of outgoing long-wave radiation.²⁰⁷² Other particles, such as black carbon, can absorb outgoing terrestrial radiation, causing warming. Natural aerosols have had a negligible cumulative impact on climate change since the start of the industrial era.²⁰⁷³ Further discussion of black carbon and other aerosols is located in Chapter 4 of the FEIS.
- **Clouds.** Depending on cloud height, cloud interactions with terrestrial and solar radiation can vary. Small changes in the properties of clouds can have important implications for both the transfer of radiative energy and weather.²⁰⁷⁴
- **Ozone.** Ozone is created through photochemical reactions from natural and human-made gases. In the troposphere, ozone absorbs and reemits long-wave radiation. In the stratosphere, the ozone layer absorbs incoming short-wave radiation.²⁰⁷⁵
- **Solar radiation.** Solar radiation, the amount of solar energy that reaches the top of Earth's atmosphere, varies over time. Solar radiation has had a negligible impact on climate change since the start of the industrial era compared to other main drivers.²⁰⁷⁶
- **Surface changes.** Changes in vegetation or land surface properties, ice or snow cover, and ocean color can affect surface albedo.²⁰⁷⁷ The changes are driven by natural seasonal and diurnal changes (e.g., snow cover) as well as human influences (e.g., changes in vegetation type).²⁰⁷⁸

Effects of emissions and the corresponding processes that affect climate are highly complex and variable, which complicates the measurement and detection of change. However, IPCC indicates that an increasing number of studies conclude that anthropogenic GHG emissions are affecting climate in detectable

²⁰⁷⁵ IPCC 2013.

²⁰⁷⁶ IPCC 2013.

²⁰⁷⁷ Surfaces on Earth (including land, oceans, and clouds) reflect solar radiation back to space. This reflective characteristic, known as *albedo*, indicates the proportion of incoming solar radiation the surface reflects. High albedo has a cooling effect because the surface reflects rather than absorbs most solar radiation.

and quantifiable ways.^{2079,2080} GHGs occur naturally and because of human activity. Other GHGs, such as the fluorinated gases,²⁰⁸¹ are primarily anthropogenic in origin and are used in commercial applications such as refrigeration and air conditioning and industrial processes such as aluminum production.

In its most recent assessment of climate change (*IPCC WG1 AR5*), IPCC states that, “Warming of the climate system is unequivocal, and since the 1950s, many of the observed changes are unprecedented over decades to millennia. The atmosphere and ocean have warmed, the amounts of snow and ice have diminished, sea level has risen, and the concentrations of greenhouse gases have increased.”²⁰⁸² IPCC concludes that, at continental and global scales, numerous long-term changes in climate have been observed. To be more specific, IPCC and the GCRP include the following trends observed over the 20th century as further supporting the evidence of climate-induced changes:

- Most land areas have very likely experienced warmer and/or fewer cold days and nights along with warmer and/or more frequent hot days and nights.^{2083,2084} From 1880 to 2016, the global mean surface temperature rose by about 0.9°C (1.6°F).²⁰⁸⁵ Air temperatures are warming more rapidly over land than over oceans.^{2086,2087} Similar to the global trend, the U.S. average temperature is about 1.8°F warmer than it was in 1895, and this rate of warming is increasing—most of the warming has occurred since 1970.²⁰⁸⁸ IPCC projects a continuing increase in surface temperature between 2081 and 2100, with a likely range between 0.3°C (0.5°F) and 4.8°C (8.6°F), compared with 1986 through 2005, where the lower value corresponds to substantial future mitigation of carbon emissions.²⁰⁸⁹
- Cold-dependent habitats are shifting to higher altitudes and latitudes, and growing seasons are becoming longer.^{2090,2091} According to the IPCC, “it is virtually certain that there will be more

frequent hot and fewer cold temperature extremes over most land areas on daily and seasonal timescales” and it is very likely that heat wave frequency and duration will also increase.²⁰⁹²

- Sea level is rising, caused by thermal expansion of the ocean and melting of snowcaps and ice sheets.^{2093,2094} Between 1971 and 2010, global ocean temperature warmed by approximately 0.25°C (0.45°F) in the top 200 meters (approximately 660 feet).²⁰⁹⁵ IPCC concludes that mountain glaciers, ice caps, and snow cover have declined on average, further contributing to sea-level rise. Losses from the Greenland and Antarctic ice sheets very likely contributed to sea-level rise from 1993 to 2010, and satellite observations confirm that they have contributed to sea-level rise in subsequent years.²⁰⁹⁶ IPCC projects that the global temperature increase will continue to affect sea level, causing a likely rise of 0.26 meter (0.85 foot) to 0.82 meter (2.7 feet) in the next century.²⁰⁹⁷
- More frequent weather extremes such as droughts, floods, severe storms, and heat waves have been observed.^{2098,2099} Average atmospheric water vapor content has increased since at least the 1970s over land and the oceans, and in the upper troposphere, largely consistent with air temperature increases.²¹⁰⁰ Because of changes in climate, including increased moisture content in the atmosphere, heavy precipitation events have increased in frequency over most land areas.^{2101,2102} Observations of increased dryness since the 1950s suggest that some regions of the world have experienced longer, more intense droughts caused by higher temperatures and decreased precipitation, particularly in the tropics and subtropics.²¹⁰³ Heavy precipitation events have increased globally since 1951, with some regional and subregional variability.²¹⁰⁴ A warmer atmosphere holds more moisture and increases the energy available for convection, causing stronger storms and heavier precipitation.^{2105,2106}
- Oceans are becoming more acidic because of increasing absorption of CO₂ by seawater, which is driven by a higher atmospheric concentration of CO₂.^{2107,2108,2109} There is high

confidence that oceans have become increasingly more acidic.^{2110,2111} A recent assessment found that the oceans have become about 30 percent more acidic over the last 150 years since the Industrial Revolution.²¹¹²

Based on the current trajectory, IPCC projects that the atmospheric CO₂ concentration could rise to more than three times preindustrial levels by 2100.²¹¹³ The effects of the CO₂ emissions that have accumulated in the atmosphere prior to 2100 will persist well beyond 2100. If current trends continue, this elevation in atmospheric CO₂ concentrations will persist for many centuries, with the potential for temperature anomalies continuing much longer.²¹¹⁴

Many commenters expressed concerns about trends of increased temperature, sea level rise, and extreme weather events in relation to climate change impacts from increased GHG emissions. The Joint Submission from Colorado local governments stated “[t]here is overwhelming scientific evidence that CO₂ and other greenhouse gases released into the atmosphere are exerting a profound effect on the earth’s climate—increasing extreme weather events, changing rainfall and crop productivity patterns, and fueling the migration of infectious diseases. Since 1983, average temperatures in Colorado have risen 2°F and continue to rise. Climate change will impact the health of those who live, work, and play in Colorado and around the world.”²¹¹⁵ The California Air Resources Board (CARB) stated that:

[P]rojections show that these effects will continue and worsen over the coming centuries. Changes in weather patterns can influence the frequency of meteorological conditions conducive to the development of high pollutant levels. Some of the key air pollutants (ozone, secondary particulate matter) depend strongly on temperature. Increases in atmospheric GHGs since the Industrial Revolution are well-known to warm global near- surface and tropospheric air temperatures. Some of the other broad range of effects of higher temperatures on air quality could include increases in emissions of biogenic gases year-around, in electric power and vehicle-fuel emissions in summer, in the temperature-dependent rates of photochemical reactions, and vaporization of volatile particle components. Higher temperatures will also impact meteorology by increasing atmospheric stability due to enhanced cloudiness but decreasing in stability due to warmer near-surface temperatures.²¹¹⁶

The agencies received additional public comments on concerns with worsening effects of climate change due to increased GHG emissions. States, localities, and individual commenters summarized broad and specific impacts that climate change would have in their area both in writing and at the three public meetings held on the proposal;²¹¹⁷ for example, the joint submission from Colorado local governments and Colorado municipal agencies stated that “[m]any Colorado communities are already experiencing the

impacts of a destabilized climate in the form of reduced snowpack, earlier snowmelt, increased risk of high-intensity wildfires and their associated air pollution and later flash flooding, extreme weather events, and an increased number of “high heat” days.”²¹¹⁸

Many commenters urged the agencies to consider more stringent standards to address GHG emissions. The Northeast States for Coordinated Air Use Management (NESCAUM) stated that “effectively combatting climate change requires GHG reductions on a national and international scale. Maintaining an aggressive downward trend in transportation sector GHG emissions will not occur in the absence of strong national GHG emission reductions.”²¹¹⁹ Similarly, the Center for Biological Diversity et al. stated “the scientific record is now overwhelming that climate change poses grave harm to public health and welfare; that its hazards have become even more severe and urgent than previously understood; and that avoiding devastating harm requires substantial reductions in greenhouse gas emissions, including from the critically important transport sector, within the next decade.”²¹²⁰ Minnesota Pollution Control Agency (MPCA), the Minnesota Department of Transportation (MnDOT), and the Minnesota Department of Health (MDH) stated “Tackling climate change will require aggressive and immediate action on reducing emissions from the transportation sector. The existing GHG and CAFE standards are a critical piece to the multifaceted and global effort to reduce GHG emissions.”²¹²¹

Commenters also expressed concerns that the agencies did not accurately consider the effects of climate change resulting from the rulemaking. Pennsylvania Department of Environmental Protection (PA DEP) stated “the Proposed Rule does not fully consider the potential effects of global climate change resulting from these forgone reductions or the interests of states in preventing or mitigating the impacts of climate change on their citizens and environment.”²¹²² The Center for Biological Diversity et al. stated “the agencies callously disregard the demonstrated need to reduce emissions sharply over the next decade if severe impacts of a destabilized climate are to be avoided.”²¹²³ Similarly, the Joint Submission from the States of California et al. and the Cities of Oakland et al. stated “discussion of the effect of the Proposed Rollback on GHG emissions significantly understates the outcome,” and “the overwhelming scientific consensus is that immediate and continual progress toward a near-zero GHG-emission economy by mid-century is necessary to avoid truly catastrophic climate change impacts.”²¹²⁴

The agencies have carefully considered these comments in the context of the information on climate change summarized in the NPRM and DEIS, and have updated information for this final rule. The agencies drew upon updates to climate science and impacts for the analysis from reports and studies that were updated or released since the NPRM, including IPCC’s *Global Warming of 1.5 degrees C* report, Volume 2 of the 4th *National Climate Assessment*, and IPCC’s *Special Report on Climate Change and Land*, and the IPCC’s *Special Report on the Ocean and Cryosphere in a Changing Climate*.

The following sections also provide additional context about climate impacts from this final rule; the results of the agencies’ quantitative analysis presented in [P07] shows estimated CO₂, CH₄, and N₂O emissions resulting from the rule, and the discussion of how each agency balanced climate change as a factor

considered in decision-making is presented in [P08]. The Final EIS accompanying today's rule also includes a comprehensive discussion of climate impacts, and additional climate modeling that estimates climate-related effects. As discussed in more detail in the FEIS and following sections, but relevant for placing the following discussion in context, climate modeling performed for this final rule shows the following impacts as a result of the final standards selected: CO₂ concentrations of 789.80 ppm in 2100, compared with 789.11 ppm under the augural standards; global mean surface temperature increases of 3.487°C in 2100, compared with 3.484°C under the augural standards; sea-level rise increases of 76.34 cm in 2100, compared with 76.28 cm under the augural standards; and ocean pH of 8.2172 in 2100, compared with 8.2176 under the augural standards. These equal differences of 0.69 ppm, 0.003°C, 0.06 cm, and -0.0004, respectively. Additionally, the agencies valued anticipated climate-related economic effects in accordance with EO 13783, as discussed in [Section VI.C.1].

(1) Global Greenhouse Gas Emissions

According to NOAA and IPCC, Global atmospheric CO₂ concentrations have increased 46.4 percent, from approximately 278 parts per million (ppm) in 1750²¹²⁵ to approximately 407 ppm in 2018.²¹²⁶ According to IPCC and WRI, in 2014, CO₂ emissions²¹²⁷ accounted for 76 percent of global GHG emissions on a global warming potential (GWP)-weighted basis,²¹²⁸ followed by CH₄ (16 percent), N₂O (6 percent), and fluorinated gases (2 percent).^{2129,2130} IPCC notes that atmospheric concentrations of CH₄ and N₂O increased approximately 150 and 20 percent, respectively, over roughly the same period.²¹³¹

According to WRI, developed countries, including the United States, have been responsible for the majority of historical GHG emissions since the mid-1800s and still have some of the highest GHG emissions per capita.²¹³² While annual emissions from developed countries have been relatively flat over the last few decades, world population growth, industrialization, and increases in living standards in developing countries are expected to cause global fossil-fuel use and resulting GHG emissions to grow substantially. According to IPCC, global GHG emissions since 2000 have been increasing nearly three times faster than in the 1990s.²¹³³ This is further illustrated in [Figure II-48](#)~~Figure I-1~~ figure showing carbon dioxide emissions since 1990 by world region:²¹³⁴

²¹²⁵ IPCC 2013.

Figure II-4879 – Annual CO₂ Emissions (mmt) by World Region, 1990-2012

GHGs are emitted from a wide variety of sectors, including energy, industrial processes, waste, agriculture, and forestry. According to WRI, the energy sector is the largest contributor of global GHG emissions, accounting for 72 percent of global emissions in 2014; other major contributors of GHG emissions are agriculture (10 percent) and industrial processes (6 percent).²¹³⁵ Transportation CO₂ emissions—from the combustion of petroleum-based fuels—account for roughly 15 percent of total global GHG emissions, and have increased by 64 percent from 1990 to 2014.^{2136, 2137}

In general, global GHG emissions continue to increase, although annual increases vary according to factors such as weather, energy prices, and economics. Comparing observed carbon emissions to projected emissions, the current global trajectory is similar to the most fossil fuel-intensive emissions scenario (A1Fi)

²¹³⁵ WRI 2018.

²¹³⁶ The energy sector is largely composed of emissions from fuels consumed in the electric power, transportation, industrial, commercial, and residential sectors. The 15 percent value for transportation is therefore included in the 72 percent value for energy.

in the *IPCC Special Report on Emissions Scenarios* (2000) and the highest emissions scenario (RCP8.5) represented by the more recent Representative Concentration Pathways (RCP).^{2138,2139}

(2) *U.S. Greenhouse Gas Emissions and the Transportation Sector*

Most GHG emissions in the United States are from the energy sector, with the majority of those being CO₂ emissions coming from the combustion of fossil fuels. Fossil fuel combustion CO₂ emissions alone account for 76 percent of total U.S. GWP-weighted emissions, with the remaining 24 percent contributed by other sources such as industrial processes and product use, agriculture and forestry, and waste.²¹⁴⁰ CO₂ emissions due to combustion of fossil fuels are from fuels consumed in the transportation (37 percent of fossil fuel combustion CO₂ emissions), electric power (35 percent), industrial (16 percent), residential (6 percent), and commercial (5 percent) sectors.²¹⁴¹ In 2017, U.S. GHG emissions were estimated to be 6,456.7 MMTCO₂e,²¹⁴² or approximately 14 percent of global GHG emissions.^{2143,2144}

Similar to the global trend, CO₂ is by far the primary GHG emitted in the U.S., representing 82 percent of U.S. GHG emissions in 2017 (on a GWP-weighted basis),²¹⁴⁵ and accounting for 15 percent of total global CO₂ emissions.^{2146,2147} Although CO₂ is the GHG with the largest contribution to warming, methane accounts for 10.2 percent of U.S. GHGs on a GWP-weighted basis, followed by N₂O (5.6 percent) and the fluorinated gases (2.6 percent).²¹⁴⁸

When U.S. CO₂ emissions are apportioned by end use, transportation is the single leading source of U.S. emissions from fossil fuels, causing over one-third of total CO₂ emissions from fossil fuels.²¹⁴⁹ Passenger cars and light trucks account for 59 percent of total U.S. CO₂ emissions from transportation, an increase of 14 percent since 1990.²¹⁵⁰ This increase in emissions is attributed to about 50 percent increase in vehicle miles traveled (VMT) because of population growth and expansion, economic growth, and low fuel prices. Additionally, the rising popularity of sport utility vehicles and other light trucks with lower fuel

²¹³⁸ The Representative Concentration Pathways (RCPs) were developed for the IPCC AR5 report. They define specific pathways to emission concentrations and radiative forcing in 2100. The RCPs established four potential emission concentration futures, a business-as-usual pathway (RCP8.5), two stabilization pathways (RCP6.0, 4.5), and an aggressive reduction pathway (RCP2.6).

economy than passenger cars has contributed to higher emissions.^{2151,2152} Although emissions typically increased over this period, emissions declined from 2008 to 2009 because of decreased economic activity associated with the most recent recession.²¹⁵³

Today's rule addresses light-duty vehicle fuel economy and CO₂ emissions from new-model passenger cars and light trucks. Several commenters observed that the transportation sector accounted for a large, if not the largest, portion of the United States greenhouse gas emissions, and that light-duty vehicle emissions contributed to a large fraction of that portion.²¹⁵⁴ Many commenters referenced the IPCC Report from 2018 on *Global Warming of 1.5 Degrees Celsius*, which considered transportation sector greenhouse gas emissions in describing pathways to limit climate impacts.

Graphically, historical trends in U.S. GHG emissions reported by EPA appear as follows.²¹⁵⁵

*Excluding emissions from land use, land use change, and forestry (LULCF)

Figure II-4980 - Historical U.S. GHG Emissions (million metric tons or MMT CO₂eq) from Light-Duty Vehicles and Other Sectors

Notably, light-duty vehicle CO₂ emissions outweigh other GHG emissions from light-duty vehicles, and light-duty vehicle CO₂ emissions have been relatively stable over a nearly 30-year period during which highway vehicles miles traveled has increased by about 50 percent.²¹⁵⁶ Without fuel economy increases that have accumulated since EPCA's passage in 1975, recent light-duty vehicle CO₂ emissions would have been 50 percent greater than shown above.²¹⁵⁷

For fuel combustion, EIA's National Energy Modeling System (NEMS), which EIA uses to produce its Annual Energy Outlook (AEO) forecasts of U.S. energy consumption and supply, provides corresponding estimates of CO₂ emissions. For the final rule, modeling conducted by the agencies using the AEO2019 version of NEMS shows the following levels of future CO₂ emissions from sectors other than light-duty

²¹⁵⁶ https://www.fhwa.dot.gov/policyinformation/travel_monitoring/historicvmt.pdf.

²¹⁵⁷ DOT reports fuel economy levels of the historical on-road fleet at <https://www.bts.gov/content/average-fuel-efficiency-us-light-duty-vehicles>.

vehicles (which this rule impacts directly) and refineries (which this rule is estimated to impact through changes in fuel consumption):

Figure II-5084 - Projected U.S. CO₂ Emissions (mmt) from Fuel Combustion

As this chart indicates, EIA's representation of laws and regulations current as of AEO2019 shows aggregate emissions from these sectors remaining remarkably stable through 2050, despite projected growth in the U.S. population and economy.

The agencies agree with commenters that the transportation sector, and specifically light-duty vehicle emissions, contribute to the largest portion of the United States' greenhouse gas emissions.²¹⁵⁸ However, the fuel economy and CO₂ of vehicles, regulated in this rulemaking, is not the only determining factor for whether the light-duty transportation sector would see a rise or decline in CO₂ emissions. As discussed elsewhere in this rule, the standards from the final rule affect only new vehicles, which are responsible for approximately 3.5 percent of on-road VMT in any year. The agencies recognize that the revised standards result in additional CO₂ emissions, and these emissions are accounted for in the analysis. It is worthwhile to note that the difference between the augural standard and the new standard is a small change to a small

²¹⁵⁸ See U.S. Energy Information Administration available at <https://www.eia.gov/todayinenergy/detail.php?id=29612> and EPA, Sources of Greenhouse Gas Emissions available at <https://www.epa.gov/ghgemissions/sources-greenhouse-gas-emissions>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

fraction of total VMT, and it is important to consider in context the different mechanisms that contribute to transportation sector greenhouse gas emissions. These mechanisms are considered in the 2018 IPCC special report cited by commenters as well; in addition to vehicle fuel efficiency, IPCC considers preventing (or reducing) the need for transport,²¹⁵⁹ as “increasingly efficient fleets of vehicles over time . . . does not necessarily limit the driven distance.” (internal citations omitted).²¹⁶⁰

b) Air Quality

This section discusses the health and environmental effects associated with exposure to some of the criteria and air toxic pollutants impacted by the proposed vehicle standards. The agencies note that these impacts are, compared to the impacts on vehicular fuel consumption and CO₂ emissions, small and mixed. CAFE and CO₂ standards directly impact vehicular fuel consumption and CO₂ emissions. Notwithstanding modest indirect impacts, such as impacts on vehicle sales, retention, and mileage accumulation, one can “draw a direct line” between CAFE/CO₂ standards and resultant changes in overall fuel consumption and CO₂ emissions, and these follow the expected trends.

Changes in emissions of criteria pollutants due to these rules will impact air quality. The Clean Air Act (CAA) is the primary federal statute that addresses air quality. Pursuant to its CAA authority, the EPA has established National Ambient Air Quality Standards (NAAQS) for six criteria pollutants: CO, NO₂, ozone, SO₂, particulate matter (PM), and lead. Vehicles do not directly emit ozone, but ozone impacts are evaluated based on emissions of the ozone precursor pollutants nitrogen oxides (NO_x) and volatile organic compounds (VOC). When the measured concentrations of a criteria pollutant in a geographic region are less than those permitted by NAAQS, EPA designates the region as an attainment area for that pollutant; regions where concentrations of criteria pollutants exceed Federal standards are called nonattainment areas. Former nonattainment areas that are now in compliance with NAAQS are designated as attainment areas and are commonly referred to as maintenance areas. Each state with a nonattainment area is required to develop and implement a State Implementation Plan (SIP) documenting how the region will reach attainment levels within periods specified in the CAA. For maintenance areas, the SIP must document how the State intends to maintain compliance with NAAQS. When EPA changes a NAAQS, each State must revise its SIP to address how it plans to attain the new standard. In addition to analyzing criteria pollutants, the agencies considered hazardous air pollutants emitted from vehicles that are known or suspected to cause cancer or other serious health and environmental impacts and are referred to as mobile source air toxics, as further discussed in this section. [Table II-169](#) ~~Table I-26~~ below provides an overview of criteria pollutants and mobile source air toxics with a high level overview of health effects. See further within this section for details on the pollutants and toxics.

Pollutant	Health Effects
Particulate Matter	PM is a generic term for a broad class of chemically and physically diverse substances that exist as discrete particles. PM includes dust, dirt, soot, smoke, and liquid droplets directly emitted into the air, as well as particles formed in the atmosphere by condensation or by the transformation of emitted gases such as NO _x , SO _x , and VOCs. Fine particles are produced primarily by combustion processes and by these atmospheric transformations of emitted gases. PM can damage lung tissue, aggravate existing respiratory and cardiovascular diseases, alter the body's defense systems against foreign materials, and cause cancer and premature death.
Ozone	Ozone is a photochemical oxidant and the major component of smog. Ozone is not emitted directly into the air, but is formed through complex chemical reactions among precursor emissions of VOCs and NO _x . Ground-level ozone causes health problems because it irritates the mucous membranes, damages lung tissue, reduces lung function, and sensitizes the lungs to other irritants.
Nitrogen Dioxide	NO ₂ , one of the oxides of nitrogen formed by high-temperature combustion (as in vehicle engines) of nitrogen and oxygen, is a reddish-brown, highly reactive gas. NO ₂ can irritate the lungs and mucous membranes, aggravate asthma, cause bronchitis and pneumonia, and reduce resistance to respiratory infections.
Sulfur Dioxide	SO ₂ , one of various oxides of sulfur, is a gas formed from combustion of fuels containing sulfur. Most SO ₂ emissions are produced by stationary sources such as power plants. SO ₂ is also formed when gasoline is extracted from crude oil in petroleum refineries and in other industrial processes. High concentrations of SO ₂ cause severe respiratory distress (difficulty breathing), irritate the upper respiratory tract, and aggravate existing respiratory and cardiovascular disease.
Carbon Monoxide	CO is a colorless, odorless, poisonous gas produced by incomplete combustion of carbon in fuels. When CO enters the bloodstream, it acts as an asphyxiant by reducing the delivery of oxygen to the body's organs and tissues. It can affect the central nervous system and impair the brain's ability to function properly.
Mobile Source Air Toxics (including benzene, 1,3-butadiene, formaldehyde, acetaldehyde, acrolein, polycyclic organic matter, and naphthalene)	Mobile source air toxics are hazardous air pollutants that can cause cancer or other serious health effects.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The CAA requires the EPA to review periodically the NAAQS and the supporting science, and to revise the standards as appropriate.²¹⁶¹ Schedules for recently completed and ongoing reviews are summarized here. In February 2019, the EPA issued a decision to retain the existing primary NAAQS for SO₂.²¹⁶² For the ongoing reviews of the NAAQS for PM and ozone, the EPA intends to issue proposed decisions in early 2020 and final decisions in late 2020.

Nationally, levels of PM_{2.5}, ozone, NO₂, SO₂, CO and air toxics have declined significantly in the last 30 years. However, as of January 31, 2020, more than 130 million people lived in counties designated nonattainment for one or more of the NAAQS, and this figure does not include the people living in areas with a risk of exceeding a NAAQS in the future. Many Americans continue to be exposed to ambient concentrations of air toxics at levels which have the potential to cause adverse health effects. In addition, populations who live, work, or attend school near major roads experience elevated exposure concentrations to a wide range of air pollutants. As discussed in the FEIS, concentrations of many air pollutants are elevated near high-traffic roadways. If minority populations and low-income populations disproportionately live near such roads, then an issue of environmental justice (EJ) may be present. Comments were received from multiple entities expressing concern about emissions and EJ communities. The agencies considered EJ when considering the effects of this rule; EJ considerations and EJ-related comments received on the NPRM and DEIS are discussed in Section X and the FEIS.

Total emissions from on-road mobile sources (highway vehicles) have declined dramatically since 1970 because of pollution controls on vehicles and regulation of the chemical content of fuels, despite continuing increases in vehicle miles traveled (VMT). From 1970 to 2016, emissions from on-road mobile sources declined 89 percent for CO, 71 percent for NO_x, 59 percent for PM_{2.5}, 40 percent for PM₁₀, 93 percent for SO₂, and 90 percent for VOCs.²¹⁶³ The figure below further shows the highway vehicle emissions trends that indicate reduced pollutants regulated under NAAQS.

Figure II-5182 - Highway Vehicle Emission Trends, Criteria Pollutants Regulated under NAAQS, 1990-2018

Many commenters expressed concerns about the increase of emissions leading to regions in nonattainment for ozone and particulate matter and concerns regarding the inability to meet the NAAQS. The Center for Biological Diversity et al., and a number of State and local governments and government agencies asserted that State and local jurisdictions would be at jeopardy of becoming nonattainment areas under the proposed rule.²¹⁶⁴ CARB and the joint submission from the States of California and Cities of Oakland stated that the proposed rule would result in “increases in emissions [which] will undermine state implementation plans” and the proposed rule “would create an additional 1.24 tons per day of NOx emissions in the South Coast basin.”²¹⁶⁵ The South Coast Air Quality Management District (SCAQMD) stated “[a]s a regional air quality district, we have limited authority to control emissions from mobile sources, and rely on the Federal government to take action,” and they expressed concern about meeting the

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NAAQS under the proposed rule because, to meet that standard, the Basin would have to “reduce NOx emissions by 45% beyond existing requirements.”²¹⁶⁶

In particular, commenters including PA DEP, the Regional Air Pollution Control Agency (RAPCA), and CARB, expressed the importance of existing CAFE standards in meeting the NAAQS.²¹⁶⁷ The Northeast States for Coordinated Air Use Management (NESCAUM) also asserted that regulation and reduction of GHG was necessary to meet the NAAQS, and “[o]ur states recognize the urgent need to reduce GHG emissions across all sectors of our economy.”²¹⁶⁸ Similarly, the agencies from Minnesota stated that “[t]he existing standards are critical for states to attain and maintain the NAAQS because vehicles account for about 24% of Minnesota’s overall air pollution emissions.”²¹⁶⁹ The Pima County Department of Environmental Quality stated that “[f]reezing emission reductions for six years could put this region in jeopardy of being designated as non-attainment of the ozone standard and impact the health of many of our most vulnerable residents.”²¹⁷⁰ The Washington State Department of Ecology stated that increases in NOx and VOC would increase ozone levels in two areas at risk of ozone nonattainment in the Puget Sound and the Tri-Cities.²¹⁷¹ The Pennsylvania Department of Environmental Protection stated “[r]emoving currently realized emissions reductions and forgoing future achievable emissions reductions may make it more difficult for areas to attain and maintain the NAAQS. PADEP relies on emission reductions from mobile sources as part of its SIP planning to attain and maintain the NAAQS.”²¹⁷² The North Carolina Department of Environmental Quality asserted that based on modeling analysis conducted by NCDEQ, “we believe that the fleet changes predicted by the CAFE modeling would lead to emissions increases that would interfere with the ability of some ozone maintenance areas to meet transportation conformity budgets and maintain compliance with the NAAQS.”²¹⁷³

Many State commenters also expressed concern about their ability to conform with their State Implementation Plan (SIP) after this rule, as the Federal vehicle emissions standards previously set were incorporated into the SIPs and a rollback could result in further increased emissions.²¹⁷⁴ CARB stated that its “2016 SIP calls for reducing NOx emissions by approximately 6 tons per day,” and according to CARB, the proposed rule would not allow California to achieve its South Coast SIP commitments without dramatic countermeasures to reduce emissions elsewhere.²¹⁷⁵ Similarly, other agencies expressed concern about SIP requirements, such as PA DEP, who stated that “[b]y flatlining emissions standards at the MY 2020 level, the agencies’ Proposed Rule increases vehicle emissions. The Proposed Rule would interfere with Pennsylvania’s SIP planning requirements.”²¹⁷⁶

The commenters expressed concerns that this final rule will present challenges in fulfilling existing SIP requirements and in attaining or maintaining the NAAQS, resulting in the need for emission reductions to offset increases due to this rule. This final rulemaking predominantly addresses fuel economy and CO₂ emissions of the light-duty vehicle fleet. It does not affect EPA's Tier 3 vehicle and gasoline (Tier 3) standards or California's low emission vehicle III (LEV III) emission standards. Tier 3 and LEV III regulations are predominantly responsible for regulating criteria pollutant emissions (e.g. NO_x, VOCs, and carbon monoxide) from light-duty vehicles. While this final rulemaking will result in increases in the amount of gasoline produced, the number of vehicle re-fueling events and emissions of certain criteria pollutants and precursors the emissions impact will vary from area to area depending on factors such as the composition of the local vehicle fleet and the amount of gasoline produced in the area. We expect that states will evaluate any adverse emissions or air quality impacts that result from the finalization of this rule in the context of state implementation plan development for relevant NAAQS, such as the relevant ozone and PM_{2.5} NAAQS.

CARB, the joint submission from the States of California and Cities of Oakland, and other commenters also stated that the rulemaking "fails to meet the general conformity requirements under the Clean Air Act."²¹⁷⁷ Similarly, the Center for Biological Diversity, et al., stated "it is highly unlikely that the Proposal would not violate general conformity."²¹⁷⁸ The states and cities expressed that the General Conformity rule applies to this action because "[f]irst, an increase in criteria pollutants is reasonably foreseeable as the agencies quantified those emissions as part of this rulemaking. Second, the agencies can practically control those emissions as they possess ultimate regulatory authority over standards that govern vehicle operation."²¹⁷⁹ CARB stated "NHTSA's determination regarding its own conformity obligations... does not address conformity-related obligations EPA may have that flow from the joint rulemaking."²¹⁸⁰ SCAQMD similarly stated that "EPA counts as a federal agency that must comply with general conformity requirements. The proposal leaves unclear whether EPA also determined its actions comply with the general conformity requirements under 40 C.F.R. § 93.150 and general conformity SIP revisions allowed under 40 C.F.R. § 51.851."²¹⁸¹ SCAQMD concluded that EPA must make its own conformity determination, "and it is not clear that EPA can rely on NHTSA's analysis given its dissimilar position in having continuing program responsibility over mobile source emissions."²¹⁸²

EPA and NHTSA disagree with the commenters that this rule is subject to the CAA section 176(c) conformity requirement and the General Conformity regulations. A General Conformity evaluation is required for a general Federal action proposed to occur within specific nonattainment or maintenance areas. For a General Conformity evaluation to be necessary, the action must cause emissions of the criteria and precursor pollutants for which the areas are nonattainment or maintenance, and the emissions must originate within those areas. Further, the evaluation would require a demonstration that the action conforms to a specific State Implementation Plan's strategy for air pollution prevention and control applicable to the nonattainment and maintenance areas. In addition, any mitigation or offsets required to demonstrate

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

conformity may require written commitments that must be fulfilled, and offsets must occur during the same calendar year as the emission increases from the action.

While the EPA established the framework of methods and procedures that Federal agencies must follow when General Conformity applies to their actions, it is the responsibility of each Federal agency to prepare its own General Conformity evaluation for actions the agency supports, funds, permits or approves. When the EPA functions as a lead agency for actions that are subject to General Conformity, such as water projects, and the agency may issue permits or approve actions that require a General Conformity evaluation, EPA is responsible for and sometimes is required to prepare its own General Conformity evaluation. For the reasons specified here and in Section X.E.2, a General Conformity evaluation is not necessary for either agency.

As stated in section 4.1.1.4 of DEIS, we do not believe the proposed rule would result in either direct or indirect emissions as defined for General Conformity at 40 CFR § 93.152 or as required for applicability of the rule under section 93.153(b). Furthermore, as described in the proposal, emissions from operation of vehicles produced during the model years covered by this rule, while reasonably foreseeable, cannot be quantified with any certainty in any particular nonattainment or maintenance area. In addition, while the emissions rates from MY 2021-2026 vehicles are projected for future years in this rule, neither NHTSA nor EPA has control over where, when or how many of the vehicles will operate during a given future year or within a certain geographical area. Therefore, the emissions are not quantifiable. Furthermore, the General Conformity applicability analysis requires an analytical comparison of the emissions from MY 2021-2026 vehicles in some specific nonattainment or maintenance area in a specific future year, to the emissions projected from the operation of vehicles produced in other model years that would otherwise operate in that same area in the same future year. Without the identity of the future year vehicle fleet by type/make/model (which depends on a specific nonattainment or maintenance location and year), the net emissions, or total of direct and indirect emissions, cannot be quantified. Thus, this rule, in and of itself, is not subject to a General Conformity evaluation.

CARB stated that this rulemaking would, if finalized, invalidate the model underlying California's SIPs (the EMFAC 2014 model), which would result in the SIPs being disapproved by EPA.²¹⁸³ CARB expressed further concern that as a result of the Clean Air Act's conformity requirements, this disapproval would put significant limits on new RTPs, TIPS, or regionally significant transportation projects being adopted or approved in California.²¹⁸⁴

The commenter expressed the opinion that if this rule is finalized, EPA would disapprove its SIPs because its on-road emission factor model (EMFAC) would be invalidated. The commenter also opined that such disapprovals would limit the ability of metropolitan planning organizations in California to make transportation conformity determinations for metropolitan transportation plans, transportation improvement programs and certain transportation projects. It is premature to assume that EPA will disapprove SIPs because they are based on EMFAC2014 or EMFAC2017. EPA will evaluate and address, as appropriate, the impact of the SAFE action on future SIP approval actions EMFAC2014 and EMFAC2017 remain approved emission factor models for SIPs and transportation conformity analyses in California. EPA is aware that California released adjustment factors to be applied to EMFAC2014 and EMFAC2017 model results to account for impacts of the SAFE Part 1 rule for on-road criteria pollutant emissions from light-duty vehicles.

²¹⁸⁴ CARB, NHTSA-2018-0067-11873.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

EPA will work with CARB and DOT on the appropriate implementation of federal requirements based on current and available information.

Because passenger cars and light trucks are subject to gram-per-mile emissions standards for criteria pollutants, more fuel-efficient (and, correspondingly, less CO₂-intensive) vehicles are not, from the standpoint of air quality, “cleaner” vehicles. Therefore, to the extent that CAFE/CO₂ standards lead to changes in overall quantities of vehicular emissions that impact air quality, these are dominated by induced changes in highway travel. Changes in overall fuel consumption do lead to changes in emissions from “upstream” processes involved in supplying fuel to vehicles. Depending on how total vehicular emissions and total upstream emissions change in response to less stringent standards, overall emissions could increase or decrease. While small in magnitude, net impacts could also vary considerably among different geographic areas. In other words, CAFE and CO₂ standards impact fuel consumption and CO₂ emissions in ways that are direct and unambiguous, and impact air quality in ways that are indirect and ambiguous.

The following sections, included in prior rules setting fuel economy and CO₂ standards and updated based on EPA’s latest scientific assessments, describe the criteria and air toxics considered in this rule, and their health and environmental effects. Additionally, the section that follows describes how the estimated effects of each pollutant were modeled in this rulemaking. Section P07 discusses the interactions between upstream, tailpipe, and highway travel that result in the net emissions of criteria and air toxic pollutants estimated as a result of this rule.

(I) *Particulate Matter*

(a) *Background*

Particulate matter (PM) is a complex mixture of solid particles and liquid droplets distributed among numerous atmospheric gases which interact with solid and liquid phases. Particles range in size from those smaller than 1 nanometer (10⁻⁹ meter) to over 100 micrometers (μm, or 10⁻⁶ meter) in diameter (for reference, a typical strand of human hair is 50-70 μm in diameter and a grain of fine beach sand is about typically 90 μm in diameter). Atmospheric particles can be grouped into several classes according to their aerodynamic and physical sizes. Generally, the three broad classes of particles include ultrafine particles (UFPs, generally considered as particulates with a diameter less than or equal to 0.1 μm [typically based on physical size, thermal diffusivity or electrical mobility]), “fine” particles (PM_{2.5}; particles with a nominal mean aerodynamic diameter less than or equal to 2.5 μm), and “thoracic” particles (PM₁₀; particles with a nominal mean aerodynamic diameter less than or equal to 10 μm). Particles that fall within the size range between PM_{2.5} and PM₁₀ are referred to as “thoracic coarse particles” (PM_{10-2.5} particles with a nominal mean aerodynamic diameter greater than 2.5 μm and less than or equal to 10 μm). EPA currently has standards that regulate PM_{2.5} and PM₁₀.²¹⁸⁵

Most particles are found in the lower troposphere, where they can have residence times ranging from a few hours to weeks. Particles are removed from the atmosphere by wet deposition, such as when they are carried by rain or snow, or by dry deposition, when particles settle out of suspension due to gravity.

²¹⁸⁵ Regulatory definitions of PM size fractions and information on reference and equivalent methods for measuring PM in ambient air are provided in 40 CFR Parts 50, 53, and 58. With regard to national ambient air quality standards (NAAQS) which provide protection against health and welfare effects, the 24-hour PM₁₀ standard provides protection against effects associated with short-term exposure to thoracic coarse particles (i.e. PM_{10-2.5}).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Atmospheric lifetimes are generally longest for PM_{2.5}, which often remains in the atmosphere for days to weeks before being removed by wet or dry deposition.²¹⁸⁶ In contrast, atmospheric lifetimes for UFP and PM_{10–2.5} are shorter. Within hours, UFP can undergo coagulation and condensation that lead to formation of larger particles in the accumulation mode, or can be removed from the atmosphere by evaporation, deposition, or reactions with other atmospheric components. PM_{10–2.5} are also generally removed from the atmosphere within hours, through wet or dry deposition.²¹⁸⁷

Particulate matter consists of both primary and secondary particles. Primary particles are emitted directly from sources, such as combustion-related activities (e.g., industrial activities, motor vehicles, biomass burning), while secondary particles are formed through atmospheric chemical reactions of gaseous precursors (e.g., sulfur oxides (SO_x), nitrogen oxides (NO_x) and volatile organic compounds (VOCs) and ammonia). From 2000 to 2017, national annual average PM_{2.5} concentrations have declined by over 40%,²¹⁸⁸ largely reflecting reductions in emissions of precursor gases.

(b) *Health Effects of PM*

Scientific evidence spanning animal toxicological, controlled human exposure, and epidemiologic studies shows that exposure to ambient PM is associated with a broad range of health effects. These health effects are discussed in detail in the Integrated Science Assessment for Particulate Matter (PM ISA), which was finalized in December 2019.²¹⁸⁹ The PM ISA summarizes the health effects evidence for short- and long-term exposures to PM_{2.5}, PM_{10–2.5}, and ultrafine particles. The PM ISA concludes that human exposures to ambient PM_{2.5} are associated with a number of adverse health effects and characterizes the causal nature of relationships between PM exposure and broad health categories (e.g., cardiovascular effects, respiratory effects, etc.) using a weight-of-evidence approach.²¹⁹⁰ The discussion below highlights the PM ISA's conclusions pertaining to the health effects associated with both short- and long-term PM exposures. Further discussion of health effects associated with PM can also be found in the 2020 Policy Assessment for the review of the PM NAAQS.²¹⁹¹

²¹⁸⁷ U.S. EPA. Integrated Science Assessment (ISA) for Particulate Matter (Final Report, 2019). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-19/188, 2019. Table 2-1.

²¹⁸⁸ See <https://www.epa.gov/air-trends/particulate-matter-pm25-trends> and <https://www.epa.gov/air-trends/particulate-matter-pm25-trends#pmnat> for more information

²¹⁸⁹ U.S. EPA. Integrated Science Assessment (ISA) for Particulate Matter (Final Report, 2019). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-19/188, 2019.

²¹⁹⁰ The causal framework draws upon the assessment and integration of evidence from across scientific disciplines, spanning atmospheric chemistry, exposure, dosimetry, and health effects studies (i.e., epidemiologic controlled human exposure and animal toxicological studies), and assess the related uncertainties and limitations that ultimately influence our understanding of the evidence. This framework employs a five-level hierarchy that classifies the overall weight-of-evidence with respect to the causal nature of relationships between criteria pollutant exposures and health and welfare effects using the following categorizations: causal relationship; likely to be causal relationship; suggestive of but not sufficient to infer, a causal relationship; inadequate to infer the presence or absence of a causal relationship; and not likely to be a causal relationship (U.S. EPA. (2019). Integrated Science Assessment for Particulate Matter (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-19/188, Section P. 3.2.3).

²¹⁹¹ U.S. EPA. Policy Assessment (PA) for the Review of the National Ambient Air Quality Standards for Particulate Matter (Final Report, 2020). U.S. Environmental Protection Agency, Washington, DC, EPA/452/R-20/002, 2020.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

EPA has concluded that recent evidence in combination with evidence evaluated in the 2009 PM ISA supports a “causal relationship” between both long- and short-term exposures to PM_{2.5} and premature mortality and cardiovascular effects and a “likely to be causal relationship” between long- and short-term PM_{2.5} exposures and respiratory effects. Additionally, recent experimental and epidemiologic provide evidence supporting a “likely to be causal relationship” between long-term PM_{2.5} exposure and nervous system effects and long-term PM_{2.5} exposure and cancer. Health effect categories for which remaining uncertainties and limitations in the evidence base exist, resulted in a conclusion of “suggestive of, but not sufficient to infer, a causal relationship” for long-term PM_{2.5} exposure and reproductive and developmental effects (i.e., male/female reproduction and fertility; pregnancy and birth outcomes) and metabolic effects; and short-term PM_{2.5} exposure and nervous system effects and metabolic effects.

As discussed extensively in the 2019 PM ISA, recent studies continue to support and extend the evidence base linking short- and long-term PM_{2.5} exposures and premature mortality.²¹⁹² For short-term PM_{2.5} exposure, recent multi-city studies, in combination with single- and multi-city studies evaluated in the 2009 PM ISA, provide evidence of consistent, positive associations across studies conducted in different geographic locations, populations with different demographic characteristics, and studies using different exposure assignment techniques. Additionally, the consistent and coherent evidence across scientific disciplines for cardiovascular morbidity, particularly ischemic event s and heart failure, and to a lesser degree for respiratory morbidity, with the strongest evidence for exacerbations of chronic obstructive pulmonary disease (COPD) and asthma, provide biological plausibility for cause-specific mortality and ultimately total mortality.

In addition to re-analyses and extensions of the American Cancer Society (ACS) and Harvard Six Cities (HSC) cohorts, multiple new cohort studies conducted in the U.S. and Canada consisting of people employed in a specific job (e.g., teacher, nurse), and that apply different exposure assignment techniques provide evidence of positive associations between long -term PM_{2.5} exposure and mortality. Biological plausibility for mortality due to long-term PM_{2.5} exposure is provided by the coherence of effects across scientific disciplines for cardiovascular morbidity, particularly for coronary heart disease (CHD), stroke and atherosclerosis, and for respiratory morbidity, particularly for the development of COPD. Additionally, recent studies provide evidence indicating that as long -term PM_{2.5} concentrations decrease there is an increase in life expectancy.

A large body of recent studies examining both short- and long-term PM_{2.5} exposure and cardiovascular effects supports and extend s the evidence base evaluated in the 2009 PM ISA. Some of the strongest evidence from both experimental and epidemiologic studies examining short-term PM_{2.5} exposures are for ischemic heart disease (IHD) and heart failure. The evidence for cardiovascular effects is coherent across studies of short-term PM_{2.5} exposure that have observed associations with a continuum of effects ranging from subtle changes in indicators of cardiovascular health to serious clinical events, such as increased emergency department visits and hospital admissions due to cardiovascular disease and cardiovascular mortality. For long- term PM_{2.5} exposure, there is strong and consistent epidemiologic evidence of a relationship with cardiovascular mortality. This evidence is supported by epidemiologic and animal toxicological studies demonstrating a range or cardiovascular effects including coronary heart

²¹⁹² U.S. EPA Integrated Science Assessment (ISA) for Particulate Matter (Final Report, 2019). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-19/188, 2019.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

disease, stroke, impaired heart function, and sub clinical markers (e.g., coronary artery calcification, atherosclerotic plaque progression), which collectively provide coherence and biological plausibility.

Recent studies continue to provide evidence of a relationship between both short- and long-term PM_{2.5} exposure and respiratory effects. Epidemiologic and animal toxicological studies examining short-term PM_{2.5} exposure provide consistent evidence of asthma and COPD exacerbations, in children and adults, respectively. This evidence is supported by epidemiologic studies examining asthma and COPD emergency department visits and hospital admissions, as well as, respiratory mortality. Epidemiologic studies conducted in the U.S. and abroad provide evidence of a relationship between long-term PM_{2.5} exposure and respiratory effects, including consistent changes in lung function and lung function growth rate, increased asthma incidence, asthma prevalence, and wheeze in children; acceleration of lung function decline in adults; and respiratory mortality. The epidemiologic evidence is supported by animal toxicological studies, which provide coherence and biological plausibility for a range of effects including impaired lung development, decrements in lung function growth, and asthma development.

Since the 2009 PM ISA, a growing body of scientific evidence examined the relationship between long-term PM_{2.5} exposure and nervous system effects, resulting in the first time a causality determination has been made for this health effects category. Epidemiologic studies provide consistent evidence for cognitive decline and impairment along with a decrease in brain volume in adults. The effects observed in epidemiologic studies are supported by animal toxicological studies demonstrating effects on the brain of adult animals including inflammation, morphologic changes, and neurodegeneration of specific regions of the brain.

Building off the decades of research demonstrating mutagenicity, DNA damage, and endpoints related to genotoxicity due to whole PM exposures, recent experimental and epidemiologic studies focusing specifically on PM_{2.5} provide evidence of a relationship between long-term PM_{2.5} exposure and cancer. Epidemiologic studies examining long-term PM_{2.5} exposure and lung cancer incidence and mortality provide evidence of generally positive associations in cohort studies spanning different populations, locations, and exposure assignment techniques. Additionally, there is evidence of positive associations in analyses limited to never smokers. The epidemiologic evidence is supported by both experimental and epidemiologic evidence of genotoxicity, epigenetic effects, carcinogenic potential, and that PM_{2.5} exhibits several characteristics of carcinogens, which collectively provides biological plausibility for cancer development.

For the additional health effects categories evaluated for PM_{2.5} in the 2019 PM ISA, experimental and epidemiologic studies provide limited and/or inconsistent evidence of a relationship with PM_{2.5} exposure. As a result, the 2019 PM ISA concluded the evidence is “suggestive of, but not sufficient to infer a causal relationship” for short-term PM_{2.5} exposure and metabolic effects and nervous system effects, and long-term PM_{2.5} exposures and metabolic effects as well as reproductive and developmental effects.

In addition to evaluating the health effects attributed to short- and long-term exposure to PM_{2.5}, the 2019 PM ISA also conducted an extensive evaluation as to whether specific components or sources of PM_{2.5} are more strongly related with specific health effects than PM_{2.5} mass. An evaluation of those studies resulted in the 2019 PM ISA concluding that “many PM_{2.5} components and sources are associated with many

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

health effects, and the evidence does not indicate that any one source or component is consistently more strongly related to health effects than PM_{2.5} mass.”²¹⁹³

For both PM_{10–2.5} and UFPs, for all health effects categories evaluated, the 2019 PM ISA concluded the evidence was “suggestive of, but not sufficient to infer a causal relationship” or “inadequate to determine the presence or absence of a causal relationship.” For PM_{10–2.5} although a Federal Reference Method (FRM) was instituted in 2011 to measure PM_{10–2.5} concentrations nationally, the causality determination s reflect that the same uncertainty identified in the 2009 PM ISA with respect to the method used to estimate PM_{10–2.5} concentrations in epidemiologic studies persists. Specifically, across epidemiologic studies, different approaches are used to estimate PM_{10–2.5} concentrations (e.g., direct measurement of PM_{10–2.5}, difference between PM₁₀ and PM_{2.5} concentrations), and it remains unclear how well correlated PM_{10–2.5} concentrations are both spatially and temporally across the different methods used.

For UFPs, the uncertainty in the evidence for the health effect categories evaluated across experimental and epidemiologic studies reflects the inconsistency in the exposure metric used (i.e., particle number concentration, surface area concentration, mass concentration) as well as the size fractions examined, with epidemiologic studies often focusing on particles 0.1 µm and less and experimental studies of ten examining particles up to 0.3 µm. Additionally, due to the lack of a monitoring network there is limited information on the spatial and temporal variability of UFPs within the U.S., as well as population exposures to UFPs, which adds uncertainty to epidemiologic study results.

The 2019 PM ISA cites extensive evidence indicating that “both the general population as well as specific populations and lifestyles are at risk for PM_{2.5}-related health effects.”^{2194,2195} For example, in support of its “causal” and “likely to be causal” determinations, the ISA cites substantial evidence for (1) PM-related mortality and cardiovascular effects in older adults; (2) *PM-related cardiovascular effects in people with pre-existing cardiovascular disease*; (3) *PM-related cardiovascular effects in people with pre-existing respiratory disease, particularly asthma exacerbations in children*; and (4) PM-related impairments in lung function growth and asthma development in children. The ISA additionally notes that *stratified analyses i.e., analyses that directly compare PM-related health effects across groups* provide strong evidence for racial and ethnic differences in PM_{2.5} and in PM_{2.5}-related health risk. Such analyses indicate that minority populations such as Hispanic and non-Hispanic black populations are at increased risk for PM_{2.5}-related health effects. Stratified analyses focusing on other groups also suggest that populations with pre-existing cardiovascular or respiratory disease, populations that are overweight or obese, populations that have particular genetic variants, populations that are of low socioeconomic status, and current/former smokers could be at increased risk for PM_{2.5}-related adverse health effects.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(c) *Current Concentrations*

There are two primary NAAQS for PM_{2.5}: an annual standard (12.0 micrograms per cubic meter (µg/m³)) set in 2012 and a 24-hour standard (35 µg/m³) set in 2006, and two secondary NAAQS for PM_{2.5}: an annual standard (15.0 µg/m³) set in 1997 and a 24-hour standard (35 µg/m³) set in 2006.²¹⁹⁶

There are many areas of the country that are currently in nonattainment for the annual and 24-hour primary PM_{2.5} NAAQS. As of January 31, 2020, more than 19 million people lived in the 4 areas that are designated as nonattainment for the 1997 annual PM_{2.5} NAAQS. These PM_{2.5} nonattainment areas are comprised of 14 full or partial counties. As of January 31, 2020, 6 areas are designated as nonattainment for the 2012 annual PM_{2.5} NAAQS; these areas are composed of 16 full or partial counties with a population of more than 20 million. As of January 31, 2020, 14 areas are designated as nonattainment for the 2006 24-hour PM_{2.5} NAAQS; these areas are composed of 41 full or partial counties with a population of more than 31 million. In total, there are currently 17 PM_{2.5} nonattainment areas with a population of more than 32 million people.

The EPA has already adopted many mobile source emission control programs that are expected to reduce ambient PM concentrations. As a result of these and other federal, state and local programs, the number of areas that fail to meet the PM_{2.5} NAAQS in the future is expected to decrease. However, even with the implementation of all current state and federal regulations, there are projected to be counties violating the PM_{2.5} NAAQS well into the future.

(2) *Ozone*

(a) *Background*

Ground-level ozone pollution is typically formed through reactions involving VOC and NO_x in the lower atmosphere in the presence of sunlight. These pollutants, often referred to as ozone precursors, are emitted by many types of sources, such as highway and nonroad motor vehicles and engines, power plants, chemical plants, refineries, makers of consumer and commercial products, industrial facilities, and smaller area sources.

The science of ozone formation, transport, and accumulation is complex. Ground-level ozone is produced and destroyed in a cyclical set of chemical reactions, many of which are sensitive to temperature and sunlight. When ambient temperatures and sunlight levels remain high for several days and the air is relatively stagnant, ozone and its precursors can build up and result in more ozone than typically occurs on a single high-temperature day. Ozone and its precursors can be transported hundreds of miles downwind from precursor emissions, resulting in elevated ozone levels even in areas with low local VOC or NO_x emissions.

²¹⁹⁶ The EPA is currently reviewing the PM NAAQS and anticipates completing this review in late 2020 Available at <https://www.epa.gov/naaqs/particulate-matter-pm-air-quality-standards>).

This section provides a summary of the health effects associated with exposure to ambient concentrations of ozone.²¹⁹⁷ The information in this section is based on the information and conclusions in the February 2013 Integrated Science Assessment for Ozone (Ozone ISA), which formed the basis for EPA's revision to the primary and secondary standards in 2015.²¹⁹⁸ The Ozone ISA concludes that human exposures to ambient concentrations of ozone are associated with a number of adverse health effects and characterizes the weight of evidence for these health effects.²¹⁹⁹ The discussion below highlights the Ozone ISA's conclusions pertaining to health effects associated with both short-term and long-term periods of exposure to ozone.

For short-term exposure to ozone, the Ozone ISA concludes that respiratory effects, including lung function decrements, pulmonary inflammation, exacerbation of asthma, respiratory-related hospital admissions, and mortality, are causally associated with ozone exposure. It also concludes that cardiovascular effects, including decreased cardiac function and increased vascular disease, and total mortality are likely to be causally associated with short-term exposure to ozone and that evidence is suggestive of a causal relationship between central nervous system effects and short-term exposure to ozone.

For long-term exposure to ozone, the Ozone ISA concludes that respiratory effects, including new onset asthma, pulmonary inflammation and injury, are likely to be causally related with ozone exposure. The Ozone ISA characterizes the evidence as suggestive of a causal relationship for associations between long-term ozone exposure and cardiovascular effects, reproductive and developmental effects, central nervous system effects and total mortality. The evidence is inadequate to infer a causal relationship between chronic ozone exposure and increased risk of lung cancer.

Finally, inter-individual variation in human responses to ozone exposure can result in some groups being at increased risk for detrimental effects in response to exposure. In addition, some groups are at increased risk of exposure due to their activities, such as outdoor workers or children. The Ozone ISA identified several groups that are at increased risk for ozone-related health effects. These groups are people with asthma, children and older adults, individuals with reduced intake of certain nutrients (i.e., Vitamins C and E), outdoor workers, and individuals having certain genetic variants related to oxidative metabolism or inflammation. Ozone exposure during childhood can have lasting effects through adulthood. Such effects include altered function of the respiratory and immune systems. Children absorb higher doses (normalized to lung surface area) of ambient ozone, compared to adults, due to their increased time spent outdoors, higher ventilation rates relative to body size, and a tendency to breathe a greater fraction of air through the mouth. Children also have a higher asthma prevalence compared to adults.

²¹⁹⁷ Human exposure to ozone varies over time due to changes in ambient ozone concentration and because people move between locations which have notable different ozone concentrations. Also, the amount of ozone delivered to the lung is not only influenced by the ambient concentrations but also by the individuals breathing route and rate.

²¹⁹⁸ U.S. EPA. Integrated Science Assessment of Ozone and Related Photochemical Oxidants (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-10/076F, 2013. The ISA is available at <http://cfpub.epa.gov/ncea/isa/recordisplay.cfm?deid=247492#Download>.

²¹⁹⁹ The ISA evaluates evidence and draws conclusions on the causal nature of relationship between relevant pollutant exposures and health effects, assigning one of five "weight of evidence" determinations: causal relationship, likely to be a causal relationship, suggestive of, but not sufficient to infer, a causal relationship, inadequate to infer a causal relationship, and not likely to be a causal relationship. For more information on these levels of evidence, please refer to Table II in the Preamble of the ISA.

(c) *Current Concentrations*

The primary and secondary NAAQS for ozone are 8-hour standards with a level of 0.07 ppm. The most recent revision to the ozone standards was in 2015; the previous 8-hour ozone primary standard, set in 2008, had a level of 0.075 ppm.²²⁰⁰ As of January 31, 2020, there were 36 ozone nonattainment areas for the 2008 ozone NAAQS, composed of 153 full or partial counties, with a population of more than 99 million. As of January 31, 2020, there were 51 ozone nonattainment areas for the 2015 ozone NAAQS, composed of 206 full or partial counties, with a population of more than 122 million. In total, there are currently 59 ozone nonattainment areas with a population of more than 127 million people.

States with ozone nonattainment areas are required to take action to bring those areas into attainment. The attainment date assigned to an ozone nonattainment area is based on the area's classification. The attainment dates for areas designated nonattainment for the 2008 8-hour ozone NAAQS are in the 2015 to 2032 timeframe, depending on the severity of the problem in each area. Nonattainment area attainment dates associated with areas designated for the 2015 NAAQS will be in the 2021-2038 timeframe, depending on the severity of the problem in each area.

EPA has already adopted many emission control programs that are expected to reduce ambient ozone levels. As a result of these and other federal, state and local programs, 8-hour ozone levels are expected to improve in the future. However, even with the implementation of all current state and federal regulations, there are projected to be counties violating the ozone NAAQS well into the future.

(3) *Nitrogen Oxides*

(a) *Background*

Oxides of nitrogen (NO_x) refers to nitric oxide and nitrogen dioxide (NO₂). For the NO_x NAAQS, NO₂ is the indicator. Most NO₂ is formed in the air through the oxidation of nitric oxide (NO) emitted when fuel is burned at a high temperature. NO_x is also a major contributor to secondary PM_{2.5} formation. NO_x and VOC are the two major precursors of ozone.

(b) *Health Effects of Nitrogen Oxides*

The most recent review of the health effects of oxides of nitrogen completed by EPA can be found in the 2016 Integrated Science Assessment for Oxides of Nitrogen - Health Criteria (Oxides of Nitrogen ISA).²²⁰¹ The primary source of NO₂ is motor vehicle emissions, and ambient NO₂ concentrations tend to be highly correlated with other traffic-related pollutants. Thus, a key issue in characterizing the causality of NO₂-health effect relationships was evaluating the extent to which studies supported an effect of NO₂ that is independent of other traffic-related pollutants. EPA concluded that the findings for asthma exacerbation integrated from epidemiologic and controlled human exposure studies provided evidence that is sufficient to infer a causal relationship between respiratory effects and short-term NO₂ exposure. The strongest evidence supporting an independent effect of NO₂ exposure comes from controlled human exposure studies demonstrating increased airway responsiveness in individuals with asthma following ambient-relevant NO₂

²²⁰⁰ The EPA is currently reviewing the PM NAAQS and anticipates completing this review in late 2020 Available at (<https://www.epa.gov/naaqs/ozone-o3-air-quality-standards>).

²²⁰¹ U.S. EPA. Integrated Science Assessment for Oxides of Nitrogen – Health Criteria (2016 Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-15/068, 2016.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

exposures. The coherence of this evidence with epidemiologic findings for asthma hospital admissions and ED visits as well as lung function decrements and increased pulmonary inflammation in children with asthma describe a plausible pathway by which NO₂ exposure can cause an asthma exacerbation. The 2016 ISA for Oxides of Nitrogen also concluded that there is likely to be a causal relationship between long-term NO₂ exposure and respiratory effects. This conclusion is based on new epidemiologic evidence for associations of NO₂ with asthma development in children combined with biological plausibility from experimental studies.

In evaluating a broader range of health effects, the 2016 ISA for Oxides of Nitrogen concluded evidence is “suggestive of, but not sufficient to infer, a causal relationship” between short-term NO₂ exposure and cardiovascular effects and mortality and between long-term NO₂ exposure and cardiovascular effects and diabetes, birth outcomes, and cancer. In addition, the scientific evidence is inadequate (insufficient consistency of epidemiologic and toxicological evidence) to infer a causal relationship for long-term NO₂ exposure with fertility, reproduction, and pregnancy, as well as with postnatal development. A key uncertainty in understanding the relationship between these non-respiratory health effects and short- or long-term exposure to NO₂ is copollutant confounding, particularly by other roadway pollutants. The available evidence for non-respiratory health effects does not adequately address whether NO₂ has an independent effect or whether it primarily represents effects related to other or a mixture of traffic-related pollutants.

The 2016 ISA for Oxides of Nitrogen concluded that people with asthma, children, and older adults are at increased risk for NO₂-related health effects. In these groups and life stages, NO₂ is consistently related to larger effects on outcomes related to asthma exacerbation, for which there is confidence in the relationship with NO₂ exposure.

(c) *Current Concentrations*

On April 6, 2018, based on a review of the full body of scientific evidence, EPA issued a decision to retain the current primary NAAQS for NO₂. The EPA has concluded that the current NAAQS are requisite to protect the public health, including the at-risk populations of older adults, children and people with asthma, with an adequate margin of safety. The primary NAAQS for NO₂ are a one-hour standard with a level of 100 ppb, based on the three-year average of 98th percentile of the annual distribution of daily maximum one-hour concentrations, and an annual standard at a level of 53 ppb.

(4) *Sulfur Oxides*

(a) *Background*

Sulfur dioxide (SO₂), a member of the sulfur oxide (SO_x) family of gases, is formed from burning fuels containing sulfur (e.g., coal or oil derived), extracting gasoline from oil, or extracting metals from ore. SO₂ and its gas phase oxidation products can dissolve in water droplets and further oxidize to form sulfuric acid which reacts with ammonia to form sulfates, which are important components of ambient PM.

(b) *Health Effects of SO₂*

This section provides an overview of the health effects associated with SO₂. Additional information on the health effects of SO₂ can be found in the 2017 Integrated Science Assessment for Sulfur Oxides -

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Health Criteria (SO_x ISA).²²⁰² Following an extensive evaluation of health evidence from animal toxicological, controlled human exposure, and epidemiologic studies, the EPA has concluded that there is a causal relationship between respiratory health effects and short-term exposure to SO₂. The immediate effect of SO₂ on the respiratory system in humans is bronchoconstriction. People with asthma are more sensitive to the effects of SO₂, likely resulting from preexisting inflammation associated with this disease. In addition to those with asthma (both children and adults), there is suggestive evidence that all children and older adults may be at increased risk of SO₂-related health effects. In free-breathing laboratory studies involving controlled human exposures to SO₂, respiratory effects have consistently been observed following 5-10 min exposures at SO₂ concentrations \geq 400 ppb in people with asthma engaged in moderate to heavy levels of exercise, with respiratory effects occurring at concentrations as low as 200 ppb in some individuals with asthma. A clear concentration-response relationship has been demonstrated in these studies following exposures to SO₂ at concentrations between 200 and 1000 ppb, both in terms of increasing severity of respiratory symptoms and decrements in lung function, as well as the percentage of individuals with asthma adversely affected. Epidemiologic studies have reported positive associations between short-term ambient SO₂ concentrations and hospital admissions and emergency department visits for asthma and for all respiratory causes, particularly among children and older adults (\geq 65 years). The studies provide supportive evidence for the causal relationship.

For long-term SO₂ exposure and respiratory effects, the EPA has concluded that the evidence is suggestive of a causal relationship. This conclusion is based on new epidemiologic evidence for positive associations between long-term SO₂ exposure and increases in asthma incidence among children, together with animal toxicological evidence that provides a pathophysiologic basis for the development of asthma. However, uncertainty remains regarding the influence of other pollutants on the observed associations with SO₂ because these epidemiologic studies have not examined the potential for copollutant confounding.

Consistent associations between short-term exposure to SO₂ and mortality have been observed in epidemiologic studies, with larger effect estimates reported for respiratory mortality than for cardiovascular mortality. While this finding is consistent with the demonstrated effects of SO₂ on respiratory morbidity, uncertainty remains with respect to the interpretation of these observed mortality associations due to potential confounding by various copollutants. Therefore, the EPA has concluded that the overall evidence is suggestive of a causal relationship between short-term exposure to SO₂ and mortality.

(c) *Current Concentrations*

On February 25, 2019, the EPA announced its decision to retain, without revision, the existing NAAQS for SO_x of 75 ppb, as the annual 99th percentile of daily maximum SO₂ concentrations, averaged over three years (84 FR 9866, March 18, 2019). The existing primary (health-based) standard provides health protection for the at-risk group (people with asthma) against respiratory effects following short-term (e.g., 5-minute) exposures to SO₂ in ambient air. The EPA has been finalizing the initial area designations for the 2010 SO₂ NAAQS in phases and completed designations for most of the country in December 2017. The EPA is under a court order to finalize initial designations by December 31, 2020, for a remaining set of about 50 areas where states have deployed new SO₂ monitoring networks. As of January 31, 2020 there are

²²⁰² U.S. EPA (2017). Integrated Science Assessment (ISA) for Sulfur Oxides. Health Criteria (Final Report). EPA 600/R-17/451. Washington, DC, U.S. EPA.

34 nonattainment areas for the 2010 SO₂ NAAQS. As of January 31, 2020 there also remain eight nonattainment areas for the primary annual SO₂ NAAQS set in 1971.

(5) *Carbon Monoxide*

(a) *Background*

Carbon monoxide is a colorless, odorless gas emitted from combustion processes. Nationally, particularly in urban areas, the majority of CO emissions to ambient air come from mobile sources.²²⁰³

(b) *Health Effects of Carbon Monoxide*

Information on the health effects of CO can be found in the January 2010 Integrated Science Assessment for Carbon Monoxide (CO ISA) associated with the 2010 evaluation of the NAAQS.²²⁰⁴ The CO ISA presents conclusions regarding the presence of causal relationships between CO exposure and categories of adverse health effects. This section provides a summary of the health effects associated with exposure to ambient concentrations of CO, along with the ISA conclusions.²²⁰⁵

Controlled human exposure studies of subjects with coronary artery disease show a decrease in the time to onset of exercise-induced angina (chest pain) and electrocardiogram changes following CO exposure. In addition, epidemiologic studies observed associations between short-term CO exposure and cardiovascular morbidity, particularly increased emergency room visits and hospital admissions for coronary heart disease (including ischemic heart disease, myocardial infarction, and angina). Some epidemiologic evidence is also available for increased hospital admissions and emergency room visits for congestive heart failure and cardiovascular disease as a whole. The CO ISA concludes that a causal relationship is likely to exist between short-term exposures to CO and cardiovascular morbidity. It also concludes that available data are inadequate to conclude that a causal relationship exists between long-term exposures to CO and cardiovascular morbidity.

Animal studies show various neurological effects with in-utero CO exposure. Controlled human exposure studies report central nervous system and behavioral effects following low-level CO exposures, although the findings have not been consistent across all studies. The CO ISA concludes the evidence is suggestive of a causal relationship with both short- and long-term exposure to CO and central nervous system effects.

A number of studies cited in the CO ISA have evaluated the role of CO exposure in birth outcomes such as preterm birth or cardiac birth defects. There is limited epidemiologic evidence of a CO-induced effect on preterm births and birth defects, with weak evidence for a decrease in birth weight. Animal toxicological studies have found perinatal CO exposure to affect birth weight, as well as other developmental

²²⁰³ U.S. EPA (2010). Integrated Science Assessment for Carbon Monoxide (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-09/019F, 2010. Available at <http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=218686>. See Section 2.1.

²²⁰⁴ U.S. EPA (2010). Integrated Science Assessment for Carbon Monoxide (Final Report). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-09/019F, 2010. Available at <http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=218686>.

²²⁰⁵ Personal exposure includes contributions from many sources, and in many different environments. Total personal exposure to CO includes both ambient and nonambient components; and both components may contribute to adverse health effects.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

outcomes. The CO ISA concludes the evidence is suggestive of a causal relationship between long-term exposures to CO and developmental effects and birth outcomes.

Epidemiologic studies provide evidence of associations between short-term CO concentrations and respiratory morbidity such as changes in pulmonary function, respiratory symptoms, and hospital admissions. A limited number of epidemiologic studies considered copollutants such as ozone, SO₂, and PM in two-pollutant models and found that CO risk estimates were generally robust, although this limited evidence makes it difficult to disentangle effects attributed to CO itself from those of the larger complex air pollution mixture. Controlled human exposure studies have not extensively evaluated the effect of CO on respiratory morbidity. Animal studies at levels of 50-100 ppm CO show preliminary evidence of altered pulmonary vascular remodeling and oxidative injury. The CO ISA concludes that the evidence is suggestive of a causal relationship between short-term CO exposure and respiratory morbidity, and inadequate to conclude that a causal relationship exists between long-term exposure and respiratory morbidity.

Finally, the CO ISA concludes that the epidemiologic evidence is suggestive of a causal relationship between short-term concentrations of CO and mortality. Epidemiologic evidence suggests an association exists between short-term exposure to CO and mortality, but limited evidence is available to evaluate cause-specific mortality outcomes associated with CO exposure. In addition, the attenuation of CO risk estimates which was often observed in copollutant models contributes to the uncertainty as to whether CO is acting alone or as an indicator for other combustion-related pollutants. The CO ISA also concludes that there is not likely to be a causal relationship between relevant long-term exposures to CO and mortality.

(c) *Current Concentrations*

There are two primary NAAQS for CO: an 8-hour standard (9 ppm) and a 1-hour standard (35 ppm). The primary NAAQS for CO were retained in August 2011. There are currently no CO nonattainment areas; as of September 27, 2010, all CO nonattainment areas have been redesignated to attainment.

The past designations were based on the existing community-wide monitoring network. EPA made an addition to the ambient air monitoring requirements for CO during the 2011 NAAQS review. Those new requirements called for CO monitors to be operated near roads in Core Based Statistical Areas (CBSAs) of 1 million or more persons (76 FR 54294, August 31, 2011).

(6) *Diesel Exhaust*

(a) *Background*

Diesel exhaust consists of a complex mixture composed of particulate matter, carbon dioxide, oxygen, nitrogen, water vapor, carbon monoxide, nitrogen compounds, sulfur compounds, and numerous low-molecular-weight hydrocarbons. A number of these gaseous hydrocarbon components are individually known to be toxic, including aldehydes, benzene and 1,3-butadiene. The diesel particulate matter present in diesel exhaust consists mostly of fine particles (< 2.5 µm), of which a significant fraction is ultrafine particles (< 0.1 µm). These particles have a large surface area which makes them an excellent medium for adsorbing organics, and their small size makes them highly respirable. Many of the organic compounds present in the gases and on the particles, such as polycyclic organic matter, are individually known to have mutagenic and carcinogenic properties.

Diesel exhaust varies significantly in chemical composition and particle sizes between different engine types (heavy-duty, light-duty), engine operating conditions (idle, acceleration, deceleration), and fuel

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

formulations (high/low sulfur fuel). Also, there are emissions differences between on-road and nonroad engines because the nonroad engines are generally of older technology. After being emitted in the engine exhaust, diesel exhaust undergoes dilution as well as chemical and physical changes in the atmosphere. The lifetime for some of the compounds present in diesel exhaust ranges from hours to days.

(b) *Health Effects of Diesel Exhaust*

In EPA's 2002 Diesel Health Assessment Document (Diesel HAD), exposure to diesel exhaust was classified as likely to be carcinogenic to humans by inhalation from environmental exposures, in accordance with the revised draft 1996/1999 EPA cancer guidelines.^{2206,2207} A number of other agencies (National Institute for Occupational Safety and Health, the International Agency for Research on Cancer, the World Health Organization, California EPA, and the U.S. Department of Health and Human Services) had made similar hazard classifications prior to 2002. EPA also concluded in the 2002 Diesel HAD that it was not possible to calculate a cancer unit risk for diesel exhaust due to limitations in the exposure data for the occupational groups or the absence of a dose-response relationship.

In the absence of a cancer unit risk, the Diesel HAD sought to provide additional insight into the significance of the diesel exhaust cancer hazard by estimating possible ranges of risk that might be present in the population. An exploratory analysis was used to characterize a range of possible lung cancer risk. The outcome was that environmental risks of cancer from long-term diesel exhaust exposures could plausibly range from as low as 10^{-5} to as high as 10^{-3} . Because of uncertainties, the analysis acknowledged that the risks could be lower than 10^{-5} , and a zero risk from diesel exhaust exposure could not be ruled out.

Non-cancer health effects of acute and chronic exposure to diesel exhaust emissions are also of concern to EPA. EPA derived a diesel exhaust reference concentration (RfC) from consideration of four well-conducted chronic rat inhalation studies showing adverse pulmonary effects. The RfC is $5 \mu\text{g}/\text{m}^3$ for diesel exhaust measured as diesel particulate matter. This RfC does not consider allergenic effects such as those associated with asthma or immunologic or the potential for cardiac effects. There was emerging evidence in 2002, discussed in the Diesel HAD, that exposure to diesel exhaust can exacerbate these effects, but the exposure-response data were lacking at that time to derive an RfC based on these then-emerging considerations. The EPA Diesel HAD stated, "With [diesel particulate matter] being a ubiquitous component of ambient PM, there is an uncertainty about the adequacy of the existing [diesel exhaust] noncancer database to identify all of the pertinent [diesel exhaust]-caused noncancer health hazards." The Diesel HAD also noted "that acute exposure to [diesel exhaust] has been associated with irritation of the eye, nose, and throat, respiratory symptoms (cough and phlegm), and neurophysiological symptoms such as headache, lightheadedness, nausea, vomiting, and numbness or tingling of the extremities." The Diesel HAD noted that the cancer and noncancer hazard conclusions applied to the general use of diesel engines then on the market and as cleaner engines replace a substantial number of existing ones, the applicability of the conclusions would need to be reevaluated.

It is important to note that the Diesel HAD also briefly summarized health effects associated with ambient PM and discusses EPA's then-annual $\text{PM}_{2.5}$ NAAQS of $15 \mu\text{g}/\text{m}^3$. In 2012, EPA revised the annual

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

PM_{2.5} NAAQS to 12 µg/m³. There is a large and extensive body of human data showing a wide spectrum of adverse health effects associated with exposure to ambient PM, of which diesel exhaust is an important component. The PM_{2.5} NAAQS is designed to provide protection from the noncancer health effects and premature mortality attributed to exposure to PM_{2.5}. The contribution of diesel PM to total ambient PM varies in different regions of the country and also, within a region, from one area to another. The contribution can be high in near-roadway environments, for example, or in other locations where diesel engine use is concentrated.

Since 2002, several new studies have been published which continue to report increased lung cancer risk with occupational exposure to diesel exhaust from older engines. Of particular note since 2011 are three new epidemiology studies which have examined lung cancer in occupational populations, for example, truck drivers, underground nonmetal miners and other diesel motor-related occupations. These studies reported increased risk of lung cancer with exposure to diesel exhaust with evidence of positive exposure-response relationships to varying degrees.^{2208,2209,2210} These newer studies (along with others that have appeared in the scientific literature) add to the evidence EPA evaluated in the 2002 Diesel HAD and further reinforces the concern that diesel exhaust exposure likely poses a lung cancer hazard. The findings from these newer studies do not necessarily apply to newer technology diesel engines because the newer engines have large reductions in the emission constituents compared to older technology diesel engines.

In light of the growing body of scientific literature evaluating the health effects of exposure to diesel exhaust, in June 2012 the World Health Organization's International Agency for Research on Cancer (IARC), a recognized international authority on the carcinogenic potential of chemicals and other agents, evaluated the full range of cancer-related health effects data for diesel engine exhaust. IARC concluded that diesel exhaust should be regarded as "carcinogenic to humans."²²¹¹ This designation was an update from its 1988 evaluation that considered the evidence to be indicative of a "probable human carcinogen."

(c) *Current Concentrations*

Because DPM is part of overall ambient PM and cannot be easily distinguished from overall PM, we do not have direct measurements of DPM in the ambient air. DPM concentrations are estimated using ambient air quality modeling based on DPM emission inventories. DPM emission inventories are computed as the exhaust PM emissions from mobile sources combusting diesel or residual oil fuel. DPM concentrations were recently estimated as part of the 2014 NATA. Areas with high concentrations are clustered in the Northeast, Great Lake States, California, and the Gulf Coast States and are also distributed throughout the rest of the U.S.

(7) *Air Toxics*

(a) *Background*

Light-duty vehicle emissions contribute to ambient levels of air toxics that are known or suspected human or animal carcinogens, or that have noncancer health effects. The population experiences an elevated risk of cancer and other noncancer health effects from exposure to the class of pollutants known collectively as “air toxics.”²²¹² These compounds include, but are not limited to, benzene, 1,3-butadiene, formaldehyde, acetaldehyde, acrolein, polycyclic organic matter, and naphthalene. These compounds were identified as national or regional risk drivers or contributors in the 2014 or past National-scale Air Toxics Assessment and have significant inventory contributions from mobile sources.^{2213,2214}

(b) *Benzene*

EPA’s Integrated Risk Information System (IRIS) database lists benzene as a known human carcinogen (causing leukemia) by all routes of exposure, and concludes that exposure is associated with additional health effects, including genetic changes in both humans and animals and increased proliferation of bone marrow cells in mice.^{2215, 2216, 2217} EPA states in its IRIS database that data indicate a causal relationship between benzene exposure and acute lymphocytic leukemia and suggest a relationship between benzene exposure and chronic non-lymphocytic leukemia and chronic lymphocytic leukemia. EPA’s IRIS documentation for benzene also lists a range of 2.2×10^{-6} to 7.8×10^{-6} per $\mu\text{g}/\text{m}^3$ as the unit risk estimate (URE) for benzene.^{2218, 2219} The International Agency for Research on Cancer (IARC) has determined that benzene is a human carcinogen and the U.S. Department of Health and Human Services (DHHS) has characterized benzene as a known human carcinogen.^{2220,2221}

A number of adverse noncancer health effects including blood disorders, such as pre-leukemia and aplastic anemia, have also been associated with long-term exposure to benzene. The most sensitive noncancer effect observed in humans, based on current data, is the depression of the absolute lymphocyte count in blood. EPA's inhalation reference concentration (RfC) for benzene is 30 µg/m³. The RfC is based on suppressed absolute lymphocyte counts seen in humans under occupational exposure conditions. In addition, recent work, including studies sponsored by the Health Effects Institute, provides evidence that biochemical responses are occurring at lower levels of benzene exposure than previously known.^{2222, 2223, 2224, 2225} EPA's IRIS program has not yet evaluated these new data. EPA does not currently have an acute reference concentration for benzene. The Agency for Toxic Substances and Disease Registry (ATSDR) Minimal Risk Level (MRL) for acute exposure to benzene is 29 µg/m³ for 1-14 days exposure.

(c) *1,3-Butadiene*

EPA has characterized 1,3-butadiene as carcinogenic to humans by inhalation.^{2226, 2227} The IARC has determined that 1,3-butadiene is a human carcinogen and the U.S. DHHS has characterized 1,3-butadiene as a known human carcinogen.^{2228, 2229, 2230, 2231} There are numerous studies consistently demonstrating that 1,3-butadiene is metabolized into genotoxic metabolites by experimental animals and humans. The specific mechanisms of 1,3-butadiene-induced carcinogenesis are unknown; however, the scientific evidence strongly suggests that the carcinogenic effects are mediated by genotoxic metabolites. Animal data suggest that females may be more sensitive than males for cancer effects associated with 1,3-butadiene exposure; there are insufficient data in humans from which to draw conclusions about sensitive subpopulations. The URE

 for 1,3-butadiene is 3×10^{-5} per $\mu\text{g}/\text{m}^3$.²²³² 1,3-butadiene also causes a variety of reproductive and developmental effects in mice; no human data on these effects are available. The most sensitive effect was ovarian atrophy observed in a lifetime bioassay of female mice.²²³³ Based on this critical effect and the benchmark concentration methodology, an RfC for chronic health effects was calculated at 0.9 ppb (approximately $2 \mu\text{g}/\text{m}^3$).

(d) *Formaldehyde*

In 1991, EPA concluded that formaldehyde is a carcinogen based on nasal tumors in animal bioassays.²²³⁴ An Inhalation URE for cancer and a Reference Dose for oral noncancer effects were developed by the agency and posted on the IRIS database. Since that time, the National Toxicology Program (NTP) and International Agency for Research on Cancer (IARC) have concluded that formaldehyde is a known human carcinogen.^{2235,2236,2237}

The conclusions by IARC and NTP reflect the results of epidemiologic research published since 1991 in combination with previous animal, human and mechanistic evidence. Research conducted by the National Cancer Institute reported an increased risk of nasopharyngeal cancer and specific lymph hematopoietic malignancies among workers exposed to formaldehyde.^{2238,2239,2240} A National Institute of Occupational Safety and Health study of garment workers also reported increased risk of death due to leukemia among workers exposed to formaldehyde.²²⁴¹ Extended follow-up of a cohort of British chemical workers did not report evidence of an increase in nasopharyngeal or lymph hematopoietic cancers, but a continuing statistically significant excess in lung cancers was reported.²²⁴² Finally, a study of embalmers reported formaldehyde exposures to be associated with an increased risk of myeloid leukemia but not brain cancer.²²⁴³

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Health effects of formaldehyde in addition to cancer were reviewed by the Agency for Toxic Substances and Disease Registry in 1999,²²⁴⁴ supplemented in 2010,²²⁴⁵ and by the World Health Organization.²²⁴⁶ These organizations reviewed the scientific literature concerning health effects linked to formaldehyde exposure to evaluate hazards and dose response relationships and defined exposure concentrations for minimal risk levels (MRLs). The health endpoints reviewed included sensory irritation of eyes and respiratory tract, reduced pulmonary function, nasal histopathology, and immune system effects. In addition, research on reproductive and developmental effects and neurological effects were discussed along with several studies that suggest that formaldehyde may increase the risk of asthma—particularly in the young.

EPA released a draft Toxicological Review of Formaldehyde – Inhalation Assessment through the IRIS program for peer review by the National Research Council (NRC) and public comment in June 2010.²²⁴⁷ The draft assessment reviewed more recent research from animal and human studies on cancer and other health effects. The NRC released their review report in April 2011.²²⁴⁸ EPA is currently developing a revised draft assessment in response to this review.

(e) *Acetaldehyde*

Acetaldehyde is classified in EPA’s IRIS database as a probable human carcinogen, based on nasal tumors in rats, and is considered toxic by the inhalation, oral, and intravenous routes.²²⁴⁹ The URE in IRIS for acetaldehyde is 2.2×10^{-6} per $\mu\text{g}/\text{m}^3$.²²⁵⁰ Acetaldehyde is reasonably anticipated to be a human carcinogen by the U.S. DHHS in the 13th Report on Carcinogens and is classified as possibly carcinogenic to humans (Group 2B) by the IARC.^{2251,2252} Acetaldehyde is currently listed on the IRIS Program Multi-Year Agenda for reassessment within the next few years.

The primary noncancer effects of exposure to acetaldehyde vapors include irritation of the eyes, skin, and respiratory tract.²²⁵³ In short-term (4 week) rat studies, degeneration of olfactory epithelium was

observed at various concentration levels of acetaldehyde exposure.^{2254,2255} Data from these studies were used by EPA to develop an inhalation reference concentration of $9 \mu\text{g}/\text{m}^3$. Some asthmatics have been shown to be a sensitive subpopulation to decrements in functional expiratory volume (FEV1 test) and bronchoconstriction upon acetaldehyde inhalation.²²⁵⁶

(f) *Acrolein*

EPA most recently evaluated the toxicological and health effects literature related to acrolein in 2003 and concluded that the human carcinogenic potential of acrolein could not be determined because the available data were inadequate. No information was available on the carcinogenic effects of acrolein in humans and the animal data provided inadequate evidence of carcinogenicity.²²⁵⁷ The IARC determined in 1995 that acrolein was not classifiable as to its carcinogenicity in humans.²²⁵⁸

Lesions to the lungs and upper respiratory tract of rats, rabbits, and hamsters have been observed after sub-chronic exposure to acrolein.²²⁵⁹ The agency has developed an RfC for acrolein of $0.02 \mu\text{g}/\text{m}^3$ and an RfD of $0.5 \mu\text{g}/\text{kg}\cdot\text{day}$.²²⁶⁰

Acrolein is extremely acrid and irritating to humans when inhaled, with acute exposure resulting in upper respiratory tract irritation, mucus hypersecretion and congestion. The intense irritancy of this carbonyl has been demonstrated during controlled tests in human subjects, who suffer intolerable eye and nasal mucosal sensory reactions within minutes of exposure.²²⁶¹ These data and additional studies regarding acute effects of human exposure to acrolein are summarized in EPA's 2003 Toxicological Review of Acrolein.²²⁶² Studies in humans indicate that levels as low as 0.09 ppm ($0.21 \text{ mg}/\text{m}^3$) for five minutes may elicit subjective complaints of eye irritation with increasing concentrations leading to more extensive eye, nose and respiratory symptoms. Acute exposures in animal studies report bronchial hyper-responsiveness. Based on animal data (more pronounced respiratory irritancy in mice with allergic airway disease in comparison to

non-diseased mice²²⁶³) and demonstration of similar effects in humans (e.g., reduction in respiratory rate), individuals with compromised respiratory function (e.g., emphysema, asthma) are expected to be at increased risk of developing adverse responses to strong respiratory irritants such as acrolein. EPA does not currently have an acute reference concentration for acrolein. The available health effect reference values for acrolein have been summarized by EPA and include an ATSDR MRL for acute exposure to acrolein of 7 µg/m³ for 1-14 days' exposure; and Reference Exposure Level (REL) values from the California Office of Environmental Health Hazard Assessment (OEHHA) for one-hour and 8-hour exposures of 2.5 µg/m³ and 0.7 µg/m³, respectively.²²⁶⁴

(g) *Polycyclic Organic Matter*

The term polycyclic organic matter (POM) defines a broad class of compounds that includes the polycyclic aromatic hydrocarbon compounds (PAHs). One of these compounds, naphthalene, is discussed separately below. POM compounds are formed primarily from combustion and are present in the atmosphere in gas and particulate form. Cancer is the major concern from exposure to POM. Epidemiologic studies have reported an increase in lung cancer in humans exposed to diesel exhaust, coke oven emissions, roofing tar emissions, and cigarette smoke; all of these mixtures contain POM compounds.^{2265,2266} Animal studies have reported respiratory tract tumors from inhalation exposure to benzo[a]pyrene and alimentary tract and liver tumors from oral exposure to benzo[a]pyrene.²²⁶⁷ In 1997 EPA classified seven PAHs (benzo[a]pyrene, benz[a]anthracene, chrysene, benzo[b]fluoranthene, benzo[k]fluoranthene, dibenz[a,h]anthracene, and indeno[1,2,3-cd]pyrene) as Group B2, probable human carcinogens.²²⁶⁸ Since that time, studies have found that maternal exposures to PAHs in a population of pregnant women were associated with several adverse birth outcomes, including low birth weight and reduced length at birth, as well as impaired cognitive development in preschool children (3 years of age).^{2269,2270} These and similar studies are being evaluated as a part of the ongoing IRIS reassessment of health effects associated with exposure to benzo[a]pyrene.

(h) *Naphthalene*

Naphthalene is found in small quantities in gasoline and diesel fuels. Naphthalene emissions have been measured in larger quantities in both gasoline and diesel exhaust compared with evaporative emissions from mobile sources, indicating it is primarily a product of combustion. Acute (short-term) exposure of humans to naphthalene by inhalation, ingestion, or dermal contact is associated with hemolytic anemia and damage to the liver and the nervous system.²²⁷¹ Chronic (long term) exposure of workers and rodents to naphthalene has been reported to cause cataracts and retinal damage.²²⁷² The National Toxicology Program listed naphthalene as "reasonably anticipated to be a human carcinogen" in 2004 on the basis of bioassays reporting clear evidence of carcinogenicity in rats and some evidence of carcinogenicity in mice.²²⁷³ California EPA has released a new risk assessment for naphthalene, and the IARC has reevaluated naphthalene and re-classified it as Group 2B: possibly carcinogenic to humans.²²⁷⁴

Naphthalene also causes a number of chronic non-cancer effects in animals, including abnormal cell changes and growth in respiratory and nasal tissues.²²⁷⁵ The current EPA IRIS assessment includes noncancer data on hyperplasia and metaplasia in nasal tissue that form the basis of the inhalation RfC of 3 $\mu\text{g}/\text{m}^3$.²²⁷⁶ The ATSDR MRL for acute exposure to naphthalene is 0.6 mg/kg/day.

(i) *Other Air Toxics*

In addition to the compounds described above, other compounds in gaseous hydrocarbon and PM emissions from motor vehicles will be affected by this action. Mobile source air toxic compounds that will potentially be impacted include ethylbenzene, propionaldehyde, toluene, and xylene. Information regarding the health effects of these compounds can be found in EPA's IRIS database.²²⁷⁷

(j) *Current Concentrations*

The most recent available data indicate that the majority of Americans continue to be exposed to ambient concentrations of air toxics at levels which have the potential to cause adverse health effects. The levels of air toxics to which people are exposed vary depending on where people live and work and the kinds of activities in which they engage, as discussed in detail in EPA's most recent Mobile Source Air Toxics Rule. According to the National Air Toxic Assessment (NATA) for 2014, mobile sources were responsible

for 51 percent of outdoor anthropogenic toxic emissions and were the largest contributor to cancer and noncancer risk from directly emitted pollutants. Mobile sources are also significant contributors to precursor emissions which react to form air toxics. Formaldehyde is the largest contributor to cancer risk of all 71 pollutants quantitatively assessed in the 2014 NATA. Mobile sources were responsible for more than 30 percent of primary anthropogenic emissions of this pollutant in 2014 and also contribute to formaldehyde precursor emissions. Benzene is also a large contributor to cancer risk, and mobile sources account for approximately 54 percent of ambient exposure. Over the years, EPA has implemented a number of mobile source and fuel controls which have resulted in VOC reductions, which also reduced formaldehyde, benzene and other air toxic emissions.

(k) *Exposure and Health Effects Associated with Traffic*

Locations in close proximity to major roadways generally have elevated concentrations of many air pollutants emitted from motor vehicles. Hundreds of such studies have been published in peer-reviewed journals, concluding that concentrations of CO, NO, NO₂, benzene, aldehydes, particulate matter, black carbon, and many other compounds are elevated in ambient air within approximately 300-600 meters (approximately 1,000-2,000 feet) of major roadways. Highest concentrations of most pollutants emitted directly by motor vehicles are found at locations within 50 meters (approximately 165 feet) of the edge of a roadway's traffic lanes.

A large-scale review of air quality measurements in the vicinity of major roadways between 1978 and 2008 concluded that the pollutants with the steepest concentration gradients in vicinities of roadways were CO, ultrafine particles, metals, elemental carbon (EC), NO, NO_x, and several VOCs.²²⁷⁸ These pollutants showed a large reduction in concentrations within 100 meters downwind of the roadway. Pollutants that showed more gradual reductions with distance from roadways included benzene, NO₂, PM_{2.5}, and PM₁₀. In the review article, results varied based on the method of statistical analysis used to determine the trend.

For pollutants with relatively high background concentrations relative to near-road concentrations, detecting concentration gradients can be difficult. For example, many aldehydes have high background concentrations as a result of photochemical breakdown of precursors from many different organic compounds. This can make detection of gradients around roadways and other primary emission sources difficult. However, several studies have measured aldehydes in multiple weather conditions and found higher concentrations of many carbonyls downwind of roadways.^{2279,2280} These findings suggest a substantial roadway source of these carbonyls.

In the past 15 years, many studies have been published with results reporting that populations who live, work, or go to school near high-traffic roadways experience higher rates of numerous adverse health

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

effects, compared to populations far away from major roads.²²⁸¹ In addition, numerous studies have found adverse health effects associated with spending time in traffic, such as commuting or walking along high-traffic roadways.^{2282,2283,2284,2285} The health outcomes with the strongest evidence linking them with traffic-associated air pollutants are respiratory effects, particularly in asthmatic children, and cardiovascular effects.

Numerous reviews of this body of health literature have been published as well. In 2010, an expert panel of the Health Effects Institute (HEI) published a review of hundreds of exposure, epidemiology, and toxicology studies.²²⁸⁶ The panel rated how the evidence for each type of health outcome supported a conclusion of a causal association with traffic-associated air pollution as either “sufficient,” “suggestive but not sufficient,” or “inadequate and insufficient.” The panel categorized evidence of a causal association for exacerbation of childhood asthma as “sufficient.” The panel categorized evidence of a causal association for new onset asthma as between “sufficient” and “suggestive but not sufficient.” “Suggestive of a causal association” was how the panel categorized evidence linking traffic-associated air pollutants with exacerbation of adult respiratory symptoms and lung function decrement. It categorized as “inadequate and insufficient” evidence of a causal relationship between traffic-related air pollution and health care utilization for respiratory problems, new onset adult asthma, chronic obstructive pulmonary disease (COPD), nonasthmatic respiratory allergy, and cancer in adults and children. Other literature reviews have been published with conclusions generally similar to the HEI panel’s.^{2287,2288,2289,2290} However, in 2014, researchers from the U.S. Centers for Disease Control and Prevention (CDC) published a systematic review and meta-analysis of studies evaluating the risk of childhood leukemia associated with traffic exposure and reported positive associations between “postnatal” proximity to traffic and leukemia risks, but no such association for “prenatal” exposures.²²⁹¹

Health outcomes with few publications suggest the possibility of other effects still lacking sufficient evidence to draw definitive conclusions. Among these outcomes with a small number of positive studies are

²²⁸¹ In the widely-used PubMed database of health publications, between January 1, 1990 and August 18, 2011, 605 publications contained the keywords “traffic, pollution, epidemiology,” with approximately half the studies published after 2007.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

neurological impacts (e.g., autism and reduced cognitive function) and reproductive outcomes (e.g., preterm birth, low birth weight).^{2292,2293,2294,2295}

In addition to health outcomes, particularly cardiopulmonary effects, conclusions of numerous studies suggest mechanisms by which traffic-related air pollution affects health. Numerous studies indicate that near-roadway exposures may increase systemic inflammation, affecting organ systems, including blood vessels and lungs.^{2296,2297,2298,2299} Long-term exposures in near-road environments have been associated with inflammation-associated conditions, such as atherosclerosis and asthma.^{2300,2301,2302}

Several studies suggest that some factors may increase susceptibility to the effects of traffic-associated air pollution. Several studies have found stronger respiratory associations in children experiencing chronic social stress, such as in violent neighborhoods or in homes with high family stress.^{2303,2304,2305}

The risks associated with residence, workplace, or schools near major roads are of potentially high public health significance due to the large population in such locations. According to the 2009 American Housing Survey, over 22 million homes (17.0 percent of all U.S. housing units) were located within 300 feet of an airport, railroad, or highway with four or more lanes. This corresponds to a population of more than 50 million U.S. residents in close proximity to high-traffic roadways or other transportation sources. Based on

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

2010 Census data, a 2013 publication estimated that 19 percent of the U.S. population (over 59 million people) lived within 500 meters of roads with at least 25,000 annual average daily traffic (AADT), while about 3.2 percent of the population lived within 100 meters (about 300 feet) of such roads.²³⁰⁶ Another 2013 study estimated that 3.7 percent of the U.S. population (about 11.3 million people) lived within 150 meters (about 500 feet) of interstate highways or other freeways and expressways.²³⁰⁷ On average, populations near major roads have higher fractions of minority residents and lower socioeconomic status. Furthermore, on average, Americans spend more than an hour traveling each day, bringing nearly all residents into a high-exposure microenvironment for part of the day.

In light of these concerns, EPA has required through the NAAQS process that air quality monitors be placed near high-traffic roadways for determining concentrations of CO, NO₂, and PM_{2.5} (in addition to those existing monitors located in neighborhoods and other locations farther away from pollution sources). Near-roadway monitors for NO₂ began operation between 2014 and 2017 in Core Based Statistical Areas (CBSAs) with population of at least 500,000. Monitors for CO and PM_{2.5} began operation between 2015 and 2017. These monitors will further the understanding of exposure in these locations.

EPA and DOT continue to research near-road air quality, including the types of pollutants found in high concentrations near major roads and health problems associated with the mixture of pollutants near roads.

(8) *Environmental Effects of Non-GHG Pollutants*

(a) *Visibility*

Visibility can be defined as the degree to which the atmosphere is transparent to visible light.²³⁰⁸ Visibility impairment is caused by light scattering and absorption by suspended particles and gases. Visibility is important because it has direct significance to people's enjoyment of daily activities in all parts of the country. Individuals value good visibility for the well-being it provides them directly, where they live and work, and in places where they enjoy recreational opportunities. Visibility is also highly valued in significant natural areas, such as national parks and wilderness areas, and special emphasis is given to protecting visibility in these areas. For more information on visibility see the final 2019 PM ISA.^{2309,2310}

EPA is working to address visibility impairment. Reductions in air pollution from implementation of various programs associated with the Clean Air Act Amendments of 1990 (CAAA) provisions have resulted in substantial improvements in visibility and will continue to do so in the future. Because trends in haze are closely associated with trends in particulate sulfate and nitrate due to the relationship between their

²³¹⁰ There is an ongoing review of the ISA for Oxides of Nitrogen, Oxides of Sulfur, and Particulate Matter (Ecological Criteria), Available at <https://www.epa.gov/isa/integrated-science-assessment-isa-oxides-nitrogen-oxides-sulfur-and-particulate-matter>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

concentration and light extinction, visibility trends have improved as emissions of SO₂ and NO_x have decreased over time due to air pollution regulations such as the Acid Rain Program.²³¹¹

In the Clean Air Act Amendments of 1977, Congress recognized visibility's value to society by establishing a national goal to protect national parks and wilderness areas from visibility impairment caused by manmade pollution.²³¹² In 1999, EPA finalized the regional haze program to protect the visibility in Mandatory Class I Federal areas.²³¹³ There are 156 national parks, forests and wilderness areas categorized as Mandatory Class I Federal areas.²³¹⁴ These areas are defined in CAA Section 162 as those national parks exceeding 6,000 acres, wilderness areas and memorial parks exceeding 5,000 acres, and all international parks which were in existence on August 7, 1977.

EPA has also concluded that PM_{2.5} causes adverse effects on visibility in other areas that are not targeted by the Regional Haze Rule, such as urban areas, depending on PM_{2.5} concentrations and other factors such as dry chemical composition and relative humidity (i.e., an indicator of the water composition of the particles). EPA revised the PM_{2.5} standards in December 2012 and established a target level of protection that is expected to be met through attainment of the existing secondary standards for PM_{2.5}.

(b) *Plant and Ecosystem Effects of Ozone*

The welfare effects of ozone include effects on ecosystems, which can be observed across a variety of scales, i.e. subcellular, cellular, leaf, whole plant, population and ecosystem. Ozone can produce both acute and chronic injury in sensitive species depending on the concentration level and the duration of the exposure.²³¹⁵ In those sensitive species,²³¹⁶ effects from repeated exposure to ozone throughout the growing season of the plant can tend to accumulate, so that even relatively low concentrations experienced for a longer duration have the potential to create chronic stress on vegetation.²³¹⁷ Ozone damage to sensitive species includes impaired photosynthesis and visible injury to leaves. The impairment of photosynthesis, the process by which the plant makes carbohydrates (its source of energy and food), can lead to reduced crop yields, timber production, and plant productivity and growth. Impaired photosynthesis can also lead to a reduction in root growth and carbohydrate storage below ground, resulting in other, more subtle plant and ecosystems impacts.²³¹⁸ These latter impacts include increased susceptibility of plants to insect attack, disease, harsh weather, interspecies competition and overall decreased plant vigor. The adverse effects of ozone on areas with sensitive species could potentially lead to species shifts and loss from the affected

²³¹³ 64 FR 35714 (July 1, 1999).

²³¹⁴ 62 FR 38680-81 (July 18, 1997).

²³¹⁵ 73 FR 16486 (March 27, 2008).

²³¹⁶ 73 FR 16491 (March 27, 2008). Only a small percentage of all the plant species growing within the U.S. (over 43,000 species have been catalogued in the USDA PLANTS database) have been studied with respect to ozone sensitivity.

²³¹⁷ The concentration at which ozone levels overwhelm a plant's ability to detoxify or compensate for oxidant exposure varies. Thus, whether a plant is classified as sensitive or tolerant depends in part on the exposure levels being considered. Chapter 9, Section 9.3.4 of U.S. EPA, 2013 Integrated Science Assessment for Ozone and Related Photochemical Oxidants. Office of Research and Development/National Center for Environmental Assessment. U.S. Environmental Protection Agency. EPA 600/R-10/076F.

²³¹⁸ 73 FR 16492 (March 27, 2008).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

ecosystems,²³¹⁹ resulting in a loss or reduction in associated ecosystem goods and services. Additionally, visible ozone injury to leaves can result in a loss of aesthetic value in areas of special scenic significance like national parks and wilderness areas and reduced use of sensitive ornamentals in landscaping.²³²⁰

The most recent Integrated Science Assessment (ISA) for Ozone presents more detailed information on how ozone affects vegetation and ecosystems.^{2321,2322} The ISA concludes that ambient concentrations of ozone are associated with a number of adverse welfare effects and characterizes the weight of evidence for different effects associated with ozone.²³²³ The ISA concludes that visible foliar injury effects on some vegetation, reduced vegetation growth, reduced productivity in terrestrial ecosystems, reduced yield and quality of some agricultural crops, and alteration of below-ground biogeochemical cycles are causally associated with exposure to ozone. It also concludes that reduced carbon sequestration in terrestrial ecosystems, alteration of terrestrial ecosystem water cycling, and alteration of terrestrial community composition are likely to be causally associated with exposure to ozone.

(c) *Atmospheric Deposition*

Wet and dry deposition of ambient particulate matter delivers a complex mixture of metals (e.g., mercury, zinc, lead, nickel, aluminum, and cadmium), organic compounds (e.g., polycyclic organic matter, dioxins, and furans) and inorganic compounds (e.g., nitrate, sulfate) to terrestrial and aquatic ecosystems. The chemical form of the compounds deposited depends on a variety of factors including ambient conditions (e.g., temperature, humidity, oxidant levels) and the sources of the material. Chemical and physical transformations of the compounds occur in the atmosphere as well as the media onto which they deposit. These transformations in turn influence the fate, bioavailability and potential toxicity of these compounds.

Adverse impacts to human health and the environment can occur when particulate matter is deposited to soils, water, and biota.²³²⁴ Deposition of heavy metals or other toxics may lead to the human ingestion of contaminated fish, impairment of drinking water, damage to terrestrial, freshwater and marine ecosystem components, and limits to recreational uses. Atmospheric deposition has been identified as a key component of the environmental and human health hazard posed by several pollutants including mercury, dioxin and PCBs.²³²⁵

The ecological effects of acidifying deposition and nutrient enrichment are detailed in the Integrated Science Assessment for Oxides of Nitrogen and Sulfur-Ecological Criteria.^{2326,2327} Atmospheric deposition of nitrogen and sulfur contributes to acidification, altering biogeochemistry and affecting animal and plant life in terrestrial and aquatic ecosystems across the United States. The sensitivity of terrestrial and aquatic ecosystems to acidification from nitrogen and sulfur deposition is predominantly governed by geology. Prolonged exposure to excess nitrogen and sulfur deposition in sensitive areas acidifies lakes, rivers and soils. Increased acidity in surface waters creates inhospitable conditions for biota and affects the abundance and biodiversity of fishes, zooplankton and macroinvertebrates and ecosystem function. Over time, acidifying deposition also removes essential nutrients from forest soils, depleting the capacity of soils to neutralize future acid loadings and negatively affecting forest sustainability. Major effects in forests include a decline in sensitive tree species, such as red spruce (*Picea rubens*) and sugar maple (*Acer saccharum*). In addition to the role nitrogen deposition plays in acidification, nitrogen deposition also leads to nutrient enrichment and altered biogeochemical cycling. In aquatic systems increased nitrogen can alter species assemblages and cause eutrophication. In terrestrial systems nitrogen loading can lead to loss of nitrogen-sensitive lichen species, decreased biodiversity of grasslands, meadows and other sensitive habitats, and increased potential for invasive species.

Building materials including metals, stones, cements, and paints undergo natural weathering processes from exposure to environmental elements (e.g., wind, moisture, temperature fluctuations, sunlight, etc.). Pollution can worsen and accelerate these effects. Deposition of PM is associated with both physical damage (materials damage effects) and impaired aesthetic qualities (soiling effects). Wet and dry deposition of PM can physically affect materials, adding to the effects of natural weathering processes, by potentially promoting or accelerating the corrosion of metals, by degrading paints and by deteriorating building materials such as stone, concrete and marble.²³²⁸ The effects of PM are exacerbated by the presence of acidic gases and can be additive or synergistic due to the complex mixture of pollutants in the air and surface characteristics of the material. Acidic deposition has been shown to have an effect on materials including zinc/galvanized steel and other metal, carbonate stone (as monuments and building facings), and surface coatings (paints).²³²⁹ The effects on historic buildings and outdoor works of art are of particular concern because of the uniqueness and irreplaceability of many of these objects. In addition to aesthetic and functional effects on metals, stone and glass, altered energy efficiency of photovoltaic panels by PM deposition is also becoming an important consideration for impacts of air pollutants on materials.

(d) *Environmental Effects of Air Toxics*

Emissions from producing, transporting and combusting fuel contribute to ambient levels of pollutants that contribute to adverse effects on vegetation. Volatile organic compounds, some of which are considered air toxics, have long been suspected to play a role in vegetation damage.²³³⁰ In laboratory

experiments, a wide range of tolerance to VOCs has been observed.²³³¹ Decreases in harvested seed pod weight have been reported for the more sensitive plants, and some studies have reported effects on seed germination, flowering and fruit ripening. Effects of individual VOCs or their role in conjunction with other stressors (e.g., acidification, drought, temperature extremes) have not been well studied. In a recent study of a mixture of VOCs including ethanol and toluene on herbaceous plants, significant effects on seed production, leaf water content and photosynthetic efficiency were reported for some plant species.²³³²

Research suggests an adverse impact of vehicle exhaust on plants, which has in some cases been attributed to aromatic compounds and in other cases to nitrogen oxides.^{2333,2334, 2335} The impacts of VOCs on plant reproduction may have long-term implications for biodiversity and survival of native species near major roadways. Most of the studies of the impacts of VOCs on vegetation have focused on short-term exposure and few studies have focused on long-term effects of VOCs on vegetation and the potential for metabolites of these compounds to affect herbivores or insects.

c) *How the Agencies Estimated Impacts on Emissions*

The rule implements an emissions inventory methodology for estimating impacts. Vehicle emissions inventories are often described as three-legged stools, comprised of activity (i.e., miles traveled, hours operated, or gallons of gasoline burned), population (or number of vehicles), and emission factors. An emissions factor is a representative value that attempts to relate the quantity of a pollutant released to the atmosphere with an activity associated with the release of that pollutant.²³³⁶ Depending on the vehicle activity available, emission factors may be on a distance-, time-, or fuel-basis. For example, an emissions inventory for a light-duty fleet could simply be the vehicle miles traveled multiplied by the appropriate per-mile emission factor for a chosen pollutant.

As described in Chapter VI, Section A, Overview of Methods, the agencies used specific models to develop inputs to the CAFE model, such as fuel prices and emission factors. The CAFE model estimates how manufacturers might respond to a given regulatory scenario (CAFE/ CO₂ standards) and fuel prices, and what impact that response will have on emissions. As mentioned above, the agencies have used DOT's CAFE model to estimate impacts of the CAFE and CO₂ standards promulgated today. Details of the analysis are presented below and in the accompanying RIA, EIS, and model documentation. To estimate the response on emissions, several steps are involved. The estimation of emissions involves accounting for vehicular fuel type (e.g., gasoline, diesel, electric) and fuel economy (accounting for the estimated gap, discussed below, between "laboratory" and actual on-road fuel economy), vehicular turnover and travel demand, fuel properties (carbon content), and upstream process emissions. Like other models, the CAFE model includes procedures to estimate annual rates at which new vehicles are used and subsequently scrapped. Together,

these procedures result in, for each vehicle model in each model year, estimates of the number remaining in service in each calendar year, as well as the annual mileage accumulation (i.e. VMT) in each calendar year. Quantities of emissions derive from this vehicle operation.

For every vehicle model in the market file, the model estimates the VMT per vehicle (using the assumed VMT schedule, the vehicle fuel economy, fuel price, and the rebound assumption). Those miles are multiplied by the number off each vehicle model/configuration remaining in service in any given calendar year. Fuel consumption is the product of miles driven and fuel economy, which can be tracked by model year cohort in the model. Carbon dioxide emissions from vehicle tailpipes are the simple product of gallons consumed and the carbon content of each gallon. As discussed in the CAFE model overview, the simulated application of technology results in estimates of the cost, fuel type, fuel economy, and fuel share applicable to each vehicle model in each model year. Together with quantities of travel, and with estimates of the “gap” between “laboratory” and “on-road” fuel economy, these enable calculation of quantities of fuel consumed in each year during the useful life of each vehicle model produced in each model year. The model calculates emissions of CO₂, CH₄, and N₂O, criteria pollutants, and air toxics, reporting emissions both from vehicle tailpipes and from upstream processes (e.g., petroleum refining) involving in producing and supplying fuels.

In order to calculate calendar year fuel consumption, the model needs to account for the inherited on-road fleet in addition to the model year cohorts affected by this rule. Using the VMT of the average passenger car and light truck from each cohort, the model computes the fuel consumption of each model year class of vehicles for its age in a given CY. The sum across all ages (and thus, model year cohorts) in a given CY provides estimated CY fuel consumption.

For this rule, vehicle tailpipe (downstream) and upstream emission inventories were developed separately. In addition to the tailpipe emissions of carbon dioxide, each gallon of gasoline produced for consumption by the on-road fleet has associated “upstream” emissions that occur in the extraction, transportation, refining, and distribution of the fuel. The tailpipe inventories apply per-mile emission factors from the Motor Vehicle Emission Simulator (MOVES) and the upstream inventories apply per-gallon of fuel consumed emission factors from the Argonne National Laboratory’s Greenhouse gases, Regulated Emissions, and Energy use in Transportation (GREET) Model. The model accounts for upstream emissions and reports them accordingly. More detailed descriptions of emission data sources and calculations are provided in the following section.

The agencies received several comments on estimation of criteria pollutant impacts in the NPRM. As discussed elsewhere in this preamble, EDF modified aspects of the CAFE model as part of their comments to the agencies. Specifically in regards to criteria pollutant emissions, EDF made several alternative assumptions, including assertions that criteria pollutant impacts were not as negligible as the agencies claimed, and that fatalities due to criteria pollutant emissions would be higher than the agencies showed in the NPRM. The agencies declined to adopt EDF’s suggested changes to the model and inputs, but did make the changes discussed in this section that refined the agencies’ accounting of criteria pollutant emissions and explicitly modeled criteria pollutant fatalities, as discussed below.

Also discussed elsewhere in this preamble, some commenters expressed that the agencies’ analysis (by implication, their modeling) should account for some States’ mandates that manufacturers sell minimum

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

quantities of “Zero Emission Vehicles” (ZEVs).²³³⁷ These commenters stressed the importance of the ZEV mandate in relation to maintaining air quality requirements and reducing effects of climate change.

The reference case analysis for today’s rule, like that for the proposal, does not simulate compliance with ZEV mandates,²³³⁸ because such mandates are subject to preemption under EPCA and are therefore not enforceable. As discussed in the [One National Program I – Preemption final rule], California and other states remain free to revise their overall average emissions standards to further reduce ozone forming emissions and seek a waiver of Clean Air Act preemption from EPA, as described above, while not violating NHTSA’s preemption authority. These States and local governments would continue to be allowed to take other actions so long as those are not related to fuel economy and are consistent with any other relevant Federal law.

(1) *Activity levels*

As discussed in Section VI.A, for each vehicle model/configuration in each model year during 2017-2050, the CAFE model estimates and records the fuel type (e.g., gasoline, electricity), fuel economy, and number of units sold in the U.S. The model also makes use of an aggregated representation of vehicles sold in the U.S. during 1978-2016. The model estimates the numbers of each cohort of vehicles remaining in service in each calendar year, and the amount of driving accumulated by each such cohort in each calendar year. The CAFE model estimates annual vehicle-miles of travel (VMT) for each individual car and light truck model produced in each model year at each age of their lifetimes, which extend for a maximum of 40 years. Since a vehicle’s age is equal to the current calendar year minus the model year in which it was originally produced, the age span of each vehicle model’s lifetime corresponds to a sequence of 40 calendar years beginning in the calendar year corresponding to the model year it was produced.²³³⁹ These estimates reflect the gradual decline in the fraction of each car and light truck model’s original model year production volume that is expected to remain in service during each year of its lifetime, as well as the well-documented decline in their typical use as they age. Using this relationship, the CAFE model calculates total VMT for the entire fleet of cars and light trucks in service during each calendar year spanned by the agencies’ analysis.

Based on these estimates, the model also calculates quantities of each type of fuel or energy, including gasoline, diesel, and electricity, consumed in each calendar year. By combining these with estimates of each model’s fuel or energy efficiency, the model also estimates the quantity and energy content of each type of fuel consumed by cars and light trucks at each age, or viewed another way, during each calendar year of their lifetimes. As with the accounting of VMT, these estimates of annual fuel or energy consumption for each vehicle model and model year combination are combined to calculate the total volume of each type of fuel or energy consumed during each calendar year, as well as its aggregate energy content.

²³³⁷ CBD et al., NHTSA-2018-0067-12123; States and Cities, NHTSA-2018-0067-11735; SCAQMD, NHTSA-2018-0067-11813.

²³³⁸ The NPRM version of the model included experimental capabilities to account for mandates and credits for the sale of ZEVs, but the agencies did not utilize those capabilities for the NPRM for the same reasons discussed above.

²³³⁹ In practice, many vehicle models bearing a given model year designation become available for sale in the preceding calendar year, and their sales can extend through the following calendar year as well. However, the CAFE model does not attempt to distinguish between model years and calendar years; vehicles bearing a model year designation are assumed to be produced and sold in that same calendar year.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The procedures the CAFE model uses to estimate annual VMT for individual car and light truck models produced during each model year over their lifetimes and to combine these into estimates of annual fleet-wide travel during each future calendar year, together with the sources of its estimates of their survival rates and average use at each age, are described in detail in Section VI.A of this final rule. The data and procedures it employs to convert these estimates of VMT to fuel and energy consumption by individual model, and to aggregate the results to calculate total consumption and energy content of each fuel type during future calendar years, are also described in detail in that same section.

The model documentation accompanying today's notice describes these procedures in detail.²³⁴⁰ The quantities of travel and fuel consumption estimated for the cross section of model years and calendar years constitutes a set of "activity levels" based on which the model calculates emissions. The model does so by multiplying activity levels by emission factors. As indicated in the previous section, the resulting estimates of vehicle use (VMT), fuel consumption, and fuel energy content are combined with emission factors drawn from various sources to estimate emissions of GHGs, criteria air pollutant, and airborne toxic compound that occur throughout the fuel supply and distribution process, as well as during vehicle operation, storage, and refueling. Emission factors measure the mass of each GHG or criteria pollutant emitted per vehicle-mile of travel, gallon of fuel consumed, or unit of fuel energy content. The following section identifies the sources of these emission factors and explains in detail how the CAFE model applies them to its estimates of vehicle travel, fuel use, and fuel energy consumption to estimate total annual emissions of each GHG, criteria pollutant, and airborne toxic.

(2) *What emission factors did the agencies apply?*

(a) *Tailpipe (Downstream) Emission Factors*

In a full fuel cycle analysis, emissions that occur from the fueling pump to vehicle wheels are usually referred to as tailpipe or simply downstream emissions. Today's rule primarily impacts CO₂ emissions. The agencies have calculated tailpipe CO₂ emissions based on fuel consumption and fuel properties (i.e., fuel density and carbon content) that result in gram per gallon emission factors. For all other exhaust constituents (except sulfur dioxide, discussed below), the agencies have calculated emissions by applying per-mile emission factors to quantities of travel (i.e., VMT). This rulemaking's tailpipe emission factors are from EPA's Motor Vehicle Emission Simulator (MOVES), which serves as the federal regulatory model for mobile-source emission inventories, with a few notable exceptions. In particular, light-duty gasoline and diesel tailpipe emission factors for the following criteria pollutants, greenhouse gases (other than CO₂), and air toxics are drawn from MOVES2014a:²³⁴¹

- Criteria pollutants
 - Carbon monoxide (CO),
 - Volatile organic compounds (VOC),
 - Nitrogen oxides (NO_x), and
 - Fine particulate matter (PM_{2.5})
- Greenhouse gases

²³⁴⁰ CAFE model documentation is available at <https://www.nhtsa.gov/corporate-average-fuel-economy/compliance-and-effects-modeling-system>.

²³⁴¹ For the emission factors informing the Final EIS, updating to MOVES 2014b would have produced values identical to those based on MOVES 2014a.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- Methane (CH₄), and
- Nitrous oxide (N₂O)
- Air toxics
 - Acetaldehyde,
 - Acrolein,
 - Benzene,
 - Butadiene,
 - Formaldehyde,
 - Diesel particulate matter (DPM10), and
 - Methyl tert-butyl ether (MTBE)

These MOVES-based emission factors are specified separately for gasoline and diesel vehicles, by model year (ranging from MY 1975 to 2050), and by vehicle age (ranging from zero to 39 years old). The structure of criteria pollutant emission standards is such that these factors do not vary with fuel economy unless a change in fuel type (e.g., from gasoline to electricity) is involved.

Since tailpipe sulfur dioxide (SO₂) emissions are dependent on the sulfur content of the fuel, a single SO₂ emission factor in grams per million British thermal units (MMBTU) of fuel consumed is applied respectively for gasoline, diesel, and ethanol (E85) across all model years after MY 2017 based on a longitudinal analysis in MOVES.

As previously mentioned, EDF submitted supplemental comments on SO₂ emissions, stating that “SO₂ emissions should be proportional to fuel consumption” and “that the tailpipe SO₂ emissions by calendar year from the Volpe Model do not change proportionally to the changes in fuel consumption across various CO₂ control scenarios.”²³⁴² The version of the model supporting the 2012 final rule calculated tailpipe SO₂ emissions on a gram per gallon basis. Supporting the ensuing rulemaking regarding heavy-duty pickups and vans, and the 2016 draft TAR, EPA staff provided SO₂ emission factors specified on a gram per mile basis. DOT modified the model in order to apply these SO₂ emission factors as provided by EPA. The CAFE Model documentation released with the NPRM clearly describes how the agencies calculated emissions in the model. Although the version of model applied for the NPRM did not change this approach to calculating tailpipe SO₂ emissions, the agencies agree that SO₂ emissions should be proportional to fuel consumption, and DOT has revised the model accordingly. For SO₂ emissions, the inputs to the model include the number of grams of SO₂ emitted by a vehicle per gallon of fuel consumed by the vehicle.

The agencies also received comments on the use of MOVES. Most notably, the National Farmers Union stated “Concerns have been raised regarding the models used by EPA to determine emissions from fuels. Third-party reviews have shown that MOVES2014 may be inadequate as a tool for estimating the exhaust emissions of gasoline blends containing more than 10 percent ethanol. The model’s results for mid-level ethanol blends have been shown to be inconsistent with other results from the scientific literature for both exhaust emissions and evaporative emissions, including results from real-world emissions testing.”²³⁴³ The agencies considered comments on the use of MOVES and ethanol blends and notes that MOVES may be unreliable for fuel blends over E10; however, MOVES is not designed to model mid-level ethanol blends. MOVES2014 is designed to model ethanol volumes up to 15 percent (E0 to E15), and it can also model E85

²³⁴² EDF, NHTSA-2018-0067-12363.

²³⁴³ National Farmers Union, NHTSA-2018-0067-11972.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(ethanol volumes of 70 to 85 percent), but MOVES2014 is not designed to model intermediate fuel blends. Moreover, the agencies did not explicitly consider blends above E10 as part of the analysis, but rather ethanol blending is considered in relation to how to achieve a higher octane level and a higher anti-knock index.

The Pennsylvania Department of Environmental Protection stated that there may be a significant State-specific rebound effect in Pennsylvania given Pennsylvania's regional role in natural gas and petroleum processing and refining. According to this commenter, the proposed rule does not adequately take into account significant local, State, and regional air quality impacts because it dilutes the emissions impact of the rule across the entire Nation. The Center for Biological Diversity, the Consumer Federation of America, and other commenters expressed concern that the proposed rule would increase criteria pollutants in areas with large minority populations, especially those in areas near oil refineries.

Results of these tailpipe emissions calculations are summarized below in Section VII and in the FRIA accompanying today's notice, and presented in greater detail in the accompanying Final EIS.

(b) Upstream Emission Factors

Fuel cycle emissions occurring between the extraction well and the fueling pump are often called upstream emissions. This rule has drawn upstream emission factors exclusively from the Greenhouse gases, Regulated Emissions, and Energy use in Transportation (GREET) model, developed by the U.S. Department of Energy's Argonne National Laboratory. The upstream gasoline, diesel, and electricity emission factors for criteria pollutants—namely, CO, VOC, NO_x, PM_{2.5}, and SO₂—and greenhouse gases—namely, CO₂, CH₄, and N₂O—have been updated with GREET 2018 data. The upstream emission factors for the air toxics mentioned above were unchanged from the proposal. For the final rule, upstream emission factors cover the following analysis years, 2017, 2020, 2025, 2030, 2035, 2040, 2045, and 2050, and four distinct upstream processes:

- Petroleum Extraction,
- Petroleum Transportation,
- Petroleum Refining, and
- Fuel Transportation, Storage, and Distribution (TS&D).

These upstream emission factors for each fuel type and analysis year were generated by a process using emission factor values found in the GREET 2018 spreadsheet tool and adjustment factors where appropriate. Emission factors for the petroleum extraction process are the aggregation of different crude feedstock—such as crude oil, oil sands, and shale oil—emission factors multiplied by their associated adjustments for transportation to refineries losses, storage losses, and energy share by crude feedstock. Emission factors for the petroleum transportation process are emissions by crude feedstock sources—such as crude oil fields, surface and in-situ mining, and shale reserves—and multiplied the associated energy shares. Emission factors for the petroleum refining are the sum of the crude input, combustion, and non-combustion products multiplied by the transportation of blended fuel loss factors. The refining emission factors applies a non-ethanol energy content adjustment for gasoline, blended at E10. Diesel does not have any such ethanol content adjustment. Emission factors for the Fuel TS&D process are based on the blended fuel transportation and distribution emissions as well as an energy content factor for both the petroleum and ethanol portions of the fuels. Again, diesel does not have an ethanol adjustment.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The aggregated upstream emission factors used in the rule are aggregated across the four processes for each fuel type and analysis year. The aggregated upstream emission factor is the sum of the fuel TS&D emission factor, the petroleum refining emission factor multiplied by the share of fuel savings leading to reduced domestic refining, the pair of petroleum extraction and transportation emission factors multiplied by both the share of fuel savings and the share of reduced domestic refining from domestic crude. The upstream adjustments are replicated from the proposal.

Finally, the upstream emission factors for electricity are also updated with GREET 2018 data. Upstream electricity emissions factors are derived from electricity for transportation use feedstock and fuel emissions by analysis year. As the analysis supporting the proposal noted, there are three possible supply “pathways” for fuel consumed by the U.S. light-duty vehicle fleet:

1. Importing fuel that has been refined overseas into the U.S.
2. Refining fuel in the U.S. from crude petroleum produced overseas and imported into the U.S.
3. Refining fuel in the U.S. from crude petroleum produced in the U.S.²³⁴⁴

The distribution of fuel consumed within the U.S. that is supplied via each of these pathways has important implications for domestic “upstream” emissions, because each pathway produces domestic emissions arising from a different combination of activities that occur within the U.S. For example, pathway 1 involves domestic emissions that occur during crude petroleum extraction, transportation of crude oil from production or nearby temporary storage facilities to domestic refineries, refining of crude petroleum to produce transportation fuels, and storage and distribution of refined fuels.²³⁴⁵ In contrast, pathway 2 generates domestic emissions during transportation of crude petroleum from U.S. coastal ports to domestic refineries, as well as from fuel refining, storage, and distribution, while pathway 3 produces domestic emissions only from storage and distribution of refined fuel.

The analysis supporting the proposal made two central assumptions in estimating upstream emissions from fuel supply. First, 50 percent of any change in domestic fuel consumption by cars and light trucks operating on petroleum-based liquid fuels (gasoline and diesel) would be reflected in changes in imports of refined fuel, while the remaining 50 percent would be reflected in changes in the volume of those fuels refined domestically. Second, 90 percent of any change in the volume of fuel refined domestically was assumed to be reflected in changes in the volume of crude petroleum imported into the U.S., with the remaining 10 percent reflected in changes in the volume of crude petroleum produced within the U.S. The agencies developed these assumptions to analyze the environmental impacts of alternative CAFE and CO₂ standards for model years 2012-2016, and have continued to rely in their analyses supporting subsequent rules.

To illustrate the effect of these assumptions, for each increase in domestic fuel consumption of 100 gallons, 50 additional gallons would be supplied via pathway 1 (refined outside the U.S. and imported in already-refined form). Additional fuel supplied via pathway 2 (U.S. domestic refining of imported crude oil) would account for 90 percent of the remaining 50 gallons of increased consumption, or 45 gallons. Finally,

²³⁴⁴ The proposal assumed that all fuel refined outside the U.S. and then imported into the U.S. would be refined from petroleum that was also produced outside the U.S. Although some of it could be refined from crude petroleum produced in the U.S. and exported, the analysis assumed that the fraction supplied via this pathway is negligible.

²³⁴⁵ By longstanding EPA convention, emissions that occur when vehicles are being refueled at retail stations or vehicle storage depots (such as buses) are ascribed to vehicle use, rather than to fuel supply.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

the remaining 5 gallons of increased fuel consumed within the U.S. would be supplied via pathway 3 (domestic refining of crude oil produced within the U.S.). This same breakdown was applied to changes in fuel consumption estimated to occur throughout the analysis period used for the proposal, which extended from 2017 through 2050.

The agencies estimated the resulting changes in upstream emissions of criteria air pollutants and airborne toxics occurring within the U.S. by applying emission factors for the appropriate stages of the fuel supply chain (petroleum extraction, petroleum transportation to refineries, fuel refining, and fuel storage and distribution) to the changes in the total energy content of fuel supplied by each pathway, and summed the results.²³⁴⁶ The energy content of fuel rather than its volume was used as the basis for estimating emissions, because emission factors are typically expressed in mass per unit of fuel energy supplied—for example, grams per million Btu—rather than per unit volume of fuel supplied.

In the proposal, the agencies made no explicit assumptions about the future mix of electric generating capacity that would be used to supply increased electricity consumed by BEVs and PHEVs. Instead, the agencies implicitly relied on the assumptions about future evolution of the nationwide mix of generation sources that were reflected in the U.S. average emission factors for electricity produced to power transportation vehicles, including cars and light trucks, which as described previously were drawn from the most recent version of Argonne National Laboratory's GREET model that was available at the time of the proposal. These assumptions were consistent with those made by EIA in its AEO 2017 Reference case analysis and publications.²³⁴⁷

While the agencies' use of these assumptions to estimate upstream emissions did not prompt widespread comments on their analyses in support of previous CAFE rulemakings, the more recent proposal did draw a large number of comments focusing on those same assumptions. Most commenters asserted that the entirety of any increase in consumption of petroleum-based fuels by cars and light trucks resulting from the proposal would be met via increased domestic refining, primarily from crude petroleum produced in the U.S., and would thus generate additional upstream emissions within the U.S. throughout the fuel supply process. Even some commenters who argued elsewhere that the U.S. would continue to be a large-scale importer of petroleum asserted that the entire increase in fuel consumption resulting from the proposal would be refined from additional domestically-produced petroleum.²³⁴⁸

As a consequence, most commenters argued that the agencies' analysis of the proposal significantly underestimated the increases in upstream emissions that were likely to result, with some also asserting that the increases in emissions of criteria air pollutants would cause potentially serious degradation of air quality in the areas surrounding U.S. refineries. For example, EDF stated, "NHTSA assumed that 50% of all the gasoline saved by more stringent CAFE and CO₂ standards would have been imported (i.e., refined overseas).... It is difficult to see how this could be the case when the nation is producing enough crude oil to

²³⁴⁶ Increases in upstream GHG emissions were calculated from the increase in U.S. domestic fuel consumption, without regard to whether they occurred within the U.S.

²³⁴⁷ <https://greet.es.anl.gov/publication-greet-2017-summary>.

²³⁴⁸ For example, IPI notes that AEO 2019 shows the U.S. will continue to import crude petroleum through 2050, and will remain a net importer as measured by the energy content rather than the volume of U.S. petroleum exports and imports; see IPI, NHTSA-2018-0067-12213. Similarly, EDF argued that because U.S. petroleum imports have been declining and gasoline imports are currently low, the best assumption was that the entire increase in gasoline consumption resulting from the proposal would be supplied from increased domestic refining of U.S.-produced crude petroleum; see EDF, NHTSA-2018-0067-12108.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

be a net exporter. It is also difficult to see how this could be the case when gasoline consumption is decreasing and sufficient domestic refining capacity exists to fulfill today's demand, let alone decreased demand in the future.... Assuming that 100% of the differences in gasoline consumption between control scenarios will be refined in the U.S. appears to be much more consistent with the available data. Likewise, it seems reasonable to assume that differences in the crude oil requirements of the various scenarios will also affect domestic production more so than imports.²³⁴⁹

However, one commenter did agree with the agencies' assessment of the proposal's likely impact on U.S. petroleum imports, noting that "Through 2050, there will only be a small increase in domestic oil production due to increased demand, well under 1%.... The vast majority (88% through 2050) of the additional petroleum that will be required to fuel light-duty vehicles in the proposed case will be imported. This assessment is not too far off of a single comment in the NPRM, 'Using NEMS, it was estimated that 50% of increased gasoline consumption would be supplied by increased domestic refining and that 90% of this additional refining would use imported crude petroleum.'²³⁵⁰

The agencies note that there seems to be considerable confusion among commenters about the agencies' assumptions regarding import shares, and what they are attempting to measure. The agencies' assumptions are intended to measure the effects of *changes* in consumption of petroleum-derived transportation fuels by cars and light trucks that are attributable to this final rule on *changes* in U.S. production and imports of crude petroleum, in domestic refining of crude petroleum to produce transportation fuels, and in the volume of refined fuel distributed for domestic consumption. While recent data on U.S. fuel consumption, domestic production and imports of crude petroleum, and imports of refined petroleum products may be useful in estimating these desired measures, they are not themselves measures of the marginal impacts of changes in fuel consumption on the volumes of fuel supplied via each of the supply pathways described previously.

Instead, the agencies rely on two types of information to estimate the current and likely future values of the desired measures. First, they examine recent changes in domestic consumption of petroleum-based motor fuels—particularly gasoline, since it is the primary fuel used by vehicles that are subject to CAFE and CO₂ standards—and compare them to the accompanying changes in the three gasoline supply pathways, namely domestic petroleum production, U.S. imports of crude petroleum, and U.S. imports of refined gasoline (or components that are blended domestically to produce gasoline). Second, the agencies examine differences in forecasts of U.S. petroleum production, fuel refining, and imports of refined fuel under alternative future scenarios that were included in AEO 2018 whose projections of domestic fuel consumption differ in ways that include alternative CAFE standards. While this latter approach would ideally compare scenarios that differ only in their assumptions about the stringency of CAFE and CO₂ standards but are otherwise strictly comparable, such idealized comparisons are rarely possible because other factors almost always differ as well between the alternative scenarios being compared.

(i) Assumptions Used to Analyze Impacts of the Final Rule on Petroleum Imports and Emissions

In response to comments, the agencies conducted a detailed examination of recent changes in U.S. fuel consumption, domestic fuel refining, and U.S. imports and exports of crude petroleum as well as refined

²³⁴⁹ EDF, NHTSA-2018-0067-12108, p. 53. Others making similar assertions include IPI, NHTSA-2018-0067-12213, p. 5.

²³⁵⁰ David Gohlke, EPA-HQ-OAR-2018-0283-5082, p. 1.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

fuel (primarily gasoline). This included comparing changes in these variables at both the national aggregate level and for three separate regions of the U.S. In addition, they examined differences in the forecast values of these variables under alternative assumptions about fuel economy standards, although as indicated above these comparisons are complicated by the fact that factors other than CAFE and CO₂ standards also differ between these alternative scenarios.

The agencies also identified a fourth “pathway” to supply the increase in U.S. gasoline consumption anticipated to result from this final rule. The U.S. is now a net exporter of refined gasoline (and products that are blended to produce gasoline), and the volume of U.S. gasoline exports is likely to increase for at least the next two decades. This introduces the possibility that some—and perhaps all—of the anticipated increase in domestic gasoline consumption will be met simply by redirecting U.S. gasoline exports to serve domestic consumption. This additional source of supply would result in no increase in domestic refining activity, and thus no increase in emissions from refining of petroleum-based transportation fuels.²³⁵¹

Throughout most of the past half-century, the nation has been a large net importer of crude petroleum, taking its price as determined in world markets and importing the volumes necessary to meet the difference between U.S. demand for refined petroleum products and domestic supplies. Throughout this period, the U.S. has also been largely self-sufficient in refining, meaning that the gap between domestic demand for refined products and the volumes refined from crude petroleum extracted within the U.S. was primarily met by domestic refining of imported crude petroleum, with only marginal volumes of gasoline and other products imported or exported. U.S. refinery capacity and output generally increased over this period in proportion to growth in domestic consumption of fuel and other products refined from petroleum.

In the past decade, however, this situation has changed dramatically. U.S. production of crude petroleum has more than doubled since 2008, making the nation one of the world’s largest producers, while net imports of crude oil and refined products have declined by nearly 80 percent.²³⁵² Domestic gasoline consumption declined by more than 6 percent between 2007 and 2012, and recovered to its 2007 levels only as recently as 2016, remaining near or slightly below its 2016 level since then.²³⁵³ As a consequence, the U.S. shifted from being a net importer of refined petroleum products to a net exporter in 2011, and has become a net exporter of gasoline and “blending stock” since 2016.²³⁵⁴

²³⁵¹ Increased domestic emissions would only occur in this case to the extent that domestic distribution of gasoline entailed higher emissions than transporting it to U.S. coastal ports for export.

²³⁵² These and other petroleum statistics cited here were calculated from data available at EIA, Petroleum and Other Liquids, 2019, <https://www.eia.gov/petroleum/data.php>. U.S. production of crude petroleum rose from 1.83 billion barrels in 2008 to 4.01 billion barrels in 2018, or by 119%. During that same period, net U.S. imports of crude petroleum and refined products declined from 4.07 billion to 0.85 billion barrels, or by 79%. Net U.S. imports are the difference between the nation’s total (or gross) imports from elsewhere in the world and the volumes it exports to other nations.

²³⁵³ U.S. gasoline consumption declined from 3.39 billion barrels in 2007 to 3.18 billion barrels in 2012, or by 6.2 percent, rose to 3.41 billion barrels in 2016, and remained near that level through 2018.

²³⁵⁴ In 2010, U.S. net imports of refined petroleum products were 98 million barrels, but by 2011 U.S. net exports were 160 million barrels. U.S. net exports of refined products then increased steadily through 2018, reaching 1.23 billion barrels in that year. In 2015, U.S. net imports of gasoline and blending components totaled 19 million barrels, but by 2016, U.S. net exports were 20 million barrels, and grew to 93 million barrels in 2018. Another recent change in petroleum markets has been the increasing production and trade in gasoline blendstock in domestic and international petroleum trade. While in earlier periods refineries normally produced finished gasoline and shipped it to local storage terminals for distribution and retailing, in recent years, refineries have increasingly shifted to producing standardized gasoline blendstocks, such as Reformulated Blendstock for Oxygenate Blending (or “RBOB”), which are then shipped and blended with ethanol or other additives to make finished gasoline

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Over the past decade, increased availability of crude petroleum and other refinery feedstocks in combination with declining gasoline consumption has presented U.S. refiners with a choice between continuing to produce gasoline at or near their capacity while boosting exports, or cutting back on refinery output. U.S. refiners elected not to cut back on their production of gasoline; instead, they actually increased the volume they refined. U.S. production of finished gasoline increased by 9 percent between 2007 and 2018.

The excess of gasoline production resulting from increased refinery capacity and stable consumption has partly displaced previous gasoline and blendstock imports, with the remainder taking the form of increased U.S. exports. Thus, as Figure VI-1 below shows, the nation now has a capacity to produce gasoline that considerably exceeds its current domestic consumption. This surplus of gasoline appears likely to increase in coming few years, as EIA's *Annual Energy Outlook 2019* reference case (EIA, 2019) anticipates that domestic gasoline consumption will continue to decline until nearly 2040. Therefore, the U.S. seems likely to remain a net exporter of gasoline through the next three decades.

that meets local regulatory requirements or customer specifications. Although this process has clear cost and operational advantages, particularly with extensive geographic and seasonal variation in gasoline formulations, it complicates the tabulation and comparison of petroleum statistics. In both EIA and most international trade statistics, finished gasoline and blendstocks are treated as separate products, and as reported in EIA statistics, large volumes of finished gasoline are now produced from blendstocks by local "blenders," rather than by more centralized "refiners." In addition, the volume of refinery production of gasoline and blendstock is now systematically lower than consumption of finished gasoline, because up to 10 percent of the volume of gasoline sold at retail can be made up of ethanol that is blended into gasoline after it leaves the refinery.

Figure II-~~5283~~ - U.S. Gasoline Consumption, Production, and Net Exports: Historical and Forecast

Although EIA's Annual Energy Outlook does not include separate forecasts of gasoline exports and imports, that same agency's *Short Term Energy Outlook* projects that U.S. gasoline exports will continue to rise through 2020 (EIA, 2019).²³⁵⁵ Combined with EIA's reference case forecast in the AEO 2019, the forecasts of declining U.S. gasoline consumption and rising net exports of refined petroleum products suggest that the United States will remain a growing net exporter of refined petroleum products—including gasoline—through nearly 2040. In turn, this suggests that any increase in domestic gasoline consumption resulting from this final rule is likely to low anticipated growth in U.S. exports, rather than prompting growth in domestic refining and associated upstream emissions.

Regional patterns of U.S. gasoline consumption, refining, and trade also suggests that redirecting U.S. gasoline exports to domestic markets is likely to be an important source of additional supply to meet any increase in U.S. consumption stemming from this final rule. The nation's East Coast (which comprises the Energy Information Administration's Production and Distribution District 1, or PADD 1) currently accounts for about 32 percent of U.S. gasoline consumption, but has historically produced significantly less than gasoline than it consumes. As Figure VI-2 below shows, the gap between consumption and local supply within PADD1 has recently narrowed, as gasoline production along the East Coast has increased rapidly in recent years, while shipments into the region from the remainder of the U.S. and foreign imports (which come mostly from Canada) declined. In June 2019, however, press reports suggested that that one of the largest East Coast refineries (Philadelphia Energy Solutions, which represents some 28 percent of East Coast refining capacity) would be closed.²³⁵⁶ At the same time, construction of new refineries continues to be hindered by the density of population concentrations and commercial development along the nation's East Coast, casting doubt on the potential for continued increases in local gasoline refining and supply within PADD 1.

²³⁵⁵ AEO does not forecast gasoline refining, imports, or exports separately, instead reporting them as part of total refined petroleum products.

²³⁵⁶ Seba, E. (2019, July 5). Philadelphia refinery closing reverses two years of U.S. capacity gains. Retrieved September 19, 2019, from Reuters: <https://www.reuters.com/article/us-usa-refinery-blast-capacity/philadelphia-refinery-closing-reverses-two-years-of-u-s-capacity-gains-idUSKCN1U0283>.

Figure II-5384 - U.S. East Coast (EIA PADD 1) Gasoline Production, Consumption, Transfers from Rest of U.S., and Net Exports

As a consequence, it seems likely that at least in the near term, any increase in gasoline consumption along the Nation's East Coast in response to this rule would be supplied primarily by Gulf Coast refineries or increased foreign imports, rather than from increased production in East Coast refineries. Pipelines available to transport refined petroleum products from Gulf Coast refineries to the East Coast may also face capacity limitations, in which case most of any increase in gasoline consumption there would need to be met by increased imports from abroad. Over the longer term, however, it is possible that increases in East Coast gasoline consumption could be met partly by expanded refining activity within the region.

The West Coast, which includes Nevada and Arizona (EIA's PADD 5), currently accounts for 168 percent of U.S. gasoline consumption. Almost all of the gasoline consumed in that region is also refined within it, although small volumes are shipped into Arizona from neighboring PADDs by pipeline, and small volumes are also exported to Latin America by tanker. The West Coast is relatively isolated from other U.S. sources of refined gasoline by long transportation distances and limited pipeline capacity, while import terminals for crude petroleum are relatively numerous, and it therefore appears more likely that marginal increases in gasoline consumption from the rule will be met from increases in local (i.e., within-PADD) refining. Figure VI-3 shows that this has been the case in recent decades, as growth in gasoline production within PADD 5 throughout that period has closely paralleled growth in local consumption, while net exports have remained minimal.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure II-5485 - U.S. West Coast (EIA PADD 5) Gasoline Production, Consumption, Transfers from Rest of U.S., and Net Exports

The central region of the United States (PADDs 2-4) accounts for the remaining 52 percent of current U.S. gasoline consumption, while producing about three-quarters of the nation's gasoline and blendstock. Although as Figure VI-4 shows the central region was a minor net exporter of gasoline as recently as 2007, it now exports some 800,000 barrels per day of gasoline and blendstock, and has accounted for virtually all of the recent growth in U.S. exports of these two categories of refined products. Recent press reports indicate that firms are currently making significant new investments to add refining capacity on the Gulf Coast to process the growing supply of U.S. shale oil (Douglas, 2019), and with the projected future decline in U.S. consumption, any additional gasoline refined there is likely to increase U.S. exports. Thus, future increases in gasoline consumption in the central region of the U.S. of the magnitude likely to result from adopting these final standards is expected to be met by diverting gasoline exports to domestic consumption, even in the absence of additional refinery investments.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure II-5586 - U.S. Central Region (EIA PADDs 2-4) Gasoline Production, Consumption, Transfers to Rest of U.S., and Net Exports

Table II-170Table I-27 below compares recent changes in gasoline consumption and various sources of supply for these three U.S. regions during the recent period (2012-18) when gasoline consumption has generally increased. As it shows, recent increases in consumption along the U.S. East Coast have been supplied by increased production within the region. As noted previously, however, it appears likely that production capacity there will contract significantly in the near term, and that future increases in consumption will need to be met from foreign imports or shipments from other U.S. regions. As the table also shows, recent increases in gasoline production in the Midwest and Gulf Coast region have been adequate to supply increased consumption within the region as well as major increases in foreign exports and shipments to other U.S. regions. Finally, increased consumption on the Nation's West Coast appears to have been met via a combination of increased production within the region and drawdowns of previously accumulated inventories (not shown in the table).

At the national level, where net shipments among regions necessarily cancel one another (resulting in the zero entry for Net Receipts from Other PADDs shown in the table), recent increases in production have been sufficient to meet increased domestic consumption, while simultaneously enabling a major increase in exports. This suggests that from the nationwide aggregate perspective, incremental increases in domestic gasoline consumption resulting from this rule could be met by a reduction in U.S. exports of domestically-refined gasoline to other nations, accompanied by increases in shipments from the Midwest and Gulf Coast regions to the nation's East and West Coasts.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Table II-~~170243~~ - Recent Changes in Gasoline Consumption, Production, Imports and Exports by Region of the U.S.

Region	PADD	Gasoline Consumption, 2018		Changes, 2012-18 (000 Bbl.)				
		000 Bbl.	% of U.S. Total	Consumption	Production	Imports	Exports	Net Receipts from Other PADDs
East Coast	1	1,179,054	32%	67,206	134,201	225	1,227	-41,265
Midwest and Gulf Coast	2-4	1,910,047	52%	102,039	255,675	-787	165,069	48,389
West Coast	5	582,267	16%	54,573	14,470	805	8,575	-7,124
Entire U.S.	Total	3,671,368	100%	223,818	404,346	243	174,871	0

To summarize, based on changes in the various sources of supply that have accompanied recent changes in consumption within different regions of the U.S., the agencies anticipate that:

- Most of any marginal increases in U.S. gasoline consumption resulting from this rule that occur on the East Coast of the U.S. is likely to be met in the near term by increased transfers from other regions of the U.S. or higher foreign imports, and possibly by expanded refining activity in the longer term;
- Most of any marginal increases in U.S. gasoline consumption resulting from this rule that occur on the West Coast is likely to be supplied by increased gasoline refining within that region; and
- Most or all of any marginal increase in U.S. gasoline consumption resulting from this rule that occurs in the Central region is likely to be supplied by redirecting foreign exports to supply markets within that region.

With these expectations and acknowledging the uncertainty surrounding them, the agencies have concluded that assuming 50 percent of any increase in U.S. gasoline consumption will lead to increased domestic refining activity—and thus to increases in domestic refinery emissions—continues to be reasonable, and perhaps even overstates the expected increase in domestic refinery emissions. In particular, the agencies find that assuming 50 percent is more reasonable than assuming that either none or 100 percent of any change in gasoline consumption will be translated into changes in domestic gasoline refining. Thus, the agencies have elected to continue to employ the 50 percent assumption in their central analysis, and to examine the sensitivity of its results to varying this fraction over the entire possible range, from zero to 100 percent.

(ii) Changes in Crude Oil Supply to Domestic Refineries

The agencies also re-evaluated their assumption that 90 percent of the increase in crude petroleum refined in the U.S. to produce additional gasoline consumed as a result of this rule would be imported from abroad (thus resulting in increased emissions for its storage at import terminals, and transportation to domestic refineries), while the remaining 10 percent would be produced domestically (thus resulting in emissions from its extraction, local storage, and transportation to U.S. refineries). As discussed in more detail below, the agencies conclude that domestic petroleum production responds primarily to technological innovations, investments in exploration and development of new domestic sources of oil, and variation in the world price of petroleum, rather than to U.S. demand for refined products such as gasoline. As a

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

consequence, they conclude that any increase in gasoline consumption attributable to this final rule is unlikely by itself to have a significant effect on domestic petroleum production, and that their previous assumption continues to be reasonable.

U.S. oil production is primarily a function of development opportunities identified during prior exploration programs, innovations in the technological for drilling and extracting crude petroleum, producer's expectations regarding future world petroleum prices, and the U.S. tax and regulatory situations surrounding petroleum exploration and production. Crude oil is a fungible, non-perishable commodity, and can usually be transported among local oil markets around the globe at some cost. As a consequence, the price of oil in a U.S. domestic market such as Texas is highly correlated with its price in markets located in Northern Europe, the Far East, and the Middle East.

In contrast, U.S. gasoline consumption depends on a broad array of factors that overlap only partially with the determinants of U.S. crude petroleum production. These include domestic economic growth and its consequences for transportation demand, current and future vehicle fuel economy, gasoline prices, excise and sales taxes levied on gasoline, technological and cultural changes, vehicle prices, and the evolution of transportation systems and the built environment.

As a consequence, changes in U.S. consumption and supply of petroleum products will primarily be reflected in changes the destinations of domestically produced and imported crude petroleum, rather than in changes in their production volumes. To the extent that changes in U.S. gasoline demand lead to changes in the volume refined domestically (the subject of the previous analysis), increased refining activity is thus likely to be reflected in a shift in U.S. imports or exports of crude oil, rather than in a change in U.S. production of crude oil. Instead, any effect of this rule on U.S. crude oil production would arise primarily from the impact of increased domestic gasoline demand on global oil prices, which will be limited by the fact that U.S. gasoline demand accounts for a relatively small share of total global demand for petroleum products, and by the response of global supply to any upward pressure on prices. Thus, any effect of this rule on U.S. petroleum production is likely to be extremely modest.²³⁵⁷

Localized and temporary changes in domestic production might arise in response to capacity limitations or transportation bottlenecks associated with particular regions or refineries, which could temporarily create markets for higher-priced crude oil. However, these situations would normally be localized and prevail for only a limited time. At the same time, the effects of any change in domestic petroleum consumption on world oil prices would be attenuated, because as indicated previously the impact of increased domestic consumption would be felt on prices and volumes supplied in the much larger global petroleum market, rather than confined to the smaller U.S. market. Any resulting changes in global oil prices and petroleum production would inevitably be small when viewed on a world scale, and likely to prompt only minimal responses in U.S. petroleum supply.

As one indication of the likely minimal impacts of higher U.S. gasoline consumption on U.S. production of crude petroleum, EIA's *Annual Energy Outlook 2018* included a side case called "No New Efficiency Requirements," which included a freeze on U.S. fuel economy standards beginning in 2020. Although this scenario does not correspond exactly to either the agencies' earlier proposal or this final rule,

²³⁵⁷ U.S. gasoline consumption currently accounts for about 9% of total global demand for refined petroleum products, and the AEO 2019 reference case projects that this will decline to 6% by the year 2035, and remain at that level through 2050. These figures are calculated from AEO 2019 Reference Case, Tables 11 and 21, available at https://www.eia.gov/outlooks/aeo/tables_ref.php.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

comparing its results to those from the AEO 2018 reference case illustrates the insensitivity of domestic crude oil production to increases in gasoline consumption, as represented in EIA's National Energy Modeling System (NEMS).

Figure VI-5 below presents such a comparison, showing historical trends in U.S. gasoline consumption and petroleum production, and comparing their projected future trends in the AEO 2018 Reference Case and No New Efficiency Requirements alternative. As the figure illustrates, the large increase in U.S. gasoline consumption under the latter scenario relative to the Reference Case is accompanied by an almost indiscernible change in U.S. crude petroleum production, for exactly the reasons described above.

Figure II-5687 - Projected U.S. Gasoline Consumption and Crude Oil Production under AEO 2018 Reference and no New Efficiency Standards Scenario Cases

The agencies conclude that in the context of the current global petroleum market, increases in U.S. gasoline demand on the scale likely to result from this final rule are unlikely to produce changes in the market that prompt a significant increase in domestic petroleum production. Instead, they are likely to affect mainly the destinations and uses of crude petroleum—including refining gasoline within the U.S.—that is already being supplied to the global market. As a consequence, we have elected to retain our previous assumption that any increase in domestic gasoline refining that occurs as a consequence of adopting this final rule is unlikely by itself to lead to a significant increase in domestic crude oil production or in the associated upstream emissions. Specifically, the agencies continue to assume that 10 percent of any increase in domestic gasoline refining would utilize increased U.S. production of crude petroleum.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The agencies chose to model upstream emissions in order to generate full fuel cycle emissions—using GREET for the upstream component and MOVES for the downstream component—because each alternative has varying levels of fuel consumption, and the specific gallons of gasoline, diesel, E85, and other fuels evaluated in today’s rule will lead to different tailpipe and upstream emission outcomes.

While it may be fair to characterize MOVES and GREET as partial equilibrium models rather than general equilibrium models, the agencies did not make any modifications to the MOVES or GREET emission factors themselves. Changes in emission results were initiated through changes in fleet composition or activity, especially changes in vehicle miles travelled as well as vehicle sales and population. Other changes were made to average vehicle mass and road load coefficients such as aerodynamic drag and rolling resistance corresponding to the various regulatory alternatives. Each alternative consists of a package of technology changes, so a particular technology change was not modeled alone and would need to be evaluated separately to quantify incremental changes. Please consult the FRIA for quantified impacts for the technology packages laid out by alternative.

d) *How did the agencies estimate and value health impacts from changes in air quality*

Emissions of criteria air pollutants and airborne toxics by light-duty vehicles increase atmospheric concentrations of these pollutants, and by doing so increase human exposure to levels of air pollution that can lead to a variety of adverse health impacts, ranging from minor temporary health impacts to premature death. An extensive catalog of the potential health impacts that can result from varying levels of exposure to criteria pollutants and airborne toxics appears in above in Section VI.C.3.b. In turn, these health impacts impose real economic costs on individuals they affect, in the form of medical care expenses, missed work or reduced participation in social and recreational activities, the value of diminished productivity or quality of life, and even premature death, among others. Conversely, by reducing the scope, frequency, or intensity of these health impacts, lowering emissions of criteria pollutants and airborne toxics can reduce these costs, thus providing important economic benefits.

The agencies’ analyses estimates changes in the population-wide incidence of selected health impacts, as well as changes in the aggregate value of health damage costs, likely to result from the changes in emissions of criteria air pollutants projected to result from this final rule and the alternative that were considered. As with other impacts of the final rule and alternatives, these are measured as changes from a baseline that is represented by the adoption of the Augural CAFE standards and the extension of EPA’s CO₂ s updated estimates for these values, providing a more precise accounting of physical impacts and costs and benefits of the standards, and also directly responds to comments, as discussed below.²³⁵⁸

Many commenters expressed concern over the health impacts from increased GHG emissions and criteria pollutants. The American Lung Association et al. stated “Today, nearly 40 percent of Americans—more than 124 million—live in communities in nonattainment for ozone and particulate matter, with many

²³⁵⁸ See EPA, Office of Air and Radiation, Office of Air Quality Planning and Standards, *Technical Support Document, Estimating the Benefit per Ton of Reducing PM_{2.5} Precursors from 17 Sectors*, February 2018, available at https://www.epa.gov/sites/production/files/2018-02/documents/sourceapportionmentbpttsd_2018.pdf.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

residents impacted more severely by local pollution sources, including near-road pollution.... Near-road pollution has been found to increase asthma attacks in children, cardiovascular health impacts, impaired lung function and premature death Reducing VOC emissions will help reduce the burden of these carcinogens on many communities, especially those living or working near these roadways.”²³⁵⁹ As discussed in this Section, the agencies agree with these statements and have considered health effects as part of the analysis for today’s rule. The Institute for Policy Integrity stated “the agencies fixate on alleged on-road fatality effects while arbitrarily ignoring the mortalities, morbidities, and other welfare effects associated with emissions.”²³⁶⁰ As described in this Section, in the analysis for this rule, the agencies estimate both air quality-related fatalities and their costs, in addition to the agencies’ analysis on vehicle-related fatalities. Many public commenters also expressed concern for health issues associated with increased pollutants and emissions. The agencies carefully considered these comments and provided additional analysis to consider health impacts, as described below.

The estimated health impacts reflect the nationwide baseline level of emissions of each pollutant, an assumed geographic distribution of increased emissions, the resulting changes in concentrations of criteria pollutants at various locations nationwide (some of which reflect accumulations of emissions, while others are chemical by-products formed in atmospheric reactions), increased exposure of the U.S. population to unhealthful concentrations of each pollutant, and the consequences of increased exposure for the aggregate frequency of each health impact. The agencies’ analysis assumes that the increases in upstream and vehicle emissions are distributed in proportion to current emissions associated with fuel supply and vehicle use. This is consistent with the way EPA estimates health impacts and health damage costs for the refining and on-road mobile sources sectors, since those are estimated by assuming an increase in emissions from those sectors that is distributed in proportion to current emissions from each one, and estimating the resulting changes in accumulations of air pollutants, population exposure, health impacts, and associated health damage costs. The accompanying estimates of per-ton damage costs apply unit values to the increased frequency of each health effect, representing the dollar costs or estimated willingness-to-pay to avoid its occurrence, and combine the results to estimate total damage costs.

EPA analysts utilize a large volume of underlying data, a number of intermediate calculations, and many simplifying assumptions to develop these estimates of health impacts and health damage costs per ton of additional emissions, and discussing these in detail is well beyond the scope of this rule. These underlying data, assumptions, and calculations are described in detail in the document that reports the values used for the agencies’ analysis.²³⁶¹ EPA quantifies health impacts and damage costs for emissions from 17 separate sectors of U.S. economic activity, and reports values for increases in premature mortality and the combined costs of damages from premature mortality and various other health impacts per ton of PM_{2.5}, nitrate, and sulfate emissions.²³⁶² These values include high and low estimates of both premature mortality and health damage costs, which primarily reflect alternative published estimates of the premature mortality impact of PM_{2.5} emissions.²³⁶³ Alternative values are also reported for 3 percent and 7 percent discount rates;

²³⁶¹ See EPA, Office of Air and Radiation, Office of Air Quality Planning and Standards, *Technical Support Document, Estimating the Benefit per Ton of Reducing PM_{2.5} Precursors from 17 Sectors*, February 2018, available at https://www.epa.gov/sites/production/files/2018-02/documents/sourceapportionmentbptsd_2018.pdf.

²³⁶² Premature mortality includes deaths that occur before the normally expected life span of persons with specified demographic characteristics.

²³⁶³ Estimated willingness to pay to avoid premature death accounts for 98% of the total health damage costs included in these estimates; see EPA, p. 10.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

discounting affects the values because of the delay (or “latency period”) between exposure to air pollution and the development of some health impacts, most notably premature deaths.

The agencies’ analysis uses those values for the petroleum refining sector (sector 15) to represent impacts resulting from emissions that occur during the fuel production and distribution process (upstream emissions), and those for the on-road mobile source sector (sector 13) to represent the impacts of emissions resulting from car and light truck use. The agencies apply EPA’s estimates of per-ton increases in premature mortality and health damage costs for these sectors to their estimates of changes in nationwide total emissions of PM_{2.5}, nitrogen oxides (NO_x), and sulfur dioxide (SO₂) from the fuel supply process and from car and light truck use.

[Table II-171](#)~~Table I-28~~ and [Table II-172](#)~~Table I-29~~ below report values the agencies used in the estimates of premature mortality impacts and total health damage costs per ton of emissions to analyze the consequences of this final rule. The results for this analysis are provided in Section VII of this rule. The dollar values reported in the tables below differ slightly from those reported in the underlying source, because they have been adjusted from the 2015\$ used in that source to the 2018\$ used throughout this analysis. Values for intervening years were interpolated from those shown in the tables, and values for the year 2030 shown in the tables were assumed to prevail for years beyond 2030. The agencies’ central analysis of the rule uses averages of the low and high values shown in each table, while the low and high values themselves are used in the sensitivity analyses described in Section VII of this rule.

Full-scale photochemical modeling provides the needed spatial and temporal detail to more precisely estimate changes in ambient levels of these pollutants and their associated impacts on human health and welfare. This modeling provides insight into the uncertainties associated with the use of benefit-per-ton estimates. The agencies conducted a photochemical modeling analysis for the Final EIS using the same methods as in the previous CAFE Final EISs^{2364,2365} and the HD Fuel Efficiency Standards Phases 1 and 2 Final EISs.^{2366,2367} The air quality modeling and health effects analysis focused on ozone and fine particulate matter equal to or less than 2.5 microns in diameter (PM_{2.5}). As indicated in the Draft EIS, the agencies performed photochemical air quality modeling based on the inputs and emissions forecasts used in the Draft EIS. Consistent with prior rulemakings and as described in the scoping notice, to accommodate the substantial time required to complete the air quality modeling analysis, NHTSA proposed to initiate air quality modeling before the inputs and emissions forecasts for the Final EIS were finalized.²³⁶⁸ NHTSA received no public comments in response to the scoping notice addressing this analytical approach, and the agency proceeded accordingly. Therefore, NHTSA used the inputs and emissions forecasts for the Proposed Action and alternatives as stated in the Draft EIS for the analysis in this final rulemaking. For additional information on the scoping notice and comments received, *see* Section X.

Some stakeholders submitted comments about the agencies' use of underlying NPRM modeling to conduct the photochemical modeling; for example, NCDEQ recognized the agencies statement that there was not sufficient time to collect the modeling, but stated that they "strongly believe that the inputs and results should be readily available for public comment before the EIS and rulemaking are finalized."²³⁶⁹ Those comments are addressed in Section X and in the FEIS accompanying this rule. As part of EDF's alternative examination of the CAFE model and inputs, EDF utilized the same EPA benefit-per-ton method the agencies utilized for the final rule (discussed further below) to estimate health effects due to criteria pollutant emissions, concluding that the proposal would increase premature mortality due to increases in particulate matter emissions. EDF stated that these results indicated that the potential impacts of the rule are large, and accordingly, "NHTSA and EPA must conduct detailed and thorough emission, photochemical and health effects modeling to quantify the effect of this or any other proposal to relax the CAFE and CO₂ standards and increase upstream emissions."²³⁷⁰

The agencies estimated air quality changes and health-related benefits at the national scale based on a detailed analysis of air quality and health effects throughout the contiguous 48 states. Different regions of the country could experience either a net increase or a net decrease in emissions because of the rule, depending on the relative magnitude of the changes in emissions from decreased fuel economy, decreased

vehicle use, and increased fuel production and distribution under each alternative. The EIS air quality analysis addresses regional differences using grid-based air quality modeling and analysis techniques, which account for local and regional differences in emissions and many of the other factors (such as meteorology and atmospheric processes) that affect air quality and the resulting health effects at any given location. This air quality modeling analysis is intended as a screening application of both the Community Multiscale Air Quality (CMAQ) model and the Environmental Benefits Mapping and Analysis Program (BenMAP) tool for the purposes of quantifying and comparing the air quality and health-related benefits.

To examine and quantify the air quality and health-related benefits associated with implementing the final CAFE standards for MY 2021–2026 light-duty vehicles, the agencies performed a national-scale photochemical air quality modeling and health benefit assessment with the following key steps:

- Preparing emission inventories
- Modeling air quality
- Assessing air quality–related health impacts

The following widely used tools were used for the air quality and health effects assessment:

- Sparse-Matrix Operator Kernel Emissions (SMOKE) processing tool (version 3.7) to prepare model-ready emissions.
- CMAQ model (version 5.2.1) to quantify air quality changes for the different fuel economy alternatives.
- Environmental Benefits Mapping and Analysis Program—Community Edition (BenMAP-CE) tool (version 1.4) to assess the health-related impacts of the simulated changes in air quality.

The national-scale modeling analysis employed the standard CMAQ continental modeling domain. The horizontal resolution of the grid for this modeling domain is 36 kilometers (22.4 miles). Air quality and health-related impacts were calculated for each grid cell in the entire contiguous United States (48 states). Although the modeling domain does not include all 50 states, nearly all of the affected emissions and population are included in the domain; therefore, the results are expected to represent those for a national-scale analysis. The agencies applied the CMAQ model for an annual simulation period using meteorological inputs for a base year of 2011.

The agencies performed modeling for 2035 (although the emission inputs represented a variety of different projection years, including 2030, 2035, and 2040, based on best available data). As in the Draft EIS, the agencies chose 2035 for analysis of the various fuel economy alternatives because a large proportion of vehicles in operation are expected to meet the level of the standards set forth by 2035. EPA provided up-to-date, projected, national-scale emissions data for 2040 for motor vehicles and for 2030 for all other sources. The emissions were processed for the 36-kilometer (22.4-mile) resolution modeling domain using SMOKE. The resulting model-ready inventories contain emissions for all criteria pollutants (as required for photochemical modeling) for multiple source categories (sectors), including on-road mobile sources, non-road mobile sources (e.g., construction equipment, locomotives, ships, and aircraft), electric generating unit (EGU) point sources, non-EGU point sources, area sources, and biogenic sources.

Following preparation of baseline emissions inventories, the baseline emissions for the light-duty vehicle portion of the on-road mobile emissions and the relevant upstream categories were replaced with data reflecting the alternatives analyzed in the Draft EIS. As discussed above, NHTSA calculated national

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

estimates of on-road emissions for these vehicle classes for 2035, including both downstream and upstream emissions.

The agencies then applied CMAQ, using the emissions specific to each alternative. The simulated difference in air quality between the Draft EIS No Action Alternative and each action alternative represents the change in air quality associated with that alternative. Following the application of CMAQ, the agencies processed the CMAQ outputs for input to the BenMAP-CE health effects analysis tool, and used BenMAP-CE to estimate the health impacts and monetized health-related benefits associated with the changes in air quality simulated by CMAQ for each of the action alternatives. The BenMAP-CE tool includes health impact functions, which relate a change in the concentration of a pollutant with a change in the incidence of a health endpoint. BenMAP-CE also calculates the economic value of health impacts. For this study, the health effects analysis considered the effects of ozone and PM_{2.5}. The PM_{2.5} analysis includes sulfate and nitrate particulates (secondary PM_{2.5}) formed from emissions of SO₂ and NO_x, respectively. BenMAP-CE does not estimate health impacts associated with changes in directly emitted sulfur dioxide (SO₂), carbon monoxide (CO), and other emissions. Health effects were calculated at the 36-kilometer scale (grid cell size) and aggregated nationally to determine overall impact.

Figure II-57~~Figure I-10~~ shows the components of the air quality modeling and health-related benefits analysis. Note that both the emissions and meteorological inputs are used by SMOKE.

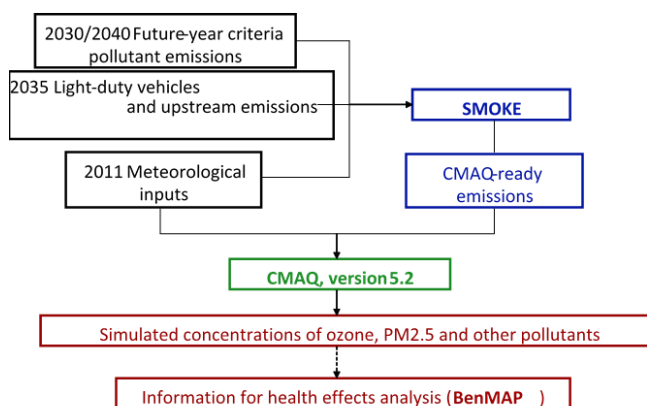

Figure II-57~~88~~ - Diagram of Air Quality Modeling and Health-Related Benefit Analysis

Discussion of the photochemical modeling results is presented in the FEIS accompanying this final rule.

E. Compliance example walk-through

To illustrate the CAFE model's simulation of a manufacturer's potential response to fuel prices and new standards, the NPRM provided an example of how the preliminary version of the model showed, on a year-by-year basis, how GM could potentially respond to a set of CAFE standards, starting from MY 2016 (the latest year for which the agencies were able to develop a full and detailed characterization of the fleet of vehicles produced for sale in the U.S. at the time of publishing the NPRM). Although no analysis that does not rely heavily on a manufacturer's confidential product planning information can, with high fidelity, predict what that manufacturer *will* do, the CAFE model, by realistically reflecting product planning

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

considerations in a detailed year-by-year context, can describe a course that manufacturer *could* realistically take. Indeed, when manufacturers provide information to the agencies, they often emphasize year-by-year plans. Although such information is typically considered confidential business information (CBI), public comments by the Alliance illustrate the concept for a hypothetical manufacturer. Although the illustration includes credit carry-back (aka borrowing) that most manufacturers have a history of avoiding, the illustration clearly demonstrates that the Alliance views product planning as a year-by-year exercise:

Figure II-5889 – Alliance Illustration of a Hypothetical OEM’s Compliance Pathway²³⁷¹

Like the peer reviewers who examined the model’s simulation of technology application and compliance, automakers have been widely supportive of the CAFE model’s approach of year-by-year analysis informed by product planning realities. For example, Toyota commented, “The preamble correctly notes that manufacturers try to keep costs down by applying most major changes mainly during vehicle redesigns and more modest changes during product refresh, and that redesign cycles for vehicle models can range from six to ten years, and eight to ten-years for powertrains... This appreciation for standard business practice enables the modeling to capture more accurately the way vehicles share engines, transmissions, and platforms. There are now more realistic limits placed on the number of engines and transmissions in a powertrain portfolio which better recognizes manufacturers must manage limited engineering resources and control supplier, production, and service costs.”²³⁷²

The CAFE model’s year-by-year approach to estimating manufacturers’ potential responses to standards and fuel prices is consistent with EPCA/EISA’s requirement that CAFE standards be set at the maximum feasible levels for each fleet (passenger car and light truck) in each model year. Some commenters correctly observe that the CAA (which provides no direction regarding tailpipe CO₂ emissions

²³⁷¹ NHTSA-2018-0067-12073, at 28.

²³⁷² NHTSA-2018-0067-12098, at 6.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

standards) does not require such a year-by-year determination, but suggest, further, that EPA should refrain from making use of year-by-year analysis. In particular, CBD et. al. commented as follows:

Furthermore, the Volpe model and association [sic] tools are not designed in accordance with EPA's independent statutory authority under Clean Air Act Section 202. The Volpe and OMEGA models have an overarching difference in their architecture—one where the Volpe modeling approach is designed to match NHTSA's statutory authority, but not EPA's. The EPCA requirements drive the design of the Volpe model, in that it performs a year-by-year analysis in order to demonstrate that NHTSA is meeting its EPCA obligations. As a result, the Volpe model attempts to simulate for each manufacturer, by year, their refresh and redesign cadence across their vehicle platforms and then predict a manufacturer's technology deployment decision-making process for each platform. But under the Clean Air Act, EPA is not required to demonstrate that standards are set at the maximum feasible level year-by-year, as EPCA explicitly requires for NHTSA.²³⁷³

Although CBD is correct that the CAA does not *require* a year-by-year determination or year-by-year analysis, CBD wrongly claims that the CAFE model's modeling approach is not "in accordance" with the CAA. CBD's claim is analogous to saying "just say you want to drive across the country; don't bother looking at a map." As the NPRM demonstrated, the CAFE model can be used to simulate compliance with CO₂ standards. That the model follows a year-by-year approach to doing so simply means that it takes greater pains to describe realistic pathways forward from a known model year. Manufacturers are by no means the only stakeholders to recognize that product planning is actually a year-by-year process. Supporting its comments on the agencies' proposal, CARB provided a study by Roush Industries, focusing on a potential design pathway for the Toyota RAV4.²³⁷⁴ While this report, which was cited by CARB in its comments, asserted the agencies' modeling underestimated fuel consumption benefits and overestimated costs, Roush, like the Alliance, clearly interpreted the question of realism as a year-by-year question, as illustrated by the following chart in Roush's report:

²³⁷³ NHTSA-2018-0067-12000, Appendix A, at 24-25.

²³⁷⁴ Rogers, G., "Technical Review of: The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks, Final Report." Roush Industries. October 25, 2018. See CARB, NHTSA-2018-0067-11984.

Figure II-5990 – Roush Industries Illustration (for CARB) of RAV4 Fuel Economy Pathway²³⁷⁵

While a year-by-year representation is essential to the estimation of pathways that individual manufacturers could realistically take to apply technologies to specific vehicle models, the CAFE model also accounts for a range of other important engineering and product planning considerations. For example, among specific vehicle models, engines and transmissions are often shared, and a given vehicle design platform may encompass a range of different specific vehicle models. This means not every configuration of every vehicle model can be as optimized for fuel economy as if each could be considered in isolation. This isn't to say that such optimization is technologically impossible, but rather to say that the resources involved in such optimization would be financially impracticable. Moreover, CAFE and CO₂ standards apply to fleets, not specific products. This means, for example, that if a given engine is shared among both passenger cars and light trucks, changes made to that engine in response to one fleet's standard will impact products in the other fleet. Consistent with the fact that CAFE and CO₂ compliance applies to fleets on a year-by-year basis, the CAFE model explicitly accounts for sharing among specific model/configurations when simulating year-by-year compliance. The Roush report's authors "have not performed a complete fleet-compliance simulation."²³⁷⁶ Therefore, even notwithstanding differences in estimates of redesign schedules and technology efficacy and costs, Roush's analysis of the RAV4 is highly idealized. As discussed below, together with inputs based on Toyota's actual MY 2017 production, the CAFE model represents the RAV4 as encompassing multiple configurations, spanning both the passenger car and light truck regulatory classes, all on a common vehicle platform that includes several other vehicle models, and some RAV4s sharing engines with some Camrys. Compared to estimating the *potential* to apply technology to a handful of

²³⁷⁵ Rogers, G., "Technical Review of: The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks, Final Report," at 26. Roush Industries. October 25, 2018. See CARB, NHTSA-2018-0067-11984.

²³⁷⁶ *Ibid.* at 6.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

specific model/configurations in isolation, analysis that accounts for manufacturers' *actual* production considerations produces more realistic results.

Nothing about the CAA discourages realism in regulatory analysis, and even if the CAA did so, the CAFE model can easily be run for isolated model years, or run in a manner that otherwise ignores practical limits on development and manufacturing complexity.²³⁷⁷ EPA elected to use the CAFE model as designed because doing so produces a more realistic basis to estimate regulatory impacts. EPA considers its use of the CAFE model entirely consistent with all CAA and other statutory and other requirements governing the agency's development of motor vehicle CO₂ emissions standards which, unlike criteria pollutant standards, are specified on a year-by-year basis, and inherently involve the entirety of manufacturers' vehicles and fleets.

Of course, like any other model, the CAFE model used for the NPRM had room for improvement. As discussed above, the agencies have responded to public comments by making changes to some aspects of the CAFE model itself. Only a few such changes, all of which are discussed above in greater detail, impact the CAFE model's simulation of manufacturers' application of fuel-saving technologies. Among these, three are especially important: First, the model now uses a more "open" application of its technology "decision trees." While the primary objective of this change is to make the model's cost accounting more transparent (by recasting costs as absolute rather than incremental), it also makes the model somewhat more likely to identify and apply any highly cost-effective yet comparatively "advanced" combinations of technology. Second, the model introduces a "cost per credit" metric for comparing available opportunities to add specific technologies to specific vehicles.²³⁷⁸ As discussed above and in the summary of the sensitivity analysis conducted for today's notice, changing from the NPRM's "effective cost" metric to this new "cost per credit" metric leads the model to, at least for the combination of inputs in today's central analysis, more frequently select less costly technology pathways than more costly pathways, at least when simulating compliance with CO₂ standards. Third, the CAFE model can now extend its explicit simulation of manufacturers' technology application well into the future. Today's analysis extends this explicit simulation through model year 2050. Because today's reference case input estimates include continued increases in fuel prices alongside continued ("learning"-related) reductions in technology costs, extending the explicit simulation shows manufacturers making significant voluntary improvement in the longer term (e.g., after MY 2035), even if CAFE and CO₂ remain unchanged.

The agencies have also revised most of the inputs to the CAFE model, both to respond to comments and to better reflect an ever-changing world. Sections appearing above discuss changes to model inputs, such as the analysis fleet, technology-related inputs, and fuel prices. Many of these changes are important to the model's simulated application of fuel-saving technology. Updating the analysis fleet from a MY 2016 to a MY 2017 basis ensures that fuel economy and CO₂ improvements manufacturers *actually* realized by adding technologies between those model years is accounted for, and ensures that changes in product offerings and production volumes between those model years are also accounted for. With this update, the agencies also more fully accounted for compliance credits accumulated prior to the MYs represented

²³⁷⁷ Idealized simulation of compliance with a hypothetically isolated model year could be accomplished by, when running the model, setting the various "start" and "end" years to the same value. Sharing of engines and transmission among different model/configurations could be ignored by, in the CAFE model's "market" input file, assigning each engine, transmission, and vehicle platform to a single model/configuration (e.g., such that each of the six versions of the RAV4 is on its own vehicle platform, and uses a dedicated engine and transmission).

²³⁷⁸ Notable comments on this metric appear at NHTSA-2018-0067-12039, Appendix, pp. 28-34, and at NHTSA-2018-0067-12108, Appendix B, pp. 66-70.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

explicitly in today's analysis. Some manufacturers have accumulated large volumes of such credits, and are able to apply those credits well past MY 2016, and to trade them to other manufacturers. Updated vehicle simulations correct errors and make use of additional engine performance estimates (i.e., engine efficiency "maps"), and cost estimates for some technologies reflect additional data and consideration of comments. Also, fuel prices in the forecast used for today's analysis are somewhat higher than those used for the NPRM; by itself, this change makes the model tend to show larger and more widespread voluntary fuel economy increases and accompanying CO₂ emissions reductions, although this increased tendency is countered by the impact of changing to the "cost per credit" metric.

The following example will illustrate the model's behavior when simulating compliance with CO₂ standards. While the example focuses on the baseline CO₂ standards and on a specific manufacturer (Toyota), and highlights a specific vehicle model (the Toyota RAV4), results for other scenarios, manufacturers, and vehicle models reflect application of the same logic. Because this example begins with the MY 2017 fleet, and does not make use of manufacturers' product plans (which the agencies have historically treated as confidential business information, today's analysis cannot and does not fully reflect manufacturers' actual product design decisions, even in the short term. Nevertheless, the analysis yields a realistic and detailed characterization of a path each manufacturer could take in response to a given set of standards and other input estimates (e.g., of technology costs and fuel prices).

As discussed above, the model considers all models and model/configurations produced for sale in the U.S. by a given manufacturer. The Toyota Camry and Tundra are examples of specific Toyota passenger car and light truck models, Toyota produces a range of configurations (e.g., with different engines) of each of these vehicle models, and inputs to the CAFE model ensure that each such configuration is accounted for. CAFE model output files show the progressive application of technology to each model/configuration over time under each regulatory alternative. Here, focusing on different versions of one model, the RAV4, illustrates the process and results.

The RAV4 is one of the vehicle models included in a vehicle platform that also includes the Camry, Corolla, Prius, Lexus CT 200h, Lexus NX 200t, and Lexus NX 300h. As mentioned above, the CAFE model reflects the agencies' assumption that significant changes to vehicle structures or materials will most practicably be applied throughout a vehicle platform as models within the platform are redesigned. Within this platform, the CAFE model identifies the Corolla LE, at more than 180,000 units produced in MY 2017, as the most likely "leader" for such changes. Inputs to today's analysis also show that most of the RAV4s produced for the U.S. in MY 2017 shared a 2.5L naturally aspirated 4-cylinder gasoline engine with many Camrys. The CAFE model identifies the Camry as the leader for new versions of that engine. The same inputs show many RAV4s shared a 6-speed automatic transmission with a range of other vehicle models, including the Avalon, Camry, Lexus ES 350, Highlander, Lexus NX 200t, and the CAFE model identifies the Camry as the most likely leader for changes to this transmission. Model inputs also show other RAV4s shared a different 6-speed automatic transmission with the Lexus NX 200t, and the CAFE model identifies the RAV4 as the most likely leader for changes to this transmission. Finally, the MY2017 RAV4 also included two "strong" (power split) hybrid-electric versions (SE and XLE). Although these shared an engine with other Toyota hybrids (Avalon, Camry, Lexus ES 300h and NX 300h), the CAFE model reflects the agencies' assumption that it could be practicable to "split off" plug-in (or fuel cell) configurations rather than necessarily replace all strong hybrids sharing an engine with PHEVs, BEVs, or FCVs.

Inputs for today's analysis have Toyota redesigning the RAV4 every five years, starting with MY 2019, and freshening the model 2-3 years after each redesign. Given this design cycle, and all the other inputs to today's analysis, the CAFE model shows that under the baseline CO₂ standards, Toyota could

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

potentially make changes to the RAV4 summarized in the table that follows. The first changes occur in 2019, with Toyota improving aerodynamics of the hybrid RAV4s, and with the conventional RAV4s inheriting a new high compression ratio (HCR) engine introduced with the MY 2018 redesign of the Camry, and also adding 8-speed automatic (A8) transmissions,²³⁷⁹ improved accessories (IACC), and tires with reduced rolling resistance (ROLL20). With the MY 2024 redesign, all versions of the RAV4 receive further aerodynamic improvements (AERO20) and “Level 1” mass reduction, engine friction reduction (EFR) is applied to the HCR engine the non-hybrid versions share with the Camry, and secondary axle disconnect (SAX) is applied to the non-hybrid versions of the RAV4. With the MY 2027 freshening, Toyota applies low-drag brakes to all the RAV4s. The MY 2029 redesign does not make any powertrain changes, but applies more significant mass reduction (MR3) to all RAV4s. In MY 2039, Toyota replaces the hybrid RAV4 SE and XLE with 200-mile (BEV200) and 300-mile (BEV300) electric vehicle, respectively.

²³⁷⁹ While it is not necessary for the compliance simulation to produce real predictions of manufacturer product designs, only plausible ones, these changes to the RAV4 did in fact occur during the 2019 redesign.

This progressive application of technology to the RAV4 produces a series of emission reductions shown in the following table (and, though not shown, corresponding fuel economy improvements). The table also shows the progression of CO₂ targets for these vehicles, reflecting the fact that targets are higher for the hybrid and conventional AWD versions of the RAV4, classified as light trucks, than for the FWD RAV4s classified as passenger cars. Also notably, the conventional RAV4s never achieve their respective CO₂ emissions targets. This merely reflects the fact that credits for reducing A/C refrigerant leakage apply at the fleet level rather than on a per-vehicle basis and, in any event, Toyota can respond by improving CO₂ levels enough among enough other vehicle models that Toyota's overall average CO₂ levels comply with Toyota's overall requirements, taking into account the potential application of compliance credits.

*Bold type indicates hybrid versions of RAV4 are replaced by BEV versions in 2039.

These CO₂ values could be converted to equivalent fuel economy levels by multiplying their reciprocals by 8887 grams per gallon (e.g., $8887 \text{ g/gal} \times 1/(144 \text{ g/mi}) = 62 \text{ mpg}$), differences in compliance provisions are such that results would be offset from actual fuel economy levels under CAFE standards. When simulating compliance with CAFE or CO₂ standards, the CAFE model reports both fuel economy and CO₂ targets and achieved levels, even when the model is “enforcing” compliance with only one of these sets of standards. When simulating compliance with baseline CO₂ standards, results for the example discussed here show the following fuel economy targets and achieved levels for the RAV4.

Table-II-~~175248~~ - Estimated RAV4 Target/Achieved FE Levels (mpg) under Modeled Response to Baseline CO₂ Standards

*Bold type indicates hybrid versions of RAV4 are replaced by BEV versions in 2039.

The progressive application of technology also produces increases (and some eventual decreases) in costs. For each RAV4 configuration, the following table shows costs beyond MY 2017 technology, in 2018 dollars. The conventional RAV4s incur a significant cost increase in MY 2019, primarily for the new HCR engine inherited from the Camry. Costs continue to increase through MY 2029 as additional technology accumulates, with another significant increase for MR4 in MY 2029. After MY 2029, technology costs for conventional RAV4s gradually decline through MY 2050, in response to ongoing learning. In MY 2039, the BEV200 RAV4 is *less* expensive than the HEV RAV4 it replaces, leading this version's cost to drop by about \$500 between MY 2033 and MY 2034, and with learning, to fall quickly well below this version's MY 2017 cost. Conversely, the BEV300 RAV4 introduced in MY 2039 is about \$950 more expensive than the MY 2038 hybrid RAV4 it replaces, and even with learning, the BEV300 remains more expensive through MY 2050 than the hybrid RAV4. These BEVs are not needed for compliance; the model shows Toyota could introduce them because, if battery costs continue to decline while gasoline prices continue to increase, BEVs could eventually become attractive on an economic basis.

*Bold type indicates hybrid versions of RAV4 are replaced by BEV versions in 2039.

As mentioned above, by making sufficient improvements to other vehicle models, Toyota could refrain from making the conventional RAV4s meet their CO₂ emissions targets. More broadly, Toyota can also use compliance credits to cover compliance gaps. The CAFE model accounts for the potential to transfer compliance credits between the passenger car (PC) and light truck (LT) fleets. The model also accounts for the potential to apply credits from prior model years (i.e., credits that have been “banked” or, equivalently, “carried forward”), including compliance credits earned prior to MY 2017. These aspects of the model interact with the model’s accounting for multiyear planning—that is, the potential that a manufacturer, depending on its product design cadence and on the progression of standards, might apply “extra” technology in some model years in order to facilitate compliance in later model years. For example, if a manufacturer is only redesigning 15% of its fleet volume in MY 2025, that manufacturer might be best off—even setting aside credit banking—applying some “extra” technology (i.e., technology that leads to overcompliance) as part of vehicle redesigns planned for MYs 2018-2024, and carrying that technology forward into MY 2025 when there are fewer opportunities available to reduce CO₂ emissions in new models. As shown in [Figure II-60](#) [Figure VI-74](#), in Toyota’s case, the model shows that Toyota could offset its light truck compliance gaps during MY 2017-2019 by applying compliance credits earned for light trucks prior to MY 2017. The graph also shows Toyota applying extra technology to its passenger car fleet during MYs 2018-2024 in order to comply with the MY 2025 passenger car standard, but also to carry forward compliance credits and use those credits to offset large compliance gaps for Toyota’s light truck fleet during MYs 2023-2027. After MY 2025, the model shows the effects of some technology continuing to be

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

inherited (especially during MYs 2026-2030) from prior MYs, of Toyota continuing to make voluntary improvements where economically attractive (like the MY 2039 RAV4 EV mentioned above), and of Toyota continuing to transfer compliance credits from the passenger car to the light truck fleet.²³⁸⁰

Figure II-6091 – Estimated CO₂ Requirements and Average Emission Rates for Toyota under Baseline CO₂ Standards

As the above figure shows, credit banking and transfers play an important role in Toyota’s simulated response to the standards. If exercised in a manner that sets aside credit banking, the CAFE model shows Toyota increasing its application of fuel-saving technologies through MY 2025, and carrying those improvements forward, such that Toyota’s overall average CO₂ emission rate is 16 g/mi lower in MY 2025 when credit banking is not accounted for, as illustrated by the next chart appearing below. Though not shown here, accounting for credit banking also impacts the simulation other OEMs’ compliance pathways, because inputs to today’s analysis assume that Toyota would likely not need to use all of its pre-2017 compliance credits before these credits expire in 2021, and that Toyota could therefore sell those older

²³⁸⁰ While the fleets (PC and LT) are shown separately for compliance purposes in this example, the ability to utilize credits from either fleet toward total model year compliance (in the current year, without caps or limits) means that the fleets for a manufacturer comply jointly in each model year.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***
 credits other manufacturers (e.g., FCA, VW). By accounting for credit banking, the CAFE model thereby avoids considerable potential understatement of future CO₂ emissions from light-duty vehicles.

Figure II-6192 - Impact of Credit Banking on Estimated Toyota CO₂ Emission Rates under Baseline CO₂ Standards

As indicated by the following chart, a failure to account for credit banking would also increase Toyota’s modeled per-vehicle costs by nearly \$1,000 in MY 2025. By accounting for credit banking, the CAFE model thus avoids considerable potential overstatement of compliance costs. Though not shown here, accounting for credit banking while also applying inputs that reflect Toyota’s ability to sell older credits to some other OEMs also enables the CAFE model to avoid overstatement of compliance costs for those OEMs.

Figure II-6293 - Impact of Credit Banking on Estimated Toyota Per-Vehicle Costs under Baseline CO₂ Standards

While the model’s simulation of manufacturers’ potential responses to CAFE standards applies the same inputs and analytical methods, it does so accounting for several important statutory and regulatory differences between CO₂ standards and CAFE standards, and for specific statutory direction regarding how CAFE standards are to be considered for purposes of setting standards at the maximum feasible levels in each model year. EPCA places specific limits on the amount of credit that can be transferred between fleets, and requires that domestic passenger cars meet minimum standards without applying credits. EPCA also requires that the determination of maximum feasible stringency set aside the potential to apply compliance credits or introduce new alternative fuel vehicles (include BEVs and FCVs, but not including plug-in HEVs) during the model years under consideration. Especially with standards that continue to become more stringent, applying these statutory constraints to the analysis leads the model to tend to show greater overcompliance with standards in earlier model years, because even setting aside the potential to carry forward or transfer credits, Toyota is likely to find it more practicable to apply some “extra” technology when redesigning vehicles during MYs 2017-2024 than to attempt to address MY 2025 standards by working with only vehicles scheduled to be redesigned in MY 2025. The model also tends to show greater overcompliance in later model years, because some of that extra technology from years leading up to the last year of stringency increases takes time to carry forward to ensuing model years. These aspects of the CAFE “standard setting” analysis are evident in the model’s solution for Toyota, shown in the following figure. With the use of credits set aside after MY 2020, Toyota overcomplies with light truck standards during MYs

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

2018-2023 in order to carry technology forward into MY 2025. Although Toyota only marginally overcomplies with MY 2025 standards, the inheritance of technology during MYs 2026-2029 contributes to increased overcompliance (which is to be expected given the degree of platform and powertrain sharing between the fleets). Continued increases in overcompliance after 2030 arise due to cost learning effects (especially for batteries) and increased fuel prices.

Figure II-6394 - Estimated CAFE Requirements and Levels for Toyota under Baseline CAFE Standards

VII. What does the analysis show, and what does it mean?

A. Impacts of the standards—final and alternatives

New CAFE and CO₂ standards will have a range of impacts. EPCA/EISA and NEPA require DOT to consider such impacts when making decisions about new CAFE standards, and the CAA requires EPA to do so when making decisions about new emissions standards. Like past rulemakings, today's announcement is supported by the analysis of many potential impacts of new standards. Today's rulemaking finalizes new standards through model year 2026. While the CAFE model explicitly estimates manufacturers responses to standards through model year 2050 and the associated impacts through calendar year 2089, today's rulemaking presents estimates of impacts on model years through MY 2029, including impacts through these vehicles' full useful lives (i.e., for MY 2029 vehicles, through 2068). Today's rulemaking also presents

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

estimates of overall impacts in each calendar year through 2050, accounting for all model years through 2050. The agencies of course do not *know* today what will actually come to pass decades from now under the new final standards or under any of alternatives under consideration. The analysis is intended less as a forecast, than as an assessment—reflecting the best judgments regarding many different factors—of impacts that *could* occur.²³⁸¹ As discussed below, the analysis was conducted using several defined alternatives to explore the sensitivity of this assessment to a variety of potential changes in key analytical inputs (e.g., fuel prices).

This section summarizes various impacts of the final standards and other regulatory alternatives defined above. The no-action alternative provides the baseline relative to which all impacts are shown. Because the final standards (and the other alternatives considered), being of a “deregulatory” nature, are less stringent than the no-action alternative, all impacts are directionally opposite to impacts reported in recent CAFE and CO₂ rulemakings. For example, while past rulemakings reported positive values for fuel consumption avoided under new standards, today’s rulemaking reports negative values, as fuel consumption is expected be somewhat greater under today’s new final standards than under standards defining the baseline no-action alternative. Reported negative values for avoided fuel consumption could also be properly interpreted as simply “additional fuel consumption.” Similarly, reported negative values for costs could be properly interpreted as “avoided costs” or “benefits,” and reported negative values for benefits could be properly interpreted as “forgone benefits” or “costs.” However, today’s rulemaking retains reporting conventions consistent with past rulemakings, anticipating that, compared to other options, doing so will facilitate review by most stakeholders.

Today’s analysis presents results for individual model years in two different ways. The first way is similar to past rulemakings and shows how manufacturers could respond in each model year under the new final standards and each alternative covering MYs 2021/2022-2026. The second, expanding on the information provided in past rulemakings, evaluates incremental impacts of new standards for each model year, in turn. In past rulemaking analyses, NHTSA modeled year-by-year impacts under the aggregation of standards applied in all model years, and EPA modeled manufacturers’ hypothetical compliance with a single model years’ standards in that model year. Especially considering multiyear planning effects, neither approach provides a clear basis to attribute impacts to specific standards first introduced in each of a series of model years. For example, of the technology manufacturers applied in MY 2017, some would have been applied even under the MY 2014 standards, and some were likely applied to position manufacturers toward compliance with (including credit banking to be used toward) MY 2018 standards. Therefore, of the impacts attributable to the model year 2017 *fleet*, only a portion can be properly attributed to the MY 2017 *standards*, and the impacts of the MY 2017 standards involve fleets leading up and extending well beyond MY 2016. Considering this, the final standards were examined on an incremental basis, modeling each new model year’s standards over the entire span of included model years, using those results as a baseline relative to which to measure impacts attributable to the next model year’s standards. For example, incremental costs attributable to the new standards for MY 2023 are calculated as follows:

$$COST_{New\ final,MY\ 2023} = (COST_{New\ final_through_MY\ 2023} - COST_{No-Action_through_MY\ 2023}) - (COST_{New\ final_through_MY\ 2022} - COST_{No-Action_through_MY\ 2022})$$

where

²³⁸¹ “Prediction is very difficult, especially if it’s about the future.” Attributed to Niels Bohr, Nobel Laureate in Physics.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

COST_{New final, MY 2023}: Incremental technology cost during MYs 2018-2029 and attributable to the new final standards for MY 2023.

COST_{New final, through MY 2022}: Technology cost for MYs 2018-2029 under new final standards through MY 2022.

COST_{New final, through MY 2023}: Technology cost for MYs 2018-2029 under new final standards through MY 2023.

COST_{No-Action, through MY 2022}: Technology cost for MYs 2018-2029 under no-action alternative standards through MY 2022.

COST_{No-Action, through MY 2023}: Technology cost for MYs 2018-2029 under no-action alternative standards through MY 2023.

Furthermore, today's analysis includes impacts on new vehicle sales volumes and the use (i.e., survival) of vehicles of all model years, such that standards introduced in a model year produce impacts attributable to vehicles having been in operation for some time. For example, as modeled here, standards for MY 2021 will impact the prices of new vehicles starting in MY 2017, and those price impacts will affect the survival of all vehicles still in operation in calendar years 2018 and beyond (e.g., MY 2021 standards impact the operation of MY 2007 vehicles in calendar year 2027). Therefore, while past rulemaking analyses focused largely on impacts over the useful lives of the explicitly modeled fleets, much of today's analysis considers all model years through 2029, as operated over their entire useful lives. For some impacts, such as on technology penetration rates, average vehicle prices, and average vehicle ownership costs, the focus was on the useful life of the MY 2029 fleet, as the simulation of manufacturers' technology application and credit use (when included in the analysis) continues to evolve after model year 2026, stabilizing by model year 2029.

Responding to comments recommending that the agencies present impacts on a calendar year basis, today's rulemaking does so, with the presented results extending through calendar year 2050, the last calendar year that includes an on-road fleet with all vehicle vintages represented.

Effects were evaluated from four perspectives: the social perspective, the manufacturer perspective, the private perspective, and the physical perspective. The social perspective focuses on economic benefits and costs, setting aside economic transfers such as fuel taxes but including economic externalities such as the social cost of CO₂ emissions. The manufacturer perspective focuses on average requirements and levels of performance (i.e., average fuel economy level and CO₂ emission rates), compliance costs, and degrees of technology application. The private perspective focuses on costs of vehicle purchase and ownership, including outlays for fuel (and fuel taxes). The physical perspective focuses on national-scale highway travel, fuel consumption, highway fatalities, and carbon dioxide and criteria pollutant emissions.

This analysis does not explicitly identify "co-benefits", as such a concept would include all benefits other than cost savings to vehicle buyers. Instead, it distinguishes between private benefits—which include economic impacts on vehicle manufacturers, buyers of new cars and light trucks, and owners (or users) of used cars and light trucks—and external benefits, which represent indirect benefits (or costs) to the remainder of the U.S. economy that stem from the final rule's effects on the behavior of vehicle manufacturers, buyers, and users. In this accounting framework, changes in fuel use and safety impacts resulting from the final rule's effects on the number of used vehicles in use represent an important component of its private benefits and costs, despite the fact that previous analyses have failed to recognize

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

these effects. The agencies' presentation of private costs and benefits clearly distinguishes between those that would be experienced by owners and users of cars and light trucks produced during previous model years and those that would be experienced by buyers and users of new cars and light trucks subject to the final standards. Moreover, it clearly separates these into benefits related to fuel consumption and those related to safety consequences of vehicle use. This is more meaningful and informative than simply identifying all impacts other than changes in fuel savings to buyers of new vehicles as "co-benefits."

For the social perspective, the following effects for model years through 2029 as operated through calendar year 2068 are summarized:

- Technology Costs: Incremental cost, as expected to be paid by vehicle purchasers, of fuel-saving technology beyond that added under the no-action alternative.
- Welfare Loss: Loss of value to vehicle owners resulting from incremental increases in the numbers of strong and plug-in hybrid electric vehicles (strong HEVs or SHEVs, and PHEVs) and/or battery electric vehicles (BEVs), beyond increases occurring under the no-action alternative.²³⁸² The loss of value is a function of the factors that lead to different valuations for conventional and electric versions of similar-size vehicles (e.g., differences in: travel range, recharging time versus refueling time, performance, and comfort).
- Pre-tax Fuel Savings: Incremental savings, beyond those achieved under the no-action alternative, in outlays for fuel purchases, setting aside fuel taxes.
- Mobility Benefit: Value of incremental travel, beyond that occurring under the no-action alternative.
- Lost New Vehicle Consumer Surplus: Value of incremental savings to new vehicle buyers due to cheaper vehicle prices.
- Implicit Opportunity Cost:²³⁸³ Value of other vehicle attributes forewent to apply technology to meet the standards.
- Refueling Benefit: Value of incremental reduction, compared to the no-action alternative, of time spent refueling vehicles.
- Non-Rebound Fatality Costs: Social value of additional fatalities, beyond those occurring under the no-action alternative, setting aside any additional travel attributable to the rebound effect.
- Rebound Fatality Costs: Social value of additional fatalities attributable to the rebound effect, beyond those occurring under the no-action alternative.
- Benefits Offsetting Rebound Fatality Costs: Assumed further value, offsetting rebound fatality costs internalized by drivers, of additional travel attributed to the rebound effect.
- Non-Rebound Non-Fatal Crash Costs: Social value of additional crash-related losses (other than fatalities), beyond those occurring under the no-action alternative, setting aside any additional travel attributable to the rebound effect.
- Rebound Non-Fatal Crash Costs: Social value of additional crash-related losses (other than fatalities) attributable to the rebound effect, beyond those occurring under the no-action alternative.

²³⁸² Through MY 2029, the "standard setting" analysis of CAFE standards sets aside the potential that manufacturers might by introduce new BEV (or FCV) vehicle models, but allows that the numbers of such vehicles produced might increase or decrease along with overall U.S. sales of new passenger cars and light trucks, and allows that additional BEV or FCV vehicle models might be introduced after MY 2029.

²³⁸³ This value is set to "0" for the central analysis.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- Benefits Offsetting Rebound Non-Fatal Crash Costs: Assumed further value, offsetting rebound non-fatal crash costs internalized by drivers, of additional travel attributed to the rebound effect.
- Additional Congestion and Noise (Costs): Value of additional congestion and noise resulting from incremental travel, beyond that occurring under the no-action alternative.
- Energy Security Benefit: Value of avoided economic exposure to petroleum price “shocks,” the avoided exposure resulting from incremental reduction of fuel consumption beyond that occurring under the no-action alternative.
- Avoided CO₂ Damages (Benefits): Social value of incremental reduction of CO₂ emissions, compared to emissions occurring under the no-action alternative.
- Other Avoided Pollutant Damages (Benefits): Social value of incremental reduction of criteria pollutant emissions, compared to emissions occurring under the no-action alternative.
- Total Costs: Sum of incremental technology costs, welfare loss, fatality costs, non-fatal crash costs, and additional congestion and noise costs.
- Total Benefits: Sum of pretax fuel savings, mobility benefits, refueling benefits, Benefits Offsetting Rebound Fatality Costs, Benefits Offsetting Rebound Non-Fatal Crash Costs, energy security benefits, and benefits from reducing emissions of CO₂, the CO₂ equivalent of other associated gases, and criteria pollutants.
- Net Benefits: Total benefits minus total costs.
- Retrievable Electrification Costs: The portion of HEV, PHEV, and BEV technology costs which can be passed onto consumers, using the willingness to pay analysis described above.
- Electrification Tax Credits: Estimates of the portion of HEV, PHEV, and BEV technology costs which are covered by Federal or State tax incentives.
- Irrecoverable Electrification Costs: The portion of HEV, PHEV, and BEV technology costs OEM’s must either absorb as a profit loss, or cross-subsidize with the prices of internal combustion engine (ICE) vehicles.
- Total Electrification Costs: Total incremental technology costs attributable to HEV, PHEV, or BEV vehicles.

For the manufacturer perspective, the following effects for the aggregation of model years 2017-2029 are summarized:

- Average Required Fuel Economy: Average of manufacturers’ CAFE requirements for indicated fleet(s) and model year(s).
- Percent Change in Stringency from Baseline: Percentage difference between averages of fuel economy requirements under no-action and indicated alternatives.
- Average Required Fuel Economy: Industry-wide average of fuel economy levels achieved by indicated fleet(s) in indicated model year(s).
- Percent Change in Stringency from Baseline: Percentage difference between averages of fuel economy levels achieved under no-action and indicated alternatives.
- Total Technology Costs (\$b): Cost of fuel-saving technology beyond that applied under no-action alternative.
- Total Civil Penalties (\$b): Cost of civil penalties (for the CAFE program) beyond those levied under no-action alternative.
- Total Regulatory Costs (\$b): Sum of technology costs and civil penalties
- Sales Change (millions): Change in number of vehicles produced for sale in U.S., relative to the number estimated to be produced under the no-action alternative.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- Revenue Change (\$b): Change in total revenues from vehicle sales, relative to total revenues occurring under the no-action alternative.
- Curb Weight Reduction: Reduction of average curb weight, relative to MY 2017.
- Technology Penetration Rates: MY 2030 average technology penetration rate for indicated ten technologies (three engine technologies, advanced transmissions, and six degrees of electrification).
- Average Required CO₂: Average of manufacturers' CO₂ requirements for indicated fleet(s) and model year(s).
- Percent Change in Stringency from Baseline: Percentage difference between averages of CO₂ requirements under no-action and indicated alternatives.
- Average Achieved CO₂: Average of manufacturers' CO₂ emission rates for indicated fleet(s) and model year(s).

For the private perspective, the following effects for the MY 2030 fleet are summarized:

- Average Price Increase: Average increase in vehicle price, relative to the average occurring under the no-action alternative.
- Implicit Opportunity Cost: The lost benefit of vehicle attributes that consumers prefer, which are sacrificed by manufacturers to comply with the standards.
- Welfare Loss (Costs): Average loss of value to vehicle owners resulting from incremental increases in the numbers of strong HEVs, PHEVs) and/or BEVs, beyond increases occurring under the no-action alternative. The loss of value is a function of the factors that lead to different valuations for conventional and electric versions of similar-size vehicles (e.g., differences in: travel range, recharging time versus refueling time, performance, and comfort).
- Ownership Costs: Average increase in some other costs of vehicle ownership (taxes, fees, financing), beyond increase occurring under the no-action alternative.
- Lost Consumer Surplus: Value of incremental savings to new vehicle buyers due to cheaper vehicle prices.
- Fuel Savings: Average of fuel outlays (including taxes) avoided over a vehicle's expected useful lives, compared to outlays occurring under the no-action alternative.
- Mobility Benefit: Average incremental value of additional travel over average vehicles' useful lives, compared to travel occurring under the no-action alternative.
- Refueling Benefit: Average incremental value of avoided time spent refueling over average vehicles' useful lives, compared to time spent refueling under the no-action alternative.
- Total Costs: Sum of average price increase, welfare loss, and ownership costs.
- Total Benefits: Sum of fuel savings, the mobility benefit, and the refueling benefit.
- Net Benefits: Total benefits minus total costs.

For the physical perspective, the following effects for model years through 2029 as operated through calendar year 2068 are summarized:

- Fuel Consumption, with rebound (billion gallons): Reduction of fuel consumption, relative to the no-action alternative, and including the rebound effect.
- Fuel Consumption, without rebound (billion gallons): Reduction of fuel consumption, relative to the no-action alternative, and excluding the rebound effect.
- Greenhouse Gases: Includes carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O), and values are reported separately for vehicles (tailpipe) and upstream processes (combining fuel

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

production, distribution, and delivery) and shown as reductions in carbon dioxide or its equivalent relative to the no-action alternative.

- **Criteria Pollutants:** Includes carbon monoxide (CO), volatile organic compounds (VOC), nitrogen oxides (NO_x), sulfur dioxide (SO₂) and particulate matter (PM), and values are shown as reductions relative to the no-action alternative.
- **Fuel Consumption:** Aggregates all fuels, with electricity, hydrogen, and compressed natural gas (CNG) included on a gasoline-equivalent-gallon (GEG) basis, and values are shown as reductions relative to the no-action alternative.
- **VMТ, with rebound (billion miles):** Increase in highway travel (as vehicle miles traveled), relative to the no-action alternative, and including the rebound effect.
- **VMТ, without rebound (billion miles):** Increase in highway travel (as vehicle miles traveled), relative to the no-action alternative, and excluding the rebound effect.
- **Fatalities, with rebound:** Increase in highway fatalities, relative to the no-action alternative, and including the rebound effect.
- **Fatalities, without rebound:** Increase in highway fatalities, relative to the no-action alternative, and excluding the rebound effect.
- **Health Effects:** Increase in the occurrence of a variety of health effects of criteria pollutant emissions, relative to the no-action alternative, and reported separately for tailpipe and upstream emissions.

Below, this section tabulates results for each of these four perspectives and does so separately for the new final CAFE and CO₂ standards. More detailed results are presented in the FRIA accompanying today's rulemaking, and additional and more detailed analysis of environmental impacts for CAFE regulatory alternatives is provided in the corresponding Final Environmental Impact Statement (FEIS). Underlying CAFE model output files are available (along with input files, model, source code, and documentation) on NHTSA's web site.²³⁸⁴ Summarizing and tabulating results for presentation here involved considerable "off model" calculations (e.g., to combine results for selected model years and calendar years, and to combine various components of social and private costs and benefits); tools Volpe Center staff used to perform these calculations are also available on NHTSA's web site.²³⁸⁵

While the National Environmental Policy Act (NEPA) requires NHTSA to prepare an EIS documenting estimating environmental impacts of the regulatory alternatives under consideration in CAFE rulemakings, NEPA does not require EPA to do so for EPA rulemakings. With CO₂ standards for each regulatory alternative being harmonized as practical with corresponding CAFE standards, environmental impacts of CO₂ standards should be directionally identical and similar in magnitude to those of CAFE standards. Nevertheless, in this section, following the series of tables below, today's announcement provides a more detailed analysis of estimated impacts of the new final CAFE and CO₂ standards. Results presented herein for the CAFE standards differ slightly from those presented in the FEIS; while, as discussed above, EPCA/EISA requires that the Secretary determine the maximum feasible levels of CAFE standards in manner that, as presented here, sets aside the potential use of CAFE credits or application of alternative fuels toward compliance with new standards, NEPA does not impose such constraints on any analysis presented in

²³⁸⁴ *Compliance and Effects Modeling System*, National Highway Traffic Safety Administration, <https://www.nhtsa.gov/corporate-average-fuel-economy/compliance-and-effects-modeling-system>.

²³⁸⁵ These tools, available at the same location, are scripts executed using R, a free software environment for statistical computing. R is available through <https://www.r-project.org/>.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***
corresponding FEISs, and the FEIS presents results of an “unconstrained” analysis that considers manufacturers’ potential application of alternative fuels and use of CAFE credits.

In terms of all estimated impacts, including estimated costs and benefits, the results of today’s analysis are different for CAFE and CO₂ standards. Differences arise because, even when the mathematical functions defining fuel economy and CO₂ targets are “harmonized,” surrounding regulatory provisions may not be. For example, while both CAFE and CO₂ standards allow credits to be transferred between fleets and traded between manufacturers, EPCA/EISA places explicit and specific limits on the use of such credits, such as by requiring that each domestic passenger car fleet meet a minimum CAFE standard (as discussed above). The CAA provides no specific direction regarding CO₂ standards, and while EPA has adopted many regulatory provisions harmonized with specific EPCA/EISA provisions (e.g., separate standards for passenger cars and light trucks), EPA has not adopted all such provisions. For example, EPA has not adopted the EPCA/EISA provisions limiting transfers between regulated fleet or requiring separate compliance by domestic and imported passenger car fleets. Such differences introduce variance between impacts estimated under CAFE standards and under CO₂ standards. Also, as mentioned above, Congress has required that new CAFE standards be considered in a manner that sets aside the potential use of CAFE credits and the potential additional application of alternative fuel vehicles (such as electric vehicles) during the model years under consideration. Congress has provided no corresponding direction regarding the analysis of potential CO₂ standards, and today’s analysis does consider these potential responses to CO₂ standards.

Tables in the remaining section summarize these estimated impacts for each alternative, considering the same measures as shown above for the final standards. For the final standards, social costs and benefits, private costs and benefits, and environmental and energy impacts were evaluated, and were done so separately for CAFE and CO₂ standards defining each regulatory alternative. Also, for the final standards, the compliance-related private costs and benefits were evaluated separately for domestic and imported passenger cars under CAFE standards but not under CO₂ standards because EPCA/EISA’s requirement for separate compliance applies only to CAFE standards.

Both the final standards and, all other alternatives involve standards less stringent than the no-action alternative. Therefore, as discussed above, incremental benefits and costs for each alternative are negative—in other words, each alternative involves forgone benefits and avoided costs. Environmental and energy impacts are correspondingly negative, involving forgone avoided CO₂ emissions and forgone avoided fuel consumption. For consistency with past rulemakings, these are reported as negative values rather than as additional CO₂ emissions and additional fuel consumption.

Like the NPRM and PRIA (and past rulemakings), today’s rulemaking and FRIA emphasize a “model year” perspective when reporting impacts. That is, for enough model years (here, through MY 2029) to extend beyond those when the estimated use of “banked” credits is reasonably likely to be sufficient to show the average manufacturer not achieving required CAFE or CO₂ levels, the presentation of results mainly considers the lifetime impacts attributable to vehicles produced in these model years. Because standards are actually enforced on a model year basis, this perspective aligns well with the consideration of impacts on manufacturers and new vehicle buyers. However, impacts on national energy consumption and the natural environment will involve all vehicles on the road in future years, including those produced after MY 2029. Therefore, similar to the approach followed in recent and past EISs (and today’s FEIS), today’s rulemaking also presents impacts on a “calendar year” basis—that is, summarizing overall impacts (i.e., including those attributable to vehicles produced after MY 2029) in each calendar year through 2050. As

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

discussed in below, the model year and calendar year perspectives draw on the same CAFE model outputs, but differ in the scope of those outputs included in summarized information.

As discussed above, more detailed results are available in the FRIA and FEIS accompanying today's rulemaking, as well as in underlying model output files posted on NHTSA's web site.

1. Average required fuel economy and CO₂ standard for PCs, LTs, and combined

The model fully represents the required CAFE and CO₂ levels for every manufacturer and every fleet. The standard for each manufacturer is based on the harmonic average of footprint targets (by volume) within a fleet, just as the standards prescribe. Unlike earlier versions of the CAFE model, the current version further disaggregates passenger cars into domestic and imported classes (which manufacturers report to NHTSA and EPA as part of their CAFE compliance submissions). This allows the CAFE model to more accurately estimate the requirement on the two passenger car fleets, represent the domestic passenger car floor (which must be exceeded by every manufacturer's domestic fleet, without the use of credits, but with the possibility of civil penalty payment), and allows it to enforce the transfer cap limit that exists between domestic and imported passenger cars, all for purposes of the CAFE program.

In calculating the achieved CAFE level, the model uses the prescribed harmonic average of fuel economy ratings within a vehicle fleet. Under an "unconstrained" analysis, or in a model year for which standards are already final, it is possible for a manufacturer's CAFE to fall below its required level without generating penalties because the model will apply expiring or transferred credits to deficits if it is strategically appropriate to do so. Consistent with current EPA regulations, the model applies simple (not harmonic) production-weighted averaging to calculate average CO₂ levels.

While the CAFE and CO₂ standards themselves are, as discussed in Section VI, inputs to the agencies' analysis, because the standards are attribute-based standards specified separately for passenger car and light truck fleets and applicable to average fuel economy and CO₂ levels, average requirements under these standards are analytical results, not analytical inputs. Also, because EPCA requires NHTSA to determine in advance minimum requirements that will be applicable to manufacturers' fleets of domestic passenger cars, these, too, are analytical results. The remainder of this section presents these results.

a) *Passenger car requirements*

As discussed in Section V, the final standards are different from the preferred alternative identified in the proposal.

We do not know yet with certainty what CAFE and CO₂ levels will ultimately be required of individual manufacturers, because those levels will depend on the mix of vehicles that each manufacturer produces for sale in future model years. Based on the market forecast of future sales used to examine the final standards, we currently estimate that the target functions shown above would result in the following average required fuel economy and CO₂ emissions levels for all manufacturers during MYs 2021-2026:

Table VII-1 - Average of OEMs' CAFE and CO₂ Requirements for Passenger Cars

Model Year	Avg. of OEMs' Requirements	
	CAFE (mpg)	CO ₂ (g/mi)
2017	39.0	220
2018	40.4	209

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

2019	41.9	197
2020	43.6	187
2021	44.2	178
2022	44.9	175
2023	45.6	171
2024	46.3	168
2025	47.0	167
2026	47.7	165

We emphasize again that the values in these tables are estimates, and not necessarily the ultimate levels with which each of these manufacturers will have to comply, for the reasons described above.²³⁸⁶

b) Light truck requirements

Again, while we do not know yet with certainty what CAFE and CO₂ levels will ultimately be required of individual manufacturers, because those levels will depend on the mix of vehicles that each manufacturer produces for sale in future model years, based on the market forecast of future sales used to examine today's proposed standards, we currently estimate that the target functions shown above would result in the following average required fuel economy and CO₂ emissions levels for individual manufacturers during MYs 2021-2026.

Table VII-2 - Average of OEMs' CAFE and CO₂ Requirements for Light Trucks

Model Year	Avg. of OEMs' Requirements	
	CAFE (mpg)	CO ₂ (g/mi)
2017	29.4	306
2018	30.0	293
2019	30.5	281
2020	31.1	268
2021	31.6	257
2022	32.1	253
2023	32.6	250
2024	33.1	248
2025	33.6	245
2026	34.1	240

We emphasize again the values in these tables are estimates and not necessarily the ultimate levels with which each of these manufacturers will have to comply for reasons described above.²³⁸⁷

²³⁸⁶MY2017 values reflect the agencies' analysis, which uses an analysis fleet developed using MY2017 compliance data as of summer 2019. The analysis does not reflect subsequent updates and corrections to manufacturers' MY2017 compliance data.

²³⁸⁷MY2017 values reflect the agencies' analysis, which uses an analysis fleet developed using MY2017 compliance data as of summer, 2019. The analysis does not reflect subsequent updates and corrections to manufacturers' MY2017 compliance data.

c) *Average of passenger car and light truck requirements*

Overall average requirements will depend, further, on the relative shares of passenger cars and light trucks in the new vehicle fleet. The agencies' analysis estimates future shifts in these shares as vehicles' average prices and fuel economy levels change, and as fuel prices also change. Resultant estimates of overall average requirements are as follows:

Table VII-3 - Average of OEMs' CAFE and CO₂ Requirements for Passenger Cars and Light Trucks Combined

Model Year	Avg. of OEMs' Requirements	
	CAFE (mpg)	CO ₂ (g/mi)
2017	33.8	261
2018	34.8	248
2019	35.7	236
2020	36.8	224
2021	37.3	214
2022	37.9	211
2023	38.5	207
2024	39.1	204
2025	39.8	202
2026	40.4	199

d) *Estimated average requirements for specific manufacturers*

Overall average requirements (e.g., reflecting both passenger car and light truck fleets) applicable to each manufacturer will depend on the mix (i.e., footprint distribution) of vehicles produced in each model year, and relative production shares of passenger cars and light trucks. Tables appearing below summarize estimated requirements through model year 2029. Estimates for specific fleets (e.g., domestic passenger cars, imported passenger cars, light trucks) are available in CAFE model output files accompanying today's rulemaking, as are estimates for each MYs 2030-2050.²³⁸⁸

²³⁸⁸ The model and all inputs and outputs supporting today's notice are available at <https://www.nhtsa.gov/corporate-average-fuel-economy/compliance-and-effects-modeling-system>.

2. Impacts on vehicle manufacturers

As mentioned above, impacts are presented from two different perspectives for today's final rule. From either perspective, overall impacts are the same. The first perspective, taken above in VI.A, examines overall impacts of the standards—i.e., the entire series of year-by-year standards—on each model year. The second perspective, presented here, provides a clearer characterization of the incremental impacts attributable to standards introduced in each successive model year. For example, the new final standards for MY 2023 are likely to impact manufacturers' application of technology in model years prior to MY 2023, as well as model years after MY 2023. By conducting analysis that successively introduces standards for each MY, in turn, isolates the incremental impacts attributable to new standards introduced in each MY, considering the entire span of MYs 1975-2029 and calendar years 2016-2069 included in the analysis that only considers the full series of successive MYs' standards. Tables appearing below summarize results as aggregated across these model and calendar years. Underlying model output files²³⁸⁹ report physical impacts and specific monetized costs and benefits attributable to each model year in each calendar (thus providing information needed to, for example, differentiate between impacts attributable to the MY 1975-2017 and MY 2018-2029 cohorts). The FRIA presents costs and benefits for individual model years (with MY's 1975-2017 in a single bucket) for the final standards.

a) *Industry average technology penetration rates*

The CAFE model tracks and reports technology application and penetration rates for each manufacturer, regulatory class, and model year, calculated as the volume of vehicles with a given technology divided by the total volume. The "application rate" accounts only for those technologies applied by the model during the compliance simulation, while the "penetration rate" accounts for the total percentage of a technology present in a given fleet, whether applied by the CAFE model or already present at the start of the simulation.

In addition to the aggregate representation of technology penetration, the model also tracks each individual vehicle model on which it has operated. Accordingly, the CAFE model produces a record for every model year and every alternative that identifies with which technologies the vehicle started the simulation and which technologies the same vehicle had at the conclusion of each model year. Interested parties may use these outputs to assess how the compliance simulation modified any vehicle that was offered for sale in MY 2017 in response to a given regulatory alternative.

²³⁸⁹ Available at <https://www.nhtsa.gov/corporate-average-fuel-economy/compliance-and-effects-modeling-system>.

b) Technology costs

For each technology that the model adds to a given vehicle, it accumulates cost. The technology costs are defined incrementally and vary both over time and by technology class, where the same technology may cost more to apply to larger vehicles as it involves more raw materials or requires different specifications to preserve some performance attributes. While learning-by-doing can bring down cost, and should reasonably be implemented in the CAFE model as a rate of cost reduction that is applied to the cumulative volume of a given technology produced by either a single manufacturer or the industry as a whole, in practice this notion is implemented as a function of time, rather than production volume. Thus, depending upon where a given technology starts along its learning curve, it may appear to be cost-effective in later years where it was not in earlier years. As the model carries forward technologies that it has already applied to future model years, it similarly adjusts the costs of those technologies based on their individual learning rates.

c) *Civil penalties*

The other costs that manufacturers incur as a result of CAFE standards are civil penalties resulting from non-compliance with CAFE standards. The CAFE model accumulates costs of \$5.50 per 1/10-MPG under the standard, multiplied by the number of vehicles produced in that fleet, in that model year. The model reports as the full “regulatory cost,” the sum of total technology cost and total fines by the manufacturer, fleet, and model year. As mentioned above, the relevant EPCA/EISA provisions do not also appear in the CAA, so this option and these costs apply only to simulated compliance with CAFE standards.

d) *Average prices, sales, and revenue changes*

In all previous versions of the CAFE model, the total number of vehicles sold in any model year, in fact the number of each individual vehicle model sold in each year, has been a static input that did not vary in response to price increases induced by CAFE standards, nor changes in fuel prices, or any other input to the model. The only way to alter sales, was to update the entire forecast in the market input file. However, in the 2012 final rule, the agencies included a dynamic fleet share model that was based on a module in the Energy Information Administration’s NEMS model. This fleet share model did not change the size of the new vehicle fleet in any year, but it did change the share of new vehicles that were classified as passenger cars (or light trucks). That capability was not included in the central analysis but was included in the uncertainty analysis, which looked at the baseline and final standards in the context of thousands of possible future states of the world. As some of those futures contained extreme cases of fuel prices, it was important to ensure consistent modeling responses within that context. For example, at a gasoline price of \$7/gallon, it would be unrealistic to expect the new vehicle market’s light truck share to be the same as the future where gasoline cost \$2/gallon. The current model has slightly modified, and fully integrated, the dynamic fleet share model. Every regulatory alternative and sensitivity case considered for this analysis reflects a dynamically responsive fleet mix in the new vehicle market.

While the dynamic fleet share model adjusts unit sales across body styles (cars, SUVs, and trucks), it does not modify the total number of new vehicles sold in a given year. The CAFE model now includes a separate function to account for changes in the total number of new vehicles sold in a given year (regardless of regulatory class or body style), in response to certain macroeconomic inputs and changes in the average new vehicle price. The price impact is modest relative to the influence of the macroeconomic factors in the model. The combination of these two models modify the total number of new vehicles, the share of passenger cars and light trucks, and, as a consequence, the number of each given model sold by a given manufacturer. However, these two factors are insufficient to cause large changes to the composition of any of a manufacturer’s fleets. In order to change significantly the mix of models produced within a given fleet, the CAFE model would require a way to trade off the production of one vehicle versus another both within a manufacturer’s fleet and across the industry. While the agencies have experimented with fully-integrated consumer choice models, their performance has yet to satisfy the requirements of a rulemaking analysis.

Above, Section VI discusses at length the sales model the agencies have applied in the analysis supporting today’s rulemaking.

*The change in MSRP may not match the change in technology costs reported in other tables. The change in MSRP noted here will include shifts in the average value of a vehicle, before technology application, due to the dynamic fleet share model (more light trucks are projected under the augural standards than the proposed standards, and light trucks are on average more expensive than passenger cars), in addition to the price changes from differential technology application and civil penalties, reported elsewhere.

e) *Labor*

As discussed in Section VI the analysis includes estimates of impacts on U.S. auto industry labor, considering the combined impact of changes in sales volumes and changes in outlays for additional fuel-saving technology. Note: This analysis does not consider the possibility that potential new jobs and plants attributable to increased stringency will not be located in the United States, or that increased stringency will not lead to the relocation of current jobs or plants to foreign countries. Compared to the no-action alternative (i.e., the baseline standards), the new final standards (alternative 1) and other regulatory alternatives under consideration all involve reduced regulatory costs expected to lead to reduced average vehicle prices and, in turn, increased sales. While the increased sales slightly increase estimated U.S. auto sector labor hours, because producing and selling more vehicles uses additional U.S. labor, the reduced outlays for fuel-saving technology slightly reduce estimated U.S. auto sector labor hours, because manufacturing, integrating, and selling less technology means using less labor to do so. Of course, this is technology that may not otherwise be produced or deployed were it not for regulatory mandate, and the additional costs of this technology would be borne by a reduced number of consumers given reduction in sales in response to increased prices. Today's analysis shows the negative impact of reduced mandatory technology outlays outweighing the positive impact of increased sales. However, both of these underlying factors are subject to uncertainty. For example, if fuel-saving technology that would have been applied under the baseline standards is more likely to have come from foreign suppliers than estimated here, less of the forgone labor to manufacture that technology would have been U.S. labor. Also, if sales would be more positively impacted by reduced vehicle prices than estimated here, correspondingly positive impacts on U.S. auto sector labor could be magnified. Alternatively, if manufacturers are able to deploy technology to improve vehicle attributes that new car buyers prefer to fuel economy improvements, both technology spending and vehicle sales would correspondingly increase.

The labor utilization analysis was focused on automotive labor because adjacent labor utilization factors and consumer spending factors for other goods and services are uncertain and difficult to predict. How direct labor changes may affect the macro economy and possibly change employment in adjacent industries were not considered. For instance, possible labor changes in vehicle maintenance and repair were not considered, nor were changes in labor at retail gas stations considered. Possible labor changes due to raw material production, such as production of aluminum, steel, copper, and lithium were not considered, nor were possible labor impacts due to changes in production of oil and gas, ethanol, and electricity considered. Effects of how consumers could spend money saved due to improved fuel economy were not analyzed, nor were effects of how consumers would pay for more expensive fuel savings technologies at the time of purchase analyzed; either could affect consumption of other goods and services, and hence affect labor in other industries. The effects of increased usage of car-sharing, ride-sharing, and automated vehicles were not analyzed. How changes in labor from any industry could affect gross domestic product and possibly affect other industries as a result were not estimated.

Also, no assumptions were made about full-employment or not full-employment and the availability of human resources to fill positions. When the economy is at full employment, a fuel economy regulation is unlikely to have much impact on net overall U.S. labor utilization; instead, labor would primarily be shifted from one sector to another. These shifts in employment impose an opportunity cost on society, approximated by the wages of the employees, as regulation diverts workers from other activities in the economy. In this situation, any effects on net employment are likely to be transitory as workers change jobs (e.g., some workers may need to be retrained or require time to search for new jobs, while shortages in some sectors or regions could bid up wages to attract workers). On the other hand, if a regulation comes into effect during a period of high unemployment, a change in labor demand due to regulation may affect net

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

overall U.S. employment because the labor market is not in equilibrium. Schmalensee and Stavins point out that net positive employment effects are possible in the near term when the economy is at less than full employment due to the potential hiring of idle labor resources by the regulated sector to meet new requirements (e.g., to install new equipment) and new economic activity in sectors related to the regulated sector. In the longer run, the net effect on employment is more difficult to predict and will depend on the way in which the related industries respond to the regulatory requirements. For that reason, this analysis does not include multiplier effects but instead focuses on labor impacts in the most directly affected industries. Those sectors are likely to face the most concentrated labor impacts.

The tables presented below summarize these results for the final standards and other regulatory alternatives considered. While values are reported as thousands of person-years, changes in labor utilization would not necessarily involve the same number of changes in actual jobs, as auto industry employers may use a range of strategies (e.g., shift changes, overtime) beyond simply adding or eliminating jobs.

4. Impacts to society

As the CAFE model simulates manufacturer compliance with regulatory alternatives, it estimates and tracks a number of consequences that generate social costs. The most obvious cost associated with the program is the cost of additional fuel economy improving/CO₂ emissions reducing technology that is added to new vehicles as a result of the rule. However, the model does not inherently draw a distinction between costs and benefits. For example, the model tracks fuel consumption and the dollar value of fuel consumed. This is the cost of travel under a given alternative (including the baseline). The “cost” or “benefit” associated with the value of fuel consumed is determined by the reference point against which each alternative is considered. The CAFE model reports absolute values for the amount of money spent on fuel in the baseline, then reports the amount spent on fuel in the alternatives relative to the baseline. If the baseline standard were fixed at the current level, and an alternative achieved significantly greater mpg by 2025, the total expenditures on fuel in the alternative would be lower, creating a fuel savings “benefit.” This analysis uses a baseline that is more stringent than each alternative considered, so the incremental fuel expenditures are greater for the alternatives than for the baseline.

Other social costs and benefits emerge as the result of physical phenomena, like tailpipe emissions or highway fatalities, which are the result of changes in the composition and use of the on-road fleet. The social costs associated with those quantities represent an economic estimate of the social damages associated with the changes in each quantity. The model tracks and reports each of these quantities by: model year and vehicle age (the combination of which can be used to produce calendar year totals), regulatory class, fuel type, and social discount rate.

The full list of potential costs and benefits is presented in [Table VII-90](#) as well as the population of vehicles that determines the size of the factor (either new vehicles or all registered vehicles) and the mechanism that determines the size of the effect (whether driven by the number of miles driven, the number of gallons consumed, or the number of vehicles produced).

Table VII-90 - Social Costs and Benefits in CAFE Model

Cost/Benefit	Population	Mechanism
Technology Cost	New vehicles	Production volume
Maintenance/Repair	New vehicles	Production volume
Implicit Opportunity Cost	New vehicles	Production volume, fuel economy
Relative Value Loss	New vehicles	Production volume
Pre-Tax Fuel Savings	All Vehicles	Gallons
Fuel Tax Revenue	All Vehicles	Gallons
Mobility Benefit	New vehicles	Miles
Lost New Vehicle Consumer Surplus	New Vehicles	Production volume
Implicit Opportunity Cost	New Vehicles	Production volume
Refueling Time Value	All Vehicles	Miles, fuel economy
Energy Security Cost	All Vehicles	Gallons
Congestion	All Vehicles	Miles
Accidents	All Vehicles	Miles
Noise Costs	All Vehicles	Miles

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Cost/Benefit	Population	Mechanism
Fatality Risk Value	All Vehicles	Miles, fleet mix, vehicle mass
Non-Fatal Risk Value	All Vehicles	Miles, fleet mix, vehicles mass
Fatalities	All Vehicles	Miles, fleet mix, vehicle mass
Non-Fatal Injuries	All Vehicles	Miles, fleet mix, vehicle mass
CO Damages	All Vehicles	Miles, Gallons
NO _x Damages	All Vehicles	Miles, Gallons
SO ₂ Damages	All Vehicles	Miles, Gallons
PM Damages	All Vehicles	Miles, Gallons
CO ₂ Damages	All Vehicles	Gallons

(1) *Total fleet size and VMT*

The CAFE model carries a complete representation of the registered vehicle population in each calendar year, starting with an aggregated version of the most recent available data about the registered population for the first year of the simulation. In this analysis, the first model year considered is MY 2017, and the registered vehicle population enters the model as it appeared at the end of calendar year 2016. The initial vehicle population is stratified by age (or model year cohort) and regulatory class—to which the CAFE model assigns average fuel economies based on the reported regulatory class industry average compliance value in each model year (and class). Once the simulation begins, new vehicles are added to the population from the market data file and age throughout their useful lives during the simulation, with some fraction of them being retired (or scrapped) along the way. For example, in calendar year 2018, the new vehicles (age zero) are MY 2018 vehicles (added by the CAFE model simulation and represented at the same level of detail used to simulate compliance), the age one vehicles are MY 2017 vehicles (added by the CAFE model simulation), and the age two vehicles are MY 2016 vehicles (inherited from the registered vehicle population and carried through the analysis with less granularity). This national registered fleet is used to calculate annual fuel consumption, vehicle miles traveled (VMT), pollutant emissions, and safety impacts under each regulatory alternative.

In support of prior CAFE rulemakings, the CAFE model accounted for new travel that results from fuel economy improvements that reduce the cost of driving. The magnitude of the increase in travel demand is determined by the rebound effect. In both previous versions and the current version of the CAFE model, the amount of travel demanded by the existing fleet of vehicles is also responsive to the rebound effect (representing the price elasticity of demand for travel)—increasing when fuel prices decrease relative to the fuel price when the VMT on which our mileage accumulation schedules were built was observed. Since the fuel economy of those vehicles is already fixed, only the fuel price influences their travel demand relative to the mileage accumulation schedule and so is identical for all regulatory alternatives.

While the average mileage accumulation per vehicle by age is not influenced by the rebound effect in a way that differs by regulatory alternative, three other factors influence total VMT in the model in a way that produces different total mileage accumulation by regulatory alternative. The first factor is the total industry sales response: new vehicles are both driven more than older vehicles and are more fuel efficient (thus producing more rebound miles). To the extent that more (or fewer) of these new models enter the vehicle fleet in each model year, total VMT will increase (or decrease) as a result. The second factor is the dynamic fleet share model. The fleet share influences not only the fuel economy distribution of the fleet, as light trucks are less efficient than passenger cars on average, but the total miles are influenced by fact that light trucks are driven more than passenger cars as well. Both of the first two factors can magnify the influence of the rebound effect on vehicles that go through the compliance simulation (MY 2017 – 2050) in the manner discussed above. The third factor influencing total annual VMT is the scrappage model. By modifying the retirement rates of on-road vehicles under each regulatory alternative, the scrappage model either increases or decreases the lifetime miles that accrue to vehicles in a given model year cohort.

In addition to dynamically modifying the total number of new vehicles sold, a dynamic model of vehicle retirement, or scrappage, has also been implemented. The model implements the scrappage response by defining the instantaneous scrappage rate at any age using two functions. For ages less than 30, instantaneous scrappage is defined as a function of vehicle age, new vehicle price, fuel prices, cost per mile of driving (the ratio of fuel price and fuel economy), and GDP growth rate. For ages greater than 30, the instantaneous scrappage rate is a simple exponential function of age. While the scrappage response does not

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

affect manufacturer compliance calculations, it impacts the lifetime mileage accumulation (and thus fuel savings) of all vehicles. Previous CAFE analyses have focused exclusively on new vehicles, tracing the fuel consumption and social costs of these vehicles throughout their useful lives; the scrappage effect also impacts the registered vehicle fleet that exists when a set of standards is implemented.

For a given calendar year, the retirement rates of the registered vehicle population are governed by the scrappage model. To the extent that a given set of CAFE or CO₂ standards accelerates or decelerates the retirement of vehicles, fuel consumption and social costs may change. The CAFE model accounts for those costs and benefits, as well as tracking all of the standard benefits and costs associated with the lifetimes of new vehicles produced under the rule. For more detail about the derivation of the scrappage functions, see Section VI.

(2) *Fuel consumption*

For every vehicle model in the market file, the model estimates the VMT per vehicle (using the assumed VMT schedule, the vehicle fuel economy, fuel price, and the rebound assumption). Those miles are multiplied by the volume for each vehicle. Fuel consumption is the product of miles driven and fuel economy, which can be tracked by model year cohort in the model. Carbon dioxide emissions from vehicle tailpipes are the simple product of gallons consumed and the carbon content of each gallon.

In order to calculate calendar year fuel consumption, the model needs to account for the inherited on-road fleet in addition to the model year cohorts affected by this new final rule. Using the VMT of the average passenger car and light truck from each cohort, the model computes the fuel consumption of each model year class of vehicles for its age in a given CY. The sum across all ages (and thus, model year cohorts) in a given CY provides estimated CY fuel consumption.

Because the model produces an estimate of the aggregate number of gallons sold in each CY, it is possible to calculate both the total expenditures on motor fuel and the total contribution to the Highway Trust Fund (HTF) that result from that fuel consumption. The Federal fuel excise tax is levied on every gallon of gasoline and diesel sold in the U.S., with diesel facing a higher per-gallon tax rate. The model uses a national perspective, where the State taxes present in the input files represent an estimated average fuel tax across all U.S. States. Accordingly, while the CAFE model cannot reasonably estimate potential losses to State fuel tax revenue from increasingly the fuel economy of new vehicles, it can do so for the HTF.

In addition to the tailpipe emissions of carbon dioxide, each gallon of gasoline produced for consumption by the on-road fleet has associated “upstream” emissions that occur in the extraction, transportation, refining, and distribution of the fuel. The model accounts for these emissions as well (on a per-gallon basis) and reports them accordingly.

(3) *Safety*

Earlier versions of the CAFE model accounted for the safety impacts associated with reducing vehicle mass in order to improve fuel economy. In particular, NHTSA’s safety analysis estimated the additional fatalities that would occur as a result of new vehicles getting lighter, then interacting with the on-road vehicle population. In general, taking mass out of the heaviest new vehicles improved safety outcomes, while taking mass from the lightest new vehicles resulted in a greater number of expected highway fatalities. However, the change in fatalities did not adequately account for changes in exposure that occur as a result of increased demand for travel as vehicles become cheaper to operate. The current version of the model

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

resolves that limitation and addresses additional sources of fatalities that can result from the implementation of CAFE or CO₂ standards. These are discussed in greater detail in Section VI.

The agencies have observed that older vehicles in the population are responsible for a disproportionate number of fatalities, both by number of registrations and by number of miles driven. Accordingly, any factor that causes the population of vehicles to turn over more slowly will induce additional fatalities—as those older vehicles continue to be driven, rather than being retired and replaced with newer (even if not brand new) vehicle models. The scrappage effect, which delays (or accelerates) the retirement of registered vehicles, impacts the number of fatalities through this mechanism—importantly affecting not just new vehicles sold from model years 2017-2050 but existing vehicles that are already part of the on-road fleet. Similarly, to the extent that a CAFE or CO₂ alternative reduces new vehicle sales, it can slow the transition from older vehicles to newer vehicles, reducing the share of total vehicle miles that are driven by newer, more technologically advanced vehicles. Furthermore, newer vehicles are equipped with technologies that make driving safer not only safer for the occupants of newer vehicles, but also pedestrians, cyclists, and even occupants of other vehicles. Accounting for the change in vehicle miles traveled that occurs when vehicles become cheaper to operate leads to a number of fatalities that can be attributed to the rebound effect, independent of any changes to new vehicle mass, price, or longevity.

The CAFE model estimates fatalities by combining the effects discussed above. In particular, the model estimates the fatality rate per billion miles VMT for each model year vehicle in the population (the newest of which are the new vehicles produced that model year). This estimate is independent of regulatory class and varies only by year (and not vehicle age). The estimated fatality rate is then multiplied by the estimated VMT (in billions of miles) for each vehicle in the population and the product of the change in curb weight and the relevant safety coefficient, as in the equation below.

$$Fatalities = VMT * FatalityEstimate * (1 + ChangePer100Lbs * \frac{\Delta(CurbWeight, Threshold)}{100})$$

For the vehicles in the historical fleet, meaning all those vehicles that are already part of the registered vehicle population in CY 2017, only the model year effect that determines the “FatalityEstimate” is relevant. However, each vehicle that is simulated explicitly by the CAFE model, and is eligible to receive mass reduction technologies, must also consider the change between its curb weight and the threshold weights that are used to define safety classes. For vehicles above the threshold, reducing vehicle mass can have a smaller negative impact on fatalities (or even reduce fatalities, in the case of the heaviest light trucks). The “ChangePer100Lbs” depends upon this difference. The sum of all estimated fatalities for each model year vehicle in the on-road fleet determines the reported fatalities, which can be summarized by either model year or calendar year.

b) *Environmental impacts*

Today’s final rule directly involves the fuel economy and average CO₂ emissions of light-duty vehicles, and the final rule is expected directly and significantly to impact national fuel consumption and CO₂ emissions. Fuel economy and CO₂ emissions are closely related, so that it is expected the impacts on national fuel consumption and national CO₂ emissions will track in virtual lockstep with each other.

Today’s final rule does not directly involve pollutants such as carbon monoxide, smog-forming pollutants (nitrogen oxides and unburned hydrocarbons), fine particulate matter, or “air toxics” (e.g., formaldehyde, acetaldehyde, benzene). While today’s final rule is expected to impact such emissions indirectly (by reducing travel demand and accelerating fleet turnover to newer and cleaner vehicles on one

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

hand while, on the other, increasing activity at refineries and in the fuel distribution system), it is expected that these impacts will be much smaller than impacts on fuel use and CO₂ emissions because standards for these other pollutants are independent of those for CO₂ emissions.

Following decades of successful regulation of criteria pollutants and air toxics, modern vehicles are already vastly cleaner than in the past, and it is expected that new vehicles will continue to improve. For example, the following chart shows trends in new vehicles' emission rates²³⁹⁰ for volatile organic compounds (VOCs) and nitrogen oxides (NO_x)—the two motor vehicle criteria pollutants that contribute to the formation of smog.

Figure VII-1 - New Passenger Car Emission Rates Relative to 1975 Level – Smog-Forming Pollutants

Because new vehicles are so much cleaner than older models, it is expected that under any of the alternatives considered here for fuel economy and CO₂ standards, emissions of smog-forming pollutants would continue to decline nearly identically over the next two decades. The following chart shows estimated total fuel consumption, CO₂ emissions, and smog-forming emissions under the baseline and new final

²³⁹⁰ The emission rate is the rate at which a vehicle emits a given pollutant into the atmosphere. Tailpipe emission rates are expressed on a gram per mile basis. For example, driving 15,000 miles in a year, a vehicle with a 0.4 g/mi NO_x emission rate would emit 6,000 grams of NO_x.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

standards (CAFE standards—trends for CO₂ standards would be very similar), normalized to 2017 levels in order to allow the three to be shown together on a single chart:

Figure VII-2 - Annual Fuel Consumption and Emissions under Baseline and Final CAFE Standards

The following table summarizes relative differences between the baseline/augural and final standards:

Table VII-115 - Impact of New Final CAFE Standards on Annual Fuel Use and Emissions

Year	Fuel Use	CO ₂ Emissions	Smog-Forming Emissions
2020	0.3%	0.3%	0.0%
2025	2.3%	2.3%	0.0%
2030	4.5%	4.4%	0.4%
2035	6.1%	6.0%	1.0%
2040	7.1%	6.9%	1.4%
2045	8.2%	8.0%	1.8%
2050	9.4%	9.0%	2.2%

As indicated, the agencies' analysis indicates that through 2050, increases in annual light-duty fuel consumption and CO₂ emissions would remain below 10%, and increases in annual light-duty emissions of smog-forming pollutants would remain below 2.5%.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

As the analysis affirms, while fuel economy and CO₂ emissions are two sides (or, arguably, the same side) of the same coin, fuel economy and CO₂ are only incidentally related to pollutants such as smog, and any positive or negative impacts of today's rulemaking on these other air quality problems would most likely be far too small to observe.

The remainder of this section summarizes the impacts on fuel consumption and emissions for both the new final CAFE standards and the new final CO₂ standards.

(1) Understanding energy and environmental impacts

Today's rulemaking and accompanying FRIA and FEIS all examine a range of physical impacts. These impacts reflect the combined effect of a range of different factors, some of which are independent of one another, and some of which interact. The scope and nature of this set of factors is such that, even among knowledgeable experts, intuition is often uninformative or even misleading.

On one hand, it is reasonable to be confident that the more CAFE and CO₂ standards are relaxed, the more national-scale fuel consumption and CO₂ emissions will increase, because the standards apply directly to the average rates at which new vehicle consume fuel and, in turn, emit CO₂. While other factors—including some that work against this expectation—are involved, these other factors are insufficient to belie this basic expectation that less stringent standards will lead to increased fuel consumption and CO₂ emissions.

On the other hand, while it is intuitive to expect that the increased fuel consumption should lead to some additional emissions to produce and distribute fuel, those processes are expected to become cleaner over time, and refineries may respond by reducing exports of petroleum products rather than increasing overall activity. Although many believe that more fuel-efficient vehicles are, by definition, “cleaner”, most pollutants impacting air quality are regulated on an average per-mile basis, such that vehicles’ “cleanliness” is effectively independent from vehicles’ fuel economy.²³⁹¹ However, because emissions standards relevant to air quality are so much more stringent than in the past, and because some emission control technologies (e.g., catalytic converters) tend to deteriorate as vehicles age, average emission rates of vehicles are very dependent on when those vehicles were produced and how old they are. This means that total vehicular emissions of pollutants impacting air quality depend not directly on fuel economy, but rather on the amount of highway travel (since emissions are regulated on a per-mile basis) and on how that travel is distributed among older and newer vehicles. The agencies estimate that relaxing CAFE and CO₂ standards will, by decreasing the price and fuel economy levels of vehicles produced after MY 2017, lead to changes in the quantities of new vehicles produced and sold in the U.S., as well as changes in fleet mix (i.e., the relative shares of passenger cars and light trucks, which are subject to different emissions standards), and changes in the rates at which older vehicles are removed from service (i.e., scrapped). Is it reasonable to expect that less stringent standards will necessarily accelerate the turnover to newer, cleaner vehicles? Does that depend on fuel prices? Yet another factor involves the prevalence of electric vehicles, which emit no air pollutants directly, but do use electricity. How might that electricity be generated in the future? Also, does it necessarily follow that less stringent CAFE and CO₂ standards will reduce the sale of battery electric vehicles (BEVs) in the long term? Could less stringent standards increase long-term BEV sales if

²³⁹¹ For example, in 42 U.S.C. § 7521(g), the 1990 Clean Air Act Amendments defined specific numerical standards for passenger car and light truck CO, NMHC (i.e., VOC), and NOx emission rates, and defined them on a gram per mile basis, such that the 3-cylinder 1993 Geo Metro and the 12-cylinder 1993 Ferrari 512 were both regulated to 0.4 grams per mile of NOx, even though the Metro's average fuel economy rating, at 47 mpg, was more than four times greater than the Ferrari's 11 mpg rating.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturers are able to make early investments in BEV research and development, or wait for the costs of BEV systems to decline, rather than making larger nearer-term commitments to, say, very advanced engine technologies? With air quality depending on how emissions of various pollutants are impacted (and sometimes in different ways) by these factors, there is scant basis for *a priori* expectations regarding the direction, much less the magnitude of air quality impacts under the various regulatory alternatives.

Although, like any other model, the CAFE model involves many uncertainties and does not account for every possible factor or interaction, the model does enable the agencies to estimate emissions impacts accounting for the factors mentioned above, and specific results can be understood through careful examination of model inputs, outputs, and methods. To illustrate this, we consider estimated emissions of nitrogen oxides (NO_x), a class of pollutants that contribute to the formation of ground-level ozone (i.e., smog) that is harmful to public health and welfare. We apply the same “unconstrained” modeling approach as underlies the FEIS. Graphing estimated annual tailpipe, upstream, and combined total NO_x emissions from passenger cars and light trucks shows emissions declining significantly over time, with results from the various action alternatives (focusing here on the least stringent, preferred, and most stringent alternatives, and applying the same vertical scale to all three charts) being virtually indistinguishable from the no-action alternative:

Figure VII-3 - Annual Tailpipe NO_x Emissions

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure VII-4 - Annual Upstream NOx Emissions

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure VII-5 - Annual Total (Tailpipe and Upstream) NOx Emissions

Closer examination, though, reveals that although differences are very small on a relative scale, they do exhibit definitive trends. Reducing stringency causes total annual tailpipe NOx emissions to decline initially, as scrappage of older higher-emitting vehicles is accelerated and sales of new vehicles increase slightly relative to augural standards. Over time, both of these trends are impacted by steadily increasing fuel prices, but more important, reducing stringency causes the market to shift somewhat more slowly to electric vehicles than under the augural standards. Because electric vehicles emit no NOx directly, the impact on NOx emissions of this dampening of electric vehicle sales eventually outweighs the other impacts, such that by approximately 2035, less stringent standards begin increasing annual tailpipe NOx emissions rather than decreasing these emissions (relative to the augural standards):

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure VII-6 - Changes (Relative to Augural Standards) in Annual Tailpipe NOx Emissions

On the other hand, at least through 2050, less stringent standards show increased upstream NOx emissions. These increases continue to build through the late 2030s, as total fuel consumption under the less stringent standards continues to increase relative to levels under the augural standards. However, by 2040, these increases are steadily shrinking, due to the same delayed shift to electric vehicles:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure VII-7 - Changes (Relative to Aogural Standards) in Annual Upstream NOx Emissions

Model outputs indicate that on a per-mile basis, upstream NOx emissions beyond 2030 are 2-24 percent greater for electricity than for gasoline, varying over time and between regulatory alternatives. (Although the agencies have applied the same upstream emission factors to all regulatory alternatives, comparative per-mile upstream emissions also depend on comparative vehicle efficiency.) This means that, although a shift to electrification reduces tailpipe emissions, it also tends to increase net upstream emissions.

Taken together, these changes in tailpipe emissions produce very slight decreases in overall annual NOx emissions through about 2026 under each regulatory alternative. Beyond 2026, the regulatory action alternatives all produce increased overall annual NOx emissions relative to the aogural standards, although for the most stringent regulatory alternative considered here, these increases plateau after about 2040:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure VII-8 - Changes (Relative to Augural Standards) in Annual Total (Tailpipe and Upstream) NOx Emissions

Still, although trends and differences between regulatory alternatives are clear on the scale of the last three of the above charts, the preceding three charts place these emissions changes in context, and show that they are barely discernable. For example, the largest increase shown in the last of the above charts is about 0.015 million tons, in 2050, when total emissions are 0.33-0.35 million tons, down from about 1.5 million tons in 2017. In other words, the largest increase in overall annual NOx emissions is only about 1 percent of recent annual NOx emissions attributable to passenger cars and light trucks.

The FEIS accompanying today's rulemaking presents tailpipe, upstream, and total emissions for a range of pollutants, and presents results of photochemical modeling to estimate corresponding changes in air quality, as well as results of calculations to estimate resultant health impacts. As indicated by the following chart, at least for the final standards, VOC and PM emissions follow overall trends broadly similar to those followed by NOx emissions, although, relative to recent (2017) total emissions attributable to passenger cars and light trucks, changes in VOC and PM emissions are not as small as changes in NOx emissions. Under the final standards, combined tailpipe and upstream CO emissions are very slightly lower than under the augural standards through the early 2030s, after which these emissions changes begin increasing at rates similar to those for VOC, NOx, and PM. CO₂ emissions changes exhibit the expected trend mentioned above, with combined tailpipe and upstream emissions steadily increasing under the final standards. However, the final standards lead combined tailpipe and upstream SO₂ emissions to *decrease* relative to the augural standards, and as a share of 2017 emissions, these decreases grow from about 2 percent in 2035 to about 10 percent in 2050:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure VII-9 - Change under Final Standards (vs. Augural Standards), as Share of 2017 Total (Tailpipe + Upstream) Emissions

As indicated by the following chart, changes in tailpipe SO₂ emission follow trends nearly identical to those followed by changes in CO₂ emissions, because both result directly from the quantity and composition (sulfur and carbon per gallon, respectively) of fuel consumed:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure VII-10 - Change under Final Standards (vs. Augural Standards), as Share of 2017 Tailpipe Emissions

This means that the decreases in overall SO₂ emissions must be attributable to decreases in upstream SO₂ emissions. The following chart shows SO₂ emissions decreases becoming steadily larger after the mid-2030s, suggesting that, as discussed above, delaying the shift to electric vehicles leads to delays in emissions from electricity generation, and for some pollutants (notably below, SO₂ and CO₂), these emissions from electricity generation are large enough to reverse trends in overall emissions changes. For SO₂, this reflects, among other things, the fact that, in order to enable catalytic converters to operate more efficiently, gasoline in sulfur is now limited to an average of 10 parts per million.²³⁹²

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure VII-11 - Change under Final Standards (vs. Augural Standards), as Share of 2017 Upstream Emissions

Again, the FEIS accompanying today’s rulemaking further explores changes in emissions; the purpose of this discussion is not to duplicate material appearing in the FEIS, but rather to discuss some of the underlying factors and how they can lead to some of the trends reported in the FEIS.

Unlike the FEIS, today’s rulemaking and accompanying FRIA largely examine impacts on a “model year basis.” As discussed below, while a calendar year basis involves considering impacts in one or a series of calendar years, a model year basis involves considering impacts over the useful lives of vehicles produced in one or over a series of model years. A calendar year approach answers the question “what do we estimate will happen in, for example, 2035?,” and a model year approach answers the question “what impacts do we estimate will be attributable to vehicles produced in 2025?” The calendar approach does not extend beyond 2050, the last year in which the analysis includes a complete on-road fleet. On the other hand, while it accounts for model year 2050 vehicles’ fuel consumption and emissions through 2089, the model year approach as implemented here does not extend beyond model year 2029.

These are differences in temporal perspective that, for some types of impacts, lead to differences in reported trends. For example, returning to tailpipe NOx emissions, [Figure VII-6](#) (using the calendar year perspective) shows that relaxing the stringency of CAFE standards leads annual tailpipe NOx emissions to increase starting around 2035, but leads these emissions to *decrease* in the nearer term. As discussed above, this shift can be attributed to the less stringent standards leading to a delayed shift toward electric vehicles. Because the model year perspective as implemented here extends through 2029, it largely

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

sets aside this shift to electric vehicles, even for the “unconstrained” modeling underlying the FEIS (modeling which, unlike the “standard setting” type of analysis required by EPCA, considers that, even during 2018-2029, additional electric vehicles might be produced in response to standards). Consequently, unlike the calendar year perspective as applied beyond 2035, the model year perspective that extends through MY 2029 always shows tailpipe NOx emissions decreasing as the stringency of CAFE standards is relaxed relative to the augural standards.

In addition to this difference in temporal perspective, the FEIS, relative to the rulemaking and FRIA, applies a perspective that is different in terms of how manufacturers could respond to standards. The “unconstrained” modeling underlying the FEIS allows for the potential that manufacturers might apply CAFE compliance credits or introduce additional electric vehicles in any model year. This is intended to reflect how manufacturers might respond to standards in the real world. However, EPCA requires that, for purposes of determining the maximum feasible standards, NHTSA set aside the potential that manufacturers might apply credits or increase electric vehicle offerings in the model years under consideration. Therefore, for CAFE, the preamble and FRIA use modeling that sets aside the potential use of credits and the potential introduction of new electric vehicles through 2029 (although, since standards prior to MY 2021 are not subject to reconsideration, this modeling does consider the potential use of credits through MY 2020). As indicated by the following chart, especially prior to model year 2030, this leads to significant differences in EV market penetration between the two types of analyses:

Figure VII-12 – Estimated Electric Vehicle Share of New Vehicle Market

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Over time, these differences in EV sales lead to significant differences in the steadily accumulating share of overall highway travel powered with electricity:

Figure VII-13 – Estimated Share of Overall Annual VMT Powered with Electricity

For most pollutants, the fact that EVs do not emit air pollutants outweighs the fact that combustion-based power plants do. As discussed above, sulfur content in gasoline is so low that the opposite is the case for net SO₂ emissions.

A complete quantitative analysis of differences between calendar year-based emissions trends shown in the FEIS and model year-based emissions trends shown in the rulemaking and FRIA would involve examination of all of the factors mentioned above. However, considering the temporal difference in perspective between the two types of analyses, and considering the differences in the timing and pace of the estimated transition to electric vehicles, differences in emissions trends are inevitable.

(2) CO₂ damages

Section V discusses, among other things, the need of the Nation to conserve energy, providing context for the estimated impacts on national-scale fuel consumption summarized below. Corresponding to these changes in fuel consumption, the agencies estimate that today's final rule will impact CO₂ emissions. CO₂ is one of several gases that absorb infrared radiation, thereby trapping heat and potentially making the planet warmer. The most important such gases directly emitted by human activities include carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), and several fluorine-containing halogenated substances.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Although CO₂, CH₄, and N₂O occur naturally in the atmosphere, human activities have changed their atmospheric concentrations. From the pre-industrial era (i.e., ending about 1750) to 2016, concentrations of these gases have increased globally by 44, 163, and 22%, respectively.²³⁹³ The FEIS accompanying today's rulemaking discusses the potential impacts of the emission of such gases at greater length, and also summaries analysis quantifying some of these impacts (e.g., average temperatures) for each of the considered regulatory alternatives.

(3) Other pollutant damages – criteria and toxic pollutants

The CAFE model uses the entire on-road fleet, calculated VMT (discussed above), and emissions factors (which are an input to the CAFE model, specified by model year and age) to calculate tailpipe emissions associated with a given alternative. Just as it does for additional CO₂ emissions associated with upstream emissions from fuel production, the model captures criteria pollutants that occur during other parts of the fuel life cycle. While this is typically a function of the number of gallons of gasoline consumed (and miles driven, for tailpipe criteria pollutant emissions), the CAFE model also estimates electricity consumption and the associated upstream emissions (resource extraction and generation, based on U.S. grid mix).

(a) Emissions increases

(b) *Air quality impacts of other pollutants*

Although this final rule focuses on standards for fuel economy and CO₂, it will also have an impact on criteria and air toxic pollutant emissions, although as discussed above, it is expected that incremental impacts on criteria and air toxic pollutant emissions would be too small to observe under any of the regulatory alternatives under consideration. Nevertheless, the following sections detail the criteria pollutant and air toxic inventory impacts of this final rule; the methodology used to calculate those impacts; the health and environmental effects associated with the criteria and toxic air pollutants that are being impacted by this final rule; the potential impact of this final rule on concentrations of criteria and air toxic pollutants in the ambient air; and other unquantified health and environmental effects.

Today's analysis reflects the combined result of several underlying impacts, all discussed above. CAFE and CO₂ standards are estimated to impact new vehicle prices, fuel economy levels, and CO₂ emission rates. These changes are estimated to impact the size and composition of the new vehicle fleet and to impact the retention of older vehicles (i.e., vehicle survival and scrappage) that tend to have higher criteria and toxic pollutant emission rates. Along with the rebound effect, these lead to changes in the overall amount of highway travel and the distribution among different vehicles in the on-road fleet. Vehicular emissions depend on the overall amount of highway travel and the distribution of that travel among different vehicles, and emissions from "upstream" processes (e.g., petroleum refining, electricity generation) depend on the total consumption of different types of fuels for light-duty vehicles.

(i) Impacts

As discussed above, in addition to affecting fuel consumption and emissions of carbon dioxide or its equivalent, this rule would also influence other pollutants, i.e., "criteria" air pollutants and their precursors, and air toxics. The final rule would affect emissions of carbon monoxide (CO), fine particulate matter (PM_{2.5}), sulfur dioxide (SO_x), volatile organic compounds (VOC), nitrogen oxides (NO_x), benzene, 1,3-butadiene, formaldehyde, acetaldehyde, and acrolein. Consistent with the evaluation conducted for the Environmental Impact Statement accompanying today's rule, the agency analyzed criteria air pollutant impacts in 2025, 2035, and 2050 (as a representation of future program impacts). Estimates of these other emission impacts are shown by pollutant in [Table VII-124](#) through [Table VII-127](#) and are broken down by the two drivers of these changes: a) "downstream" emission changes, reflecting the estimated effects of VMT rebound (discussed in Section VIII of the FRIA), changes in vehicle fleet age, changes in vehicle emission standards, and changes in fuel consumption; and b) "upstream" emission increases because of increased refining and distribution of motor vehicle gasoline relative to the baseline. Program impacts on criteria and toxics emissions are discussed below.

As discussed above, these changes in total annual criteria pollutant emissions attributable to passenger cars and light trucks reflect trends in both vehicular and upstream emissions, and these trends can either be mutually reinforcing or mutually offsetting, depending on the pollutant and year. Above, [Figure VII-9](#) places these total changes in emissions in context, showing that, except for SO₂, these changes in criteria pollutant emissions are very small. For SO₂ emissions, changes are also very small through the late 2030s, after which reduced upstream emissions cause net emission reductions to exceed 10 percent of 2017 emissions by 2050.

As shown in ~~Table VII-128~~Table VII-128 through

~~Table VII-131~~Table VII-131, it is estimated that the new final program would result in small changes for air toxic emissions compared to total U.S. inventories across all sectors. These changes also reflect the changing balance between vehicular and upstream emissions.

Changes in emissions of other pollutants due to these rules will impact air quality. Information on current air quality and the results of our air quality modeling of the projected impacts of these rules are summarized in the following section.

(ii) Other Unquantified Health and Environmental Effects

In the proposal, the agencies sought comment on whether there are any other health and environmental impacts associated with advancements in technologies that should be considered. For example, the use of technologies and other strategies to reduce fuel consumption and/or CO₂ emissions could have effects on a vehicle's life-cycle impacts (e.g., materials usage, manufacturing, end of life disposal), beyond the issues regarding fuel production and distribution (upstream) CO₂ emissions discussed in Section VI.D.2. The agencies sought comment on any studies or research in this area that should be considered in the future to assess a fuller range of health and environmental impacts from the light-duty vehicle fleet shifting to different technologies and/or materials. At this point, the agencies find there is insufficient information about the lifecycle impacts of the myriad of available technologies, materials, and cradle-to-grave pathways to conduct the type of detailed assessments that would be needed in a regulatory context, especially considering the characterization of specific vehicles in the analysis fleet and the characterization of specific technology options.

(c) *Health effects of other pollutants*

This section discusses health effects associated with exposure to some of the criteria and air toxic pollutants impacted by the new final vehicle standards.

B. Impacts on calendar year basis

As with the NPRM, the agencies' analysis primarily examines regulatory impacts on a model year basis, accounting for the physical impacts and monetized costs and benefits attributable to vehicles produced prior to model year 2030 and occurring throughout these vehicles' useful lives. EDF submitted comments arguing that the agencies should examine impacts on a calendar year basis, as discussed above in VI.A.²³⁹⁴ CAFE analysis has historically examined effects of the standards on a model year basis, because CAFE (and CO₂) standards are enforced on a model year basis, and manufacturers' responses to these standards (i.e., their costs), which are the direct effects of the standards, occur on a model year basis. On the other hand, overall impacts on national energy consumption and the environment result from the evolution and operation of the overall on-road fleet, and this motivates consideration of results on a calendar year basis. As also discussed in VI.A., the agencies have expanded the presentation of results in today's rulemaking and FRIA by presenting some impacts for each of CYs 2017-2050 and, to enable doing so, have extended the analysis to cover model years through 2050.

For this analysis, the CAFE model reports impacts for each model year through 2050, and, to capture the entire useful lives of these vehicles, for each of calendar years 2017-2089.²³⁹⁵ One way to illustrate the model's outputs is to consider three cohorts of model years: MYs 1978-2017 (MYs to which the analysis applies no additional fuel-saving technology), MYs 2018-2029 (MYs included in both the "MY basis" and "CY basis" approaches), and MYs 2030-2050 (MYs included only the "CY basis" approach). On a calendar year basis, impacts of the final standards on annual CO₂ emissions (impacts on fuel consumption would follow essentially the same trends) may be attributed to these cohorts as follows:

²³⁹⁴ EDF, NHTSA-2018-0067-12108, Appendix A at 9, *et seq.*, and Appendix B at 11-14.

²³⁹⁵ As for the NPRM, DOT has made the model and all inputs and outputs for today's analysis available at <https://www.nhtsa.gov/corporate-average-fuel-economy/compliance-and-effects-modeling-system>. The model documentation available at the same location explains, among other things, the structure and contents of each type of input and output file. The "annual_societal_effects_report.csv" and "annual_societal_costs_report.csv" reports contain, respectively, estimates of physical impacts and monetized costs and benefits attributable to each model year in each calendar years. Other output file types contain corresponding aggregations either all calendar years, or across all model years.

Figure VII-14 – Estimated CO₂ Emissions (mmt) from MYs 1978-2050 Passenger Cars and Light Trucks

Here, the large lower area of the chart shows annual CO₂ emissions estimated to occur under the baseline/augural CAFE standards, through calendar year 2089, which is the last year any MY 2050 vehicles are estimated still to be on the road. The steady declines through 2050 reflect turnover to more efficient vehicles produced under either regulatory alternative, and the steep decline after 2050 reflects vehicles included in the analysis being removed from service. Of the increased annual emissions under the final standards, the black area shows the portion attributable to vehicles produced during MYs 2018-2029, and the topmost area shows the portion attributable to vehicles produced during MYs 2030-2050. The final standards are estimated to reduce emissions from vehicles produced during MYs 1978-2017 by accelerating scrappage of these vehicles, but these changes are too small to be visible in this chart.

The bulk of the reporting of results here and in the FRIA examines impacts over the useful lives of vehicles produced prior to MY 2030. In terms of the above chart, this means excluding the topmost area, producing the following:

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Figure VII-15 – Estimated CO₂ Emissions (mmt) from MYs 1978-2029 Passenger Cars and Light Trucks

On the other hand, calendar year accounting, as considered for this analysis, includes all model years included in the analysis (i.e., through MY 2050), and examines impacts in all calendar years for which a full on-road fleet is simulated. In terms of the first of the above charts, this means “cutting off” results at calendar year 2050:

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Figure VII-16 – Estimated CO₂ Emissions (mmt) from Passenger Cars and Light Trucks through CY 2050

Here, the horizontal axis extends through 2089 to make clear that this calendar year accounting involves excluding emissions impacts over most of the useful lives of the latest model years included in the analysis. On a scale covering just those calendar years included in the calendar year analysis, the same chart appears as follows:

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Figure VII-17 – Estimated CO₂ Emissions (mmt) from Passenger Cars and Light Trucks through CY 2050

Viewed on the same calendar year basis, technology costs appear as follows, with differences between costs under the baseline/augural standards and under the final standards shown as amounts by which the former exceed the latter (e.g., in 2025, the final standards are estimated to avoid about \$19 billion in technology costs that would have been incurred under the baseline/augural standards):

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Figure VII-18 – Undiscounted Technology Costs (\$B) during CYs 2017-2050

Present value analysis considered involves discounting all estimated future costs and benefits to 2019. At a 7 percent discount rate, the undiscounted technology costs shown above correspond to discounted costs shown in the following chart:

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Figure VII-19 – Discounted (at 7%) Technology Costs (\$b) during CYs 2017-2050

Without discounting, therefore, the final standards avoid \$457 billion in technology costs through 2050, each additional year of analysis after 2036 adding about \$14 billion to that total. At a 7 percent discount rate, the final standards still avoid \$183 billion in technology costs, while incremental amounts attributable to each additional year of analysis are (of course) lower than the undiscounted amounts—declining to about \$5 billion during 2035-2036 and, by 2045, about \$2 billion.

For each of the regulatory alternatives considered here, the following tables summarize results of such aggregations for each reported category of monetized costs and benefits. The first three tables focus on the final CAFE standards, presenting total amounts through 2050 at 3 percent and 7 percent discount rates. The second three tables show results for corresponding CO₂ standards.

Net Benefits	(6)	(5)	1	3	5	8	8

As illustrated above, the model year analysis answers the question “what impacts do we think might eventually be attributable to vehicles produced before 2030?”, and the calendar year

analysis answers the question “what do we think might happen between now and 2050?” Again, CAFE and CO₂ standards are enforced on a model year basis, and the agencies accordingly simulate manufacturers’ responses to these standards—and estimate manufacturers’ corresponding costs—on a model year basis. This motivates consideration of results on a model year basis. On the other hand, overall impacts on national energy consumption and the environment result from the evolution and operation of the overall on-road fleet, and this motivates consideration of results on a calendar year basis.

These different perspectives produce results that, without careful consideration, appear to conflict. The model year perspective as applied through MY 2029 shows less stringent standards producing environmental *benefits* (compared to the augural standards) attributable to the aggregate of vehicles produced prior to MY 2030. While the calendar year perspective also shows similar trends prior to (calendar year) 2035, with the estimated transition to electric vehicles accelerating over time, the calendar year perspective shows less stringent standards mostly increasing emissions (SO₂ being an exception) relative to the augural standards.

Still, some important aspects of estimated social benefits and costs are common to both the model year and calendar year perspectives. For each of the regulatory action alternatives, the magnitude of total incremental benefits (relative to the baseline augural standards) is similar to the magnitude of total incremental costs. This stands in marked contrast to the agencies’ 2012 rulemaking announcing the augural standards, and finding of estimated benefits that were 3–4 times larger than costs.²³⁹⁶ Under today’s analysis, estimated benefits and costs are instead of similar magnitude, with estimated *net* benefits, by comparison, small enough to be even directionally uncertain, such that an alternative estimated to produce small positive net benefits under one perspective and applying a 7 percent discount rate might be estimated to produce small negative net benefits under the other perspective and/or applying a 3 percent discount rate. While the agencies obviously must consider benefits, costs, and net benefits, our decisions are based on wider considerations. Consistent with the agencies’ 2012 final rule, today’s final rule finds—from both the model year and calendar year perspectives—that forgone fuel savings (forgone because today’s final rule involves relaxing rather than increasing the stringency of CAFE and CO₂ standards) account for the bulk of estimated forgone social benefits. These are private benefits, which raises a significant question of whether there is a meaningful market failure that needs to be addressed by more stringent regulation.

Section VI contains an extensive discussion and analysis of the existence and nature of various market failures related to fuel economy standards. These potential market failures include the well-established externalities of environmentally harmful emissions, congestion, and safety; as well the debatable and hypothetical market failures related to the “energy paradox.” The energy paradox refers to an observation that some consumers appear voluntarily to forgo investments in energy conservation even when those initial investments appear to repay themselves – in the form of savings in energy costs – over the relatively near term. Section

²³⁹⁶ 77 FR at 62629 (Oct. 15, 2012).

VI.D.1 discussion casts doubt on the theoretical underpinnings that the energy paradox represents a market failure, discusses recent research that suggests the extent consumers are undervaluing fuel economy has been overstated, and suggests the analysis supporting claims of an energy paradox overlooks the opportunity costs of other vehicle attributes that consumers and manufacturers trade off with fuel efficiency technology. As stated in Section VI, while the agencies have reservations about the extent to which a market failure capable of driving very large net private financial harm to consumers exists, the agencies do not take a position on the existence of an energy paradox in this rulemaking.

The primary analysis shows that the CAFE final rule would generate \$12.9 billion in total social net benefits using a 7 percent discount rate, but without the large net private loss of \$26.4 billion, the net social benefits would equal the external net benefits, or \$39.3 billion. Therefore, given significant questions about whether government action to impose restrictions in private markets could improve net social benefits absent a market failure, if no market failure exists to motivate the \$26.4 billion in private losses to consumers, the net benefits of these final standards would be \$39.3 billion. The CY analysis produces similar results, though the estimated private losses are exacerbated relative to the external gains. The CY analysis shows the CAFE final rule would generate -\$6 billion in total net social benefits using a 7 percent discount rate, but without the large net private loss of \$65 billion, the net social benefits would equal the external net benefits of \$59 billion.

One commenter suggested we should elect to use CY accounting in the primary analysis because the MY accounting approach resulted in an inconsistent accounting of costs and benefits owing to the scrappage effect. While the CY accounting approach does reduce non-rebound safety benefits from \$9 billion to \$8 billion (combined fatal and non-fatal benefits), the total external net benefits of the rule actually increase by \$20 billion using the CY approach. This result is driven primarily by a significant increase in congestion cost savings from less rebound driving, from \$44 billion to \$69 billion. Any changes in the net benefits in the opposite direction using CY accounting result from increased net private costs to consumers own financial wellbeing from allowing more consumer choice. These increased net private costs occur because the CY analysis captures model years far into the future, which are more uncertain and not subject to today's CAFE final rule. Therefore, we see little evidence that the inconsistency suggested by the commenter is important, or that the primary conclusions of the analysis are meaningfully influenced by it.

C. Sensitivity analysis

As discussed at the beginning of this section, results presented today reflect the agencies' best judgments regarding many different factors. Based on analyses in past rulemakings, the agencies recognize that some analytical inputs are especially uncertain, some are likely to exert considerable influence over specific types of estimated impacts, and some are likely to do so for the bulk of the analysis. To explore the sensitivity of estimated impacts to changes in model inputs, analysis was conducted using alternative values for a range of different inputs. Results of this sensitivity analysis are summarized in the Final Regulatory Impact Analysis (FRIA)

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

accompanying today's rulemaking, and detailed model inputs and outputs are available on NHTSA's web site.²³⁹⁷ The following table lists the cases included in the sensitivity analysis.

Table VII-148 – Cases Included in Sensitivity Analysis

Sensitivity Case	Description
Reference Case	Reference case
Implicit Value Loss	Consumer value loss offsetting fuel savings beyond payback period
Consumer Benefit at 50%	Assume 50% loss in consumer surplus – equivalent to the assumption that consumers will only value the calculated benefits they receive at 50 percent of the analysis estimates
Consumer Benefit at 75%	75% loss in consumer surplus
12 Month Payback Period	12-month payback period (i.e., voluntary application of technologies paying back within first year of vehicle ownership)
24 Month Payback Period	24-month payback period
36 Month Payback Period	36-month payback period
High Oil Price	High fuel price estimates
High Oil Price with 60 Month Payback Period	High fuel price estimates and a 60-mo. payback period
Low Oil Price	Low fuel price estimates
Low Oil Price with 12 Month Payback Period	Low fuel price estimates and a 12-mo. payback period
High GDP	High economic growth, AEO2019
Low GDP	Low economic growth, AEO2019
High Social Cost of Carbon	High social cost of carbon
Low Social Cost of Carbon	Low social cost of carbon
Global Social Cost of Carbon with 3% Discount Rate	Global Social Cost of Carbon with 3% Discount Rate
Global Social Cost of Carbon with 7% Discount Rate	Global Social Cost of Carbon with 7% Discount Rate
Nonzero Valuation of CH ₄ and N ₂ O	CH ₄ and N ₂ O valued at \$209 and \$2491 per ton, respectively.
No Impact on Domestic Refining	US refining share – US consumption changes have no impact on domestic refining
Maximum Impact on Domestic Refining	US refining share – All changes in US consumption are refined domestically

²³⁹⁷ The CAFE model and all inputs and outputs supporting today's rulemaking are available at <https://www.nhtsa.gov/corporate-average-fuel-economy/compliance-and-effects-modeling-system>.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Sensitivity Case	Description
Scrappage, Sales, and Fleet Share Models Disabled	Keeps average new vehicle prices at MY2016 levels within the scrappage model throughout the model simulation; this disables the effect of slower scrappage when new vehicle prices increase across more stringent scenarios.
Elasticity of Scrappage to New Vehicles Varies with Age	Price effect varies with age. This model exists already.
High Sales and Scrappage Response to New Vehicle Prices	Price elasticity of -1.25, scrappage model at 95% CI values
Low Sales and Scrappage Response to New Vehicle Prices	Price elasticity of -0.75, scrappage model at 5% CI values
Rebound Effect at 10%	Rebound effect, the increase miles traveled as the cost of travel decreases, is set to 10%
Rebound Effect at 30%	Rebound effect set to 30%
On Road Gap 0.30	On-road gap is set to 30%
Safety Coefficient at 5th Percentile	Lower bounds of confidence interval of safety coefficients
Safety Coefficient at 95th Percentile	Upper bounds of confidence interval of safety coefficients
Low Crash Avoidance Technology Effectiveness	Lower range effectiveness estimates for all 6 crash avoidance technologies
High Crash Avoidance Technology Effectiveness	Higher range effectiveness estimates for all 6 crash avoidance technologies
Technology Cost Markup 1.10	Technology retail price equivalent (RPE) of 1.10 (i.e., 10% markup of direct costs)
Technology Cost Markup 1.24	Technology retail price equivalent (RPE) of 1.24 (i.e., 24% markup of direct costs)
Technology Cost Markup 2.00	Technology retail price equivalent (RPE) of 2.00 (i.e., 100% markup of direct costs)
Higher Battery Direct Costs and Reference Case Learning	15% higher direct manufacturing cost (DMC)
Lower Battery Direct Costs and Reference Case Learning	10% lower DMC
Reference Case Battery Direct Costs and Faster Learning	learning 6.0% early
Higher Battery Direct Costs and Faster Learning	15% higher DMC and learning 6.0% early
Lower Battery Direct Costs and Faster Learning	10% lower DMC and learning 6.0% early
Reference Case Battery Direct Costs and Slower Learning	learning 3.5% early
Higher Battery Direct Costs and Slower Learning	15% higher DMC and learning 3.5% early
Lower Battery Direct Costs and Slower Learning	10% lower DMC and learning 3.5% early
Unconstrained BEV adoption	No caps on BEV adoption

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Sensitivity Case	Description
Slower BEV adoption	Tighter caps on BEV300 penetration
Exclude Strong Hybrids	Additional strong hybrids are excluded from the analysis
HCR0 and HCR1 Available Except in Pickups	HCR0 and HCR1 is included in the analysis for all non-pickup vehicles.
HCR2 Available	HCR2 engine applicable for all OEMs and technology classes
VCR Available for All Vehicles	VCR engine applicable for all OEMs and technology classes
Skip Peripheral Technologies	Disable LDB, SAX, EFR, ROLL20, AERO20, DSLI
Low Initial Road Load Reduction	Set initial level of body-level technologies to zero (ROLL0, AERO0, MR0)
Long Fleet Redesign Cadence	Redesign cadence (schedule of major technology upgrades for vehicles, engines, etc.) is extended to 1.2 times that of the reference case (rounded to nearest MY)
Short Fleet Redesign Cadence	Redesign cadence shortened to a 0.8 times that of the reference case (rounded to nearest MY)
1-Year Redesign Cadence	Vehicles redesigned every year
NPRM effective cost metric	Run NPRM version now that central version uses cost/credit
NPRM effective cost metric w/High Oil Price	NPRM version with high fuel price estimates
NPRM effective cost metric w/Low Oil Price	NPRM version with low fuel price estimates
Fewer Off-Cycle Credits	Max at 7 g/mi
More Off-Cycle Credits	Max at 15 g/mi
No Credit Carry-Forward	Disables credit carry-forward
Allow CAFE Fine Payment with \$5.00 Civil Penalty	Treats all manufacturers as willing to pay fines, with \$5.00 civil penalty rate
Allow CAFE Fine Payment with \$5.50 Civil Penalty	Treats all manufacturers as willing to pay fines, with \$5.50 civil penalty rate
Allow CAFE Fine Payment with \$14.00 Civil Penalty	Treats all manufacturers as willing to pay fines, with \$14.00 civil penalty rate
Maximum technology scenario	Apply technology at fastest possible rate (very high stringency)
No CAFE/ CO ₂ standards	
Perfect Trading of CO ₂ Credit Trading	Entire fleet treated as being produced by a single manufacturer. CO ₂ program only.
No AC Leakage Credits	Add alternative with final standards that would apply without AC credits. CO ₂ program only.

VIII. How do the final standards fulfill the agencies' statutory obligations?

A. How does the technical assessment support the final CO₂ standards as compared to the alternatives that EPA has considered?

1. Introduction

Beginning in 2009, EPA and NHTSA have worked together jointly to establish fuel economy and tailpipe CO₂ emission standards for light duty vehicles. The first rulemaking, finalized in 2010, established standards for the 2012 through 2016 model years. Shortly thereafter, in 2012, the agencies established standards for the 2017 through 2025 model years—but given the limitation in EPCA that only allows for standards to be set five years at a time, the 2022-2025 model year standards were only final for EPA's tailpipe CO₂ emissions regulation. This rapid period of rulemaking to establish standards over a decade in advance may have marked a departure for NHTSA, but it followed EPA's longstanding approach when regulating vehicular criteria pollutant emissions to provide a significant period of time for the industry to develop technologies to achieve standards.

While EPA had decades of experience regulating light duty vehicle emissions, it did not previously have experience regulating tailpipe CO₂ emissions. And regulating CO₂ emissions is quite different from regulating criteria pollutant emissions. With criteria pollutants, technological emission controls exist primarily in the form of engine controls and catalytic conversion. Today's²³⁹⁸ emission controls for criteria pollutants have only a de minimis effect on performance or functionality of the vehicle.²³⁹⁹ Given the lack of performance impact for criteria pollutant emission controls, long lead times make sense, because automakers can design emission control technologies in a manner to minimize any adverse effect on performance or utility.

Controlling tailpipe CO₂ emissions for an internal combustion engine, in contrast, requires controlling the amount of energy used to propel the vehicle. All else being equal, better performance (in acceleration or passing speed) requires more energy. Similarly, vehicles with more storage capacity tend to be larger, and moving an object with larger mass requires more energy than objects with smaller mass. Vehicles with greater towing performance likewise require more energy. Maintaining utility and performance requires sophisticated and expensive technological solutions, such as reducing mass through advanced materials, changing engine combustion cycles, increasing compression ratios, or turbo-charging the engine. And unlike with controls for criteria pollutants, consumers can feel the difference in vehicle performance.

²³⁹⁸ EPA's first criteria pollutant standards in the 1970s and early 1980s did impact vehicle performance and driveability. However, subsequent standards required more precise fuel delivery systems and feedback control systems to achieve high catalytic converter efficiencies.

²³⁹⁹ While diesel emission controls have a larger effect on vehicle performance, diesels make up only a very small portion of the light-duty vehicle fleet.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Accordingly, EPA believes that consumer demand is an important consideration in setting CO₂ emission standards, because one of EPA's goals in setting the standards has been and continues to be to allow manufacturers to provide, and consumers to purchase, vehicles with varying attributes and functionality rather than to shift demand to certain vehicle types or sizes. Societal and economic trends play a role in this area as well—if fuel prices are relatively high, demand for fuel-efficient vehicles increase and, as a result, compliance with standards is easier to achieve. If fuel prices are relatively low—as they are now and are projected to be in the mid-term—consumer demand for fuel-efficiency is less strong, making it harder for manufacturers to comply with the standard. While manufacturer difficulty in complying due to lack of consumer demand may not be the deciding factor in determining the appropriate levels of stringency for standards, it is relevant to understanding lead time difficulties, which EPA is required to consider under Section 202(a)(2).

As discussed when issuing the 2012 Final Rule, the economic and market assumptions underlying the standards the agencies finalized were crucial, and long-term projections are inherently uncertain. Upon review of those assumptions, the agencies have now concluded that many of these assumptions have not proven to be accurate and therefore have been updated. Given the uncertainty about the 2012 assumptions at the time of that rulemaking, the agencies incorporated a mid-term evaluation process for EPA's 2022-2025 model year standards that would be "collaborative, robust and transparent," and "based on information available at the time of the mid-term evaluation and an updated assessment of all the factors considered in setting the standards and the impacts of those factors on the manufacturers' ability to comply."²⁴⁰⁰

While that process was expected to take place throughout 2017, and a final determination issued in the Spring of 2018, this process was expedited. On July 27, 2016, the agencies published a federal register notice making the public aware of the availability of a draft Technical Assessment Report, with comments due at the end of September 2016. On December 6, 2016, EPA published a notice in the federal register making the public aware of its proposed Final Determination and extensive Technical Support Document to keep the standards set in 2012 in place through the 2025 model year without change. The public was given until December 30, 2016 to comment on the proposed determination. Less than two weeks later, on January 12, 2017, EPA finalized its determination.

Industry commenters stated that the 2017 Final Determination "is the product of egregious procedural and substantive defects and EPA should withdraw it," that EPA had "fail[ed] to provide an adequate period for meaningful notice and comment," that EPA had "acknowledg[ed] that the Proposed Determination adjusted a number of EPA assumptions in response to commenters who pointed out errors at earlier stages" while stating that "there was no need for more time because [it] did not include much new material," and that "EPA [had] underestimated the burden [of the standards]," "EPA [made] cursory assertions that downplayed

²⁴⁰⁰ 77 FR at 62633.

the impact of its mandate on auto sales and employment,” and “EPA refused to consider many of the [industry’s] technical concerns even when supported by an outside consultant, asserted [industry] provided insufficient data, and then refused further meetings for clarification.”²⁴⁰¹

In March 2017, EPA announced its intent to reconsider the final determination in order to allow additional opportunity to hear from the public, and additional consultation and coordination with NHTSA in support of a national harmonized program. In August 2017, EPA published a notice in the Federal Register requesting comment on its reconsideration of the initial determination, and held a public hearing on the matter in September 2017. Then, in April 2018, EPA issued a revised final determination finding that the 2022-2025 model year GHG standards set in 2012 were not appropriate and a rulemaking should be initiated to revise the standards, as appropriate.

In this proceeding, in order to determine what standards are appropriate, EPA and NHTSA sought comment on a wide range of potential standards—ranging from holding the 2020 standards flat through the 2026 model year to retaining the standards finalized in 2012. Similar to the 2012 rulemaking, EPA considered a number of different alternatives—ranging from the standards finalized in 2012, to holding the 2020 MY standards flat through MY 2026. As in 2012, the manner in which different factors are weighed can yield very different result—more stringent standards would improve CO₂ emissions, reduce energy consumption, and save consumers fuel. Less stringent standards would reduce technology costs for manufacturers and save consumers in upfront purchase prices, enabling the fleet to turnover more quickly. While weighing these factors, EPA has considered compliance results that have been observed throughout the fleet. While the agencies have seen extraordinary reductions in tailpipe CO₂ emissions since EPA has begun regulation in this area, manufacturers are increasingly falling short of meeting their performance targets, and are increasingly using acquired or earned credits to comply with requirements. For the 2016 model year, the overall fleet failed, for the first time in regulation history, to meet performance targets—achieving 272 grams per mile, when the standard was 263 grams per mile.²⁴⁰² The 2016 model year saw only five major manufacturers achieve their CO₂ footprint standards—Honda, Hyundai, Mazda, Nissan, and Subaru. For the 2017 model year, only three major manufacturers—BMW, Honda, and Subaru—performed better than their CO₂ standards, and the total fleet underperformed compared to the standards—achieving 263 grams per mile, when the fleetwide standard was 258 grams per mile.²⁴⁰³ The credit system was established to allow manufacturers greater flexibility and lead time to address technical feasibility and cost without sacrificing effectiveness of the standards, but widespread reliance upon credits across the industry may raise concerns about compliance in future years, particularly since the more significant increases in stringency in the 2012 rulemaking have yet to

²⁴⁰¹ Alliance letter to Administrator Pruitt, Feb. 21, 2017, available at <https://autoalliance.org/wp-content/uploads/2017/02/Letter-to-EPA-Admin.-Pruitt-Feb.-21-2016-Signed.pdf>.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

be effective. Taken together, the agencies now believe this information supports the conclusion that the lead time EPA estimated would be sufficient to achieve compliance with the previous standards for MYs 2021-26, was not sufficient.

In this action, EPA is reducing the rate of stringency increases from those adopted in the 2012 rulemaking in part to ensure that the standards remain reasonable and appropriate. As in 2012, EPA is deciding against selecting alternatives that are more stringent or less stringent than appropriate. The final rule analysis projects that the 1.5 percent alternative would result in less significant shortfalls compared to more stringent alternatives, which will ease compliance burdens while nonetheless pushing the market beyond what it would demand in the absence of standards or what would be achieved with less stringent standards. The standards finalized today will result in continuing improvements compared to the 2020 model year, and are best viewed in the context of the larger rulemaking, as shown in the chart below:

Figure VIII-1 Industry Average CO₂ Standards and Compliance MYs 2012-2026

2. Basis for the CO₂ standards under section 202(a) of the Clean Air Act

Title II of the Clean Air Act (CAA) provides for comprehensive regulation of mobile sources, authorizing EPA to regulate emissions of air pollutants from all mobile source categories. This rule implements a specific provision from Title II, section 202(a).²⁴⁰⁴ Section 202(a)(1) states that “[t]he Administrator shall by regulation prescribe (and from time to time revise) ... standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.” If EPA makes the appropriate endangerment and cause or contribute findings, then section 202(a) directs EPA to issue standards applicable to emissions of those pollutants.

Any standards under CAA section 202(a)(1) “shall be applicable to such vehicles and engines for their useful life.” Emission standards set by the EPA under section 202(a)(1) are technology-based, as the levels chosen must be premised on a finding of technological feasibility. Thus, standards promulgated under section 202(a) are to take effect only after “such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.”²⁴⁰⁵ EPA must consider costs to those entities which are directly subject to the standards.²⁴⁰⁶ Thus, “the [s]ection 202(a)(2) reference to compliance costs encompasses only the cost to the motor-vehicle industry to come into compliance with the new emission standards.”²⁴⁰⁷ EPA is afforded considerable discretion under section 202(a) when assessing issues of technical feasibility and availability of lead time to implement new technology. Such determinations are “subject to the restraints of reasonableness,” which “does not open the door to ‘crystal ball’ inquiry.”²⁴⁰⁸ In developing such technology-based standards, EPA has the discretion to consider different standards for appropriate groupings of vehicles (“class or classes of new motor vehicles”), or a single standard for a larger grouping of motor vehicles.²⁴⁰⁹

Although standards under CAA section 202(a)(1) are technology-based, they are not based exclusively on technological capability. EPA has the discretion, and in some instances has been specifically directed by Congress, to consider and weigh various factors along with technological feasibility, such as the cost of compliance²⁴¹⁰, lead time necessary for

²⁴⁰⁴ 42 U.S.C. 7521(a).

²⁴¹⁰ *See* section 202(a)(2).

compliance²⁴¹¹, safety,²⁴¹² other impacts on consumers,²⁴¹³ and energy impacts associated with use of the technology.²⁴¹⁴

Unlike standards set under provisions such as section 202(a)(3) and section 213(a)(3), EPA is not required to set technology-forcing standards when such standards would not be appropriate. EPA has interpreted a similar statutory provision, CAA section 231, as follows:

While the statutory language of section 231 is not identical to other provisions in title II of the CAA that direct EPA to establish technology-based standards for various types of engines, EPA interprets its authority under section 231 to be somewhat similar to those provisions that require us to identify a reasonable balance of specified emissions reduction, cost, safety, noise, and other factors. *See, e.g., Husqvarna AB v. EPA*, 254 F.3d 195 (D.C. Cir. 2001) (upholding EPA's promulgation of technology-based standards for small non-road engines under section 213(a)(3) of the CAA). However, EPA is not compelled under section 231 to obtain the "greatest degree of emission reduction achievable" as per sections 213 and 202 of the CAA, and so EPA does not interpret the Act as requiring the agency to give subordinate status to factors such as cost, safety, and noise in determining what standards are reasonable for aircraft engines. Rather, EPA has greater flexibility under section 231 in determining what standard is most reasonable for aircraft engines, and is not required to achieve a "technology forcing" result.²⁴¹⁵

This interpretation was upheld as reasonable in *NACAA v. EPA*.²⁴¹⁶ CAA section 202(a), as with section 231, does not specify the degree of weight to apply to each factor, and EPA accordingly interprets its authority under section 202(a) similarly to its interpretation of section 231 as set forth above: EPA has discretion in choosing an appropriate balance among the statutory factors.²⁴¹⁷

²⁴¹¹ *Id.*

²⁴¹² *See* NRDC, 655 F.2d at 336 n. 31.

²⁴¹³ Since its earliest Title II regulations, EPA has considered the safety of pollution control technologies. *See* 45 FR 14496, 14503 (March 5, 1980). ("EPA would not require a particulate control technology that was known to involve serious safety problems. If during the development of the trap-oxidizer safety problems are discovered, EPA would reconsider the control requirements implemented by this rulemaking.").

²⁴¹⁴ *See* *George E. Warren Corp. v. EPA*, 159 F.3d 616, 623-624 (D.C. Cir. 1998) (ordinarily permissible for EPA to consider factors not specifically enumerated in the CAA).

²⁴¹⁷ *See* *Sierra Club v. EPA*, 325 F.3d 374, 378 (D.C. Cir. 2003) (even where a provision is technology-forcing, the provision "does not resolve how the Administrator should weigh all [the statutory] factors in the process of finding the 'greatest emission reduction achievable'"); *see also* *Husqvarna AB v. EPA*, 254 F.3d 195, 200 (D.C. Cir. 2001) (great discretion to balance statutory factors in considering level of technology-based standard, and statutory requirement "[to give] appropriate consideration to the cost of applying ... technology" does not mandate a specific method of cost analysis); *Hercules Inc. v. EPA*, 598 F.2d 91, 106-07 (D.C. Cir. 1978) ("In reviewing a numerical standard, we must ask whether the agency's numbers are within a 'zone of reasonableness,' not whether its numbers

As noted above, EPA has found that the elevated concentrations of greenhouse gases in the atmosphere may reasonably be anticipated to endanger public health and welfare.²⁴¹⁸ EPA defined the “air pollution” referred to in CAA section 202(a) to be the combined mix of six long-lived and directly emitted GHGs: carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF₆). The EPA further found under CAA section 202(a) that emissions of the single air pollutant defined as the aggregate group of these same six greenhouse gases from new motor vehicles and new motor vehicle engines contribute to air pollution. As a result of these findings, section 202(a) requires EPA to issue standards applicable to emissions of that air pollutant. New motor vehicles and engines emit CO₂, CH₄, N₂O, and HFC. EPA has established standards and other provisions that control motor vehicle emissions of CO₂, HFCs, N₂O, and CH₄. EPA has not set any standards for PFCs or SF₆ as they are not emitted by motor vehicles.

3. EPA’s conclusion that the final CO₂ standards are appropriate and reasonable

In this section, EPA discusses the factors, data and analysis the Administrator has considered in the selection of the EPA’s revised CO₂ emission standards for MYs 2021 and later and the comments received on EPA’s consideration of these factors (see further discussion below on EPA’s summary and analysis of comments).

As discussed in Section VIII.A.1 above, the primary purpose of Title II of the Clean Air Act is the protection of public health and welfare, and GHG emissions from light-duty vehicles have been found by EPA to endanger public health and welfare.²⁴¹⁹ The goal of the light-duty vehicle GHG standards is to reduce these emissions which cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare, while taking into account other factors as discussed above.

CAA section 202(a)(2) states when setting emission standards for new motor vehicles, the standards “shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.” 42 U.S.C. 7521(a)(2). That is, when establishing emission standards, the Administrator must consider both the lead time necessary for the development of technology that can be used to achieve the emission standards and the resulting costs of compliance on those entities that are directly subject to the standards. In previous rulemakings, including the rulemaking that established the current standards, EPA considered lead time-related elements, including comparative per-vehicle cost increases by manufacturer for both cars and trucks, comparative penetration rates of advanced technologies by manufacturers

are precisely right”); *Permian Basin Area Rate Cases*, 390 U.S. 747, 797 (1968) (same); *Federal Power Commission v. Conway Corp.*, 426 U.S. 271, 278 (1976) (same); *Exxon Mobil Gas Marketing Co. v. FERC*, 297 F. 3d 1071, 1084 (D.C. Cir. 2002) (same).

²⁴¹⁸ 74 FR 66496 (Dec. 15, 2009).

²⁴¹⁹ *Id.*

for both cars and trucks, and lead time concerns about increasing technology penetration rates for these advanced technologies beyond current levels. EPA also considered comparative industry-wide costs and differences between alternatives, framed in terms of total costs and percentage differences between alternatives. These elements are discussed in detail throughout the analysis. As mentioned previously, however, the performance of the fleet in recent years indicates that the lead time deemed as adequate in the 2012 rulemaking was not sufficient.

EPA is not limited to consideration of the factors specified in CAA section 202(a)(2) when establishing standards for light-duty vehicles. In addition to feasibility and cost of compliance, EPA may (and historically has) considered such factors as safety, energy use and security, degree of reduction of both GHG and non-GHG pollutants, technology cost-effectiveness, and costs and other impacts on consumers.

EPA also considers relevant case law. Critical to this series of joint rulemakings with NHTSA, the Court in *Massachusetts v. EPA*²⁴²⁰, recognized EPA’s argument that “it cannot regulate carbon dioxide emissions from motor vehicles” without “tighten[ing] mileage standards . . .”—a task assigned to DOT. The Court found that “[t]he two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency.”²⁴²¹ Accordingly, the agencies have worked closely together in setting standards, and many of the factors that NHTSA considers to set maximum feasible standards overlap with factors that EPA considers under the Clean Air Act. Just as EPA considers energy use and security, NHTSA considers these factors when evaluating the need of the nation to conserve energy, as required by EPCA. Just as EPA considers technological feasibility, the cost of compliance, technological cost-effectiveness and cost and other impacts upon consumers, NHTSA considers these factors when weighing the technological feasibility and economic practicability of potential standards. EPA and NHTSA both consider implications of the rulemaking on CO₂ emissions as well as criteria pollutant emissions. And, NHTSA’s role as a safety regulator inherently leads to the consideration of safety implications when establishing standards. The balancing of competing factors by both EPA and NHTSA are consistent with each agency’s statutory authority and recognize the overlapping obligations the Supreme Court pointed to in directing collaboration.

As discussed in prior rulemakings setting GHG standards,²⁴²² EPA may establish technology-forcing standards under section 202(a), but it must provide a rationale for concluding that the industry can develop the needed technology in the available time. However, EPA is not *required* to set technology-forcing standards under section 202(a). Rather, because section

²⁴²⁰ 549 U.S. 497, 531 (2007).

²⁴²¹ *Id.* at 532.

²⁴²² *See, e.g.*, 77 FR 62624, 62673 (Oct. 15, 2012), EPA and NHTSA final rule for 2017 and later model year light-duty GHG emissions and CAFE standards.

202(a), unlike the text of section 202(a)(3) and section 213(a)(3),²⁴²³ does not specify that standards shall obtain “the greatest degree of emission reduction achievable,” EPA retains considerable discretion under section 202(a) in deciding how to weigh the various factors, consistent with the language and purpose of the Clean Air Act, to determine what standards are appropriate.

The proposed rule presented an analysis of alternatives, in support of the Administrator’s consideration of a range of alternative CO₂ standards as potential revisions of the existing standards for model years 2021 and later, from the previous standards (representing an increase in stringency of approximately 5 percent per year from MY 2021 through MY 2025) to several less stringent alternatives. These alternatives ranged from a zero percent increase in stringency to a stringency increase for passenger cars of 2 percent per year and for light trucks of 3 percent per year, in addition to the baseline alternative consisting of the previous standards.²⁴²⁴ The analysis supported the range of alternative standards based on factors relevant to the EPA’s exercise of its section 202(a) authority, such as emissions reductions of GHGs and other air pollutants, the necessary technology and associated lead-time, the costs of compliance for automakers, the impact on consumers with respect to cost and vehicle choice, and effects on safety. The proposed rule identified the alternative composed of a 0 percent increase in stringency as the preferred alternative.

EPA received numerous public comments on the range of stringency alternatives in the proposed rule and the Administrator’s consideration of various factors in determining appropriate GHG standards under section 202(a) of the CAA. Below EPA responds to comments on these issues. EPA notes that many comments concerned the technical foundation and analysis upon which EPA was basing its regulatory decisions, such as the modeling of emission control technologies and costs, the safety analysis, and consumer issues. Comments specific to these analyses are discussed elsewhere in this preamble. The section below addresses comments specifically addressing EPA’s considerations in finalizing appropriate CO₂ emissions standards under the CAA.

EPA’s conclusion, after consideration of the factors described below, public comments, and other information in the administrative record for this action is that holding CO₂ emissions standards for MY 2020 flat through MY 2026 is not appropriate or reasonable. EPA concludes steady stringency increases year over year are warranted, but that the MY 2021-2026 standards first established in 2012 are not appropriate taking into account lead time and the various factors

²⁴²³ Section 202(a)(3) provides that regulations applicable to emissions of certain specified pollutants from heavy-duty vehicles or engines “shall contain standards which reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available . . . giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.” 42 U.S.C. 7521(a)(3). Section 213(a)(3) contains a similar provision for new nonroad engines and new nonroad vehicles (other than locomotives or engines used in locomotives). 42 U.S.C. 7547(a)(3).

²⁴²⁴ 83 FR 42990, Table I-4 (August 24, 2018).

described below. Accordingly, the Administrator has concluded that 1.5 percent annual increases in stringency from the MY 2020 standards through MY 2026 (Alternative 3 of this final rule analysis)²⁴²⁵ are reasonable and appropriate.

a) *Consideration of the Development and Application of Technology to Reduce CO₂ Emissions*

When EPA establishes emission standards under CAA section 202, it considers both what technologies are currently available and what technologies under development may become available. For today's final rule, EPA considered the analysis of the potential penetration into the future vehicle fleet of a wide range of technologies that both reduce CO₂ and improve fuel economy (see FRIA Chapter X). The majority of these technologies have already been developed, have been commercialized, and are in-use on vehicles today. These technologies include, but are not limited to, engine and transmission technologies, vehicle mass reduction technologies, technologies to reduce aerodynamic drag, and a range of electrification technologies. The electrification technologies include 12-volt stop-start systems, 48-volt mild hybrids, strong hybrid systems, plug-in hybrid electric vehicles, and dedicated electric vehicles.

This consideration is especially important given current projections about relatively lower fuel prices than what was projected in 2012. In that rulemaking, EPA expressed concern that some alternatives may require too much advanced technologies (including electrification) in light of uncertain consumer acceptance of added costs, as well as the technologies themselves.²⁴²⁶ There, EPA concluded that more stringent increases in technology penetration rates raise serious concerns about the ability and likelihood that manufacturers can smoothly implement additional technologies to meet requirements.²⁴²⁷

As shown in Section VII of this preamble and in FRIA Chapter X, the projected penetration of technologies varies across the Alternatives considered for this final rule. In general, the baseline alternative consisting of the previous EPA standards as finalized in 2012 was projected to result in the highest penetration of advanced technologies into the vehicle fleet, in particular mild hybrids at 7.1 percent penetration and strong hybrids at 9 percent penetration by MY 2030. By contrast, the revised final standards adopted today (1.5 percent per year stringency improvement from MY 2021 through MY 2026) are projected to result in a significantly lower level of mild and strong hybrids used to meet the standards, at 1.6 percent

²⁴²⁵ The numbered Alternatives presented in the SAFE proposed rule (see Table I-4 at 83 FR 42990, August 24, 2018) were in some cases defined differently than those presented in this final rule (see [X]). Unless otherwise stated, the Alternatives described in this section refer to those presented in this final rule.

²⁴²⁶ 77 FR 62879.

²⁴²⁷ See 77 FR at 62875, discussion about certain alternatives may require too much electrification and "may well be overly aggressive in the face of uncertain consumer acceptance of both the added costs and the technologies themselves. EPA continues to believe these technology penetration rates are inappropriate given the concerns just voiced." At 62877, "This increase in tech penetration rates raises serious concerns about the ability and likelihood manufacturers can smoothly implement...."

mild hybrids and 2.2 percent strong hybrids by MY 2030. Further, the final rule analysis indicates that the previous CO₂ standards would have led to a projected 5.7 percent penetration of dedicated electric vehicles (EV), with 0.4 percent penetration of plug-in hybrid electric vehicles (PHEV); the revised final standards reduce this projected level to 3.7 percent EV penetration (with 0.2 percent PHEV penetration), which again is more in line with what the EPA believes is a more appropriate projected level of market penetration.

The technology penetration rates in the analysis for the final rule are changed since EPA's prior analysis. These changes in the estimated penetrations in this rulemaking are due to changes in the model that are meant to reflect consumer response to the standards, as well as changes to estimates for technology costs and effectiveness. In the 2017 Final Determination on Model Year 2022-2025 standards, where EPA found there was available and effective technology to meet the MY 2022-2025 standards, the technology was available at reasonable cost to the vehicle manufacturers and consumers, there was adequate lead time, and the standards were feasible and practicable. EPA also found that the previous MY 2022-2025 standards could be met largely through advanced gasoline vehicle technologies, with low levels of electrified vehicles.²⁴²⁸ The levels of electrified vehicle technologies projected in this final rule to meet the baseline Alternative (the previous GHG standards) differ slightly from those projected in the 2017 Final Determination. In this final rule, EPA projects a combined strong and mild hybrid penetration of 18 percent (compared to 20 percent in the 2017 Final Determination), with the share of mild hybrids somewhat lower (8 percent compared to 18 percent in the 2017 Final Determination) and the share of strong hybrids higher (10 percent compared to 2 percent in the 2017 Final Determination). EPA projects a total level of plug-in vehicles of 5 percent, the same as the total projected in the 2017 Final Determination, but with a slightly different mix of plug-in hybrid electric vehicles (0 percent compared to 2 percent in the 2017 Final Determination) and dedicated electric vehicles (5 percent compared to 3 percent in the 2017 Final Determination).

Another aspect of the analysis that EPA considered related to technology development and application is manufacturers' projected level of over-compliance under the alternatives considered for the final rule. Under the least stringent Alternatives (Alternative 1, zero percent stringency improvement, and Alternative 2, 0.5 percent per year stringency improvement), manufacturers overall are projected to over-comply with those levels of stringency. For example, under Alternative 1, manufacturers are projected to achieve a CO₂ level of 206 g/mi in MY 2029, 18 g/mi below (more stringent than) the required target level of 224 g/mi. Similarly, for Alternative 2, manufacturers are projected to achieve a CO₂ level of 205 g/mi in MY 2029, 13 g/mi below the required target level of 218 g/mi. Thus, the industry is projected to considerably over-comply with the Alternative 1 and 2 standards. Under the final standards, the projected level of over-compliance is much narrower, only 5 g/mi (199 g/mi by MY 2029 compared to a 204 g/mi target), and for other alternatives that are more stringent than the final

²⁴²⁸ "Final Determination on the Appropriateness of the Model Year 2022-2025 Light-Duty Vehicle Greenhouse Gas Emissions Standards under the Midterm Evaluation," EPA-420-R-17-001, January 2017. See Table ES-1, page 4-5, and Section II (i), (ii), and (iii), pages 28-24. Hereafter "2017 Final Determination."

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

standards, that gap is similar or even more narrow. See Table X. This is an indication that the standards in Alternatives 1 and 2 may not represent an appropriate level of stringency when compared to the pace at which manufacturers would be applying technologies. While some level of over-compliance is expected so that manufacturers retain a reasonable compliance margin, Alternatives 1 and 2 would, based on the final rule analysis, result in manufacturers retaining a compliance margin more than 2-3 times that of the other alternatives. The Administrator has rejected those lower stringency Alternatives in part for this reason and believes that the final standards (Alternative 3, 1.5 percent per year stringency improvement) represent an appropriate margin of compliance that can be attained given the projected pace of manufacturers' application of technologies.

EPA received several comments regarding its consideration of the development and application of GHG reducing technologies. The California Air Resources Board (CARB) commented that, despite what they characterize as evidence of widely available technology, EPA has proposed to promulgate emission standards that are less stringent than existing standards and that would lead to increased emissions of GHGs. The New York State Department of Environmental Conservation commented that the proposal did not "appropriately value, or consider, technology advancement and innovation by OEMs and automotive parts suppliers" and noted the role of technology innovation in reducing technology costs. EPA notes that the agencies specifically considered technology cost-savings attributable to experience with technology—in other words, the analysis provides that technology costs reduce over time.

The Center for Biological Diversity (CBD) et al. commented that since technologies exist today that can achieve the current standards, reducing the standards to the level proposed in the NPRM is contrary to the objectives of the Clean Air Act. These parties further commented that EPA failed to make a proposed finding that additional lead-time is necessary, as they argue is required by Section 202(a)(2). The Green Energy Institute at Lewis and Clark Law School and others similarly commented that EPA lacks a reasonable justification for extending the phase-in period for the current standards because compliant technologies currently exist and are already commercially available.

The Attorney General of California and others commented that EPA acknowledges that most or all technology necessary to meet the current standards is available, and does not provide evidence to support how additional lead time is "necessary to permit the development and application of the requisite technology."

In response to the public comments, and as EPA indicated in the proposal and in the 2012 Final Rule establishing the previous standards, the technologies projected to be used to meet the GHG standards, including the alternatives in the proposal as well as the final standards, are currently available and in production. If the appropriateness of the standards were based solely on an assessment of technology availability, and lead time considerations were limited to the development of such technology, EPA might consider more stringent CO₂ standards to be potentially appropriate. But this is not the sole or predominant factor to be weighed. In 2012, EPA had to balance this issue as well. As in 2012, manufacturers today are capable of building

vehicles that can meet the standards that any of the regulatory alternatives evaluated in the final rule would require. However, greater uncertainty about consumer acceptance of those technologies (as compared to what EPA believed was likely in 2012) means that providing more lead time is appropriate.²⁴²⁹

As in 2012, EPA disagrees with commenters that a finding that necessary technology is available is, by itself, determinative of the appropriate emission standard under CAA section 202(a). As described in the proposed rule and in this section of the final rule, the Administrator weighs technology availability and lead time along with several other factors, including costs, emissions impacts, safety, and consumer impacts in determining the appropriate standards under section 202(a) of the CAA. Under this analysis, given the factors discussed later in this Section, the previous standards would yield technology penetration rates for advanced technologies beyond what is appropriate and reasonable. The final standards will achieve an increased level of technology penetration compared to the MY 2020 standards. For example, the analysis projects that dynamic cylinder deactivation penetration would be 39.2 percent under the previous standards for MY 2030, but 34.4 percent under today's final standards. Similarly, turbocharged engine penetration would be a projected 48 percent under the previous standards, compared to 36.4 percent by MY 2030 under the final standards. In addition, mild hybrids are projected to reduce from 7.1 percent to 1.6 percent, strong hybrids from 9 percent to 2.2 percent, and dedicated electric vehicles from 5.7 percent to 2.8 percent (all for MY 2030) under the final standards instead of the currently-final standards. The Administrator believes that the level of technology development and application is an appropriate balance, in light of the relevant factors considered as a whole, as discussed below.

b) Consideration of the Cost of Compliance

EPA is required to consider costs of compliance when setting standards under section 202(a). The standards finalized today would reduce required technology costs for the industry by an estimated \$107 billion for the vehicles produced from MY 2017 through MY 2029 (at 3 percent discount rate, see Section X) compared to the EPA standards established in 2012. While less-stringent increases would result in additional technology cost savings (\$125 billion and \$123 billion for Alternatives 1 and 2, respectively), technology cost savings are only one element that EPA considers.

In addition to capital cost savings, the final standards would reduce the per-vehicle technology costs by \$1,063 per vehicle in MY 2030, compared to the standards set in 2012, as shown in [Section X]. While less-stringent increases would result in greater per-vehicle technology cost-savings, cost-savings alone do not dictate the appropriate standards. For example, Alternatives 1 and 2 would save manufacturers \$1,275 and \$1,253 in per-vehicle costs

²⁴²⁹ See 77 FR at 62871 ("As stated above, EPA's analysis indicates that there is a technology pathway for all manufacturers to build vehicles that would meet their final standards as well as the alternative standards. The differences between the final standards and these analyzed alternatives lie in the per-vehicle costs and the associated technology penetration rates.").

in MY 2030 compared to the previously issued standards. Alternatives more stringent than the final standards would be more burdensome to manufacturers, with Alternatives 4 through 8 ranging from a cost savings to manufacturers of \$1,020 to \$478 per-vehicle compared to the previous standards.

The costs to comply projected in this final rule are higher than those previously projected by EPA in the 2017 Final Determination: In 2017 EPA projected that the per-vehicle cost to meet the MY 2025 standards would be \$875 on average, with a range of \$800 to \$1,115 considering a range of sensitivities (in 2015 dollars).²⁴³⁰ The costs to the auto industry for complying with the previous MY 2022-2025 standards projected in the 2017 Final Determination were \$24 billion to \$33 billion (in 2015\$ at 7 percent and 3 percent discount rates, respectively).²⁴³¹ Again, EPA notes that the values in this final rule analysis and the values in the 2017 Final Determination have different points of reference making them not directly comparable, as discussed above.

Several public comments addressed EPA's consideration of costs of compliance in setting the revised standards. The Alliance of Automobile Manufacturers (Alliance) commented that the proposal's cost estimates for the current MY 2021 and later standards differed from what EPA projected in 2012 when setting those standards. The Alliance argued that those changes in the expected costs of the previously issued standards provide significant reasoned support for EPA's view that the existing standards should be reduced.

The Association of Global Automakers (Global Automakers) commented on the importance of lead time for technology investment. While it agreed that the existing standards are too stringent, it stated that vehicle manufacturers and suppliers have invested \$76 billion in manufacturing facilities, and that much of that was for improvement in CO₂ emission reductions and fuel economy improvements. At least some of that investment, according to Global Automakers, was made to meet the standards set in 2012. Global Automakers expressed concern with an abrupt halt to gradual fuel economy improvements, as such an approach could result in stranded capital investments for automakers and suppliers.

CBD and others disagreed with EPA's conclusion that the cost of broader adoption of technologies is unreasonable in light of other factors considered by EPA. CBD and others claimed that the Clean Air Act narrowly allows for consideration of cost only as a question of whether costs of compliance make it infeasible for manufacturers to meet standards within the relevant period. They argue that this consideration relates to lead time, and not to a broader consideration of costs. They assert that broader compliance cost considerations apply only to the motor vehicle industry. They also claim that compliance costs to meet the standards set in 2012 for the 2017-2025 model years are not challenging to the industry.

²⁴³⁰ See 2017 Final Determination Table ES-1, page 4-5, and II(v), page 24-26.

²⁴³¹ *Id.* at Table ES-4, page 7.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

These commenters also state that the costs to industry to meet the standards are not high enough to require reducing standards, to permit development and application of the required technology. They claim that the only burden that Congress intended to impose as a constraint on emission reduction requirements are costs that are “so severe as to preclude the deployment of required technology during the relevant period.”

The New York State Department of Environmental Conservation commented on the role of technology innovation in considering technology feasibility, while acknowledging that the feasibility analysis allows for consideration of numerous factors argues that since technology exists today to meet the standards for MY 2026, no lead time is necessary. It further states that EPA did not appropriately balance or consider in the proposal future technological advancements and OEM innovation that will further constrain the costs of new technology.

In response to the Alliance’s comment that the projected compliance costs have changed significantly from EPA’s 2012 rule, EPA agrees. Indeed, this is a significant factor in EPA’s conclusion that the previous standards were too stringent. EPA notes that the projected difference between the cost to comply with the previous standards and the costs to comply with the standards established today is lower in this final rule analysis as compared to the projected difference between the proposal’s preferred alternative and the previous standards. EPA concludes that the final standards nevertheless result in significant reductions in required technology costs for auto manufacturers compared to the previous standards.

EPA also considered the Global Automakers’ concern that freezing the standards from MY 2021-2026 as proposed could result in stranded capital for the auto industry and automotive suppliers who have invested significantly in meeting the previous standards. The standards EPA is finalizing today, unlike the proposed preferred alternative, will require the gradual increase in CO₂ improvements across the fleet, at a rate of 1.5 percent per year stringency improvement, thus supporting investments in GHG-reducing technologies, at a pace that EPA believes is more reasonable than that of the previous standards.

EPA disagrees with CBD et al.’s comments that the agency’s consideration of costs is inappropriate or not supported by the record. EPA disagrees that Congress intended section 202(a)(2)’s requirement to give “appropriate consideration to the cost of compliance within such period” to mean that the agency “only consider compliance costs if they are so severe as to preclude deployment of the requisite technology during the period.” EPA does not interpret the Clean Air Act as limiting EPA’s consideration of costs to manufacturers only to the question of whether such costs make a particular standard infeasible to achieve for a given model year—that would be tantamount to suggesting that EPA must always set a technology-forcing standard, which as discussed above is not EPA’s approach to setting standards such as these under section 202(a). And this is particularly important when setting CO₂ standards, which, as described above, have a significant impact on vehicle utility and performance that differs from other standards established under Section 202. As discussed above, Congress specified such technology-forcing standards elsewhere in section 202 and could have done so here (or otherwise specified that standards shall take effect “as soon as practicable” while taking into consideration costs and other factors) – but did not do so. Section 202(a) prevents EPA from implementing

standards sooner than feasible, taking into account lead time considerations and the cost of compliance, but does not require standards be implemented as soon as feasible or at the limit of feasibility, taking into account the cost of compliance. EPA notes that it received numerous comments on the analysis underlying the proposed rule, and the analysis for this final rule in fact was changed from the proposal in consideration of these comments, as discussed in [section X]. Nevertheless, the projected costs to comply with the previous MY 2021-2026 standards remain significant as discussed above, and EPA has considered these costs along with other factors under the CAA in determining the final standards, as discussed in section VIII.A.2.g below.

c) Consideration of Costs to Consumers

In this section EPA considers the cost impacts on consumers. First, the initial up-front costs to consumers are discussed, then the costs associated with fuel expenditures, and finally the total ownership costs to consumers over the life of the vehicles.

In addition to the \$1,063 per-vehicle technology costs to the automotive industry described above, which EPA expects could, and likely would, be passed on to consumers, the analysis estimates other per-vehicle costs that could be borne by consumers, specifically costs attributed to changes in financing, insurance, taxes, and other fees, as shown in [X]. Considering these additional costs, EPA's final standards (Alternative 3) would result in reduced costs to consumers of \$1,385 in MY 2029 (at a 3 percent discount rate) compared to EPA's previously issued standards. While alternatives lower in stringency than the final standards would save consumers more (i.e., Alternatives 1 and 2 would save consumers \$1,665 and \$1,637, respectively, in MY 2029 at 3 percent discount rate), while alternatives more stringent than the final standards would save consumers less (i.e., Alternatives 4 through 7 would save consumers a range of from \$1,329 to \$620, for MY 2029 at 3 percent discount rate), this is only one of the factors EPA considers in setting standards. On balance, EPA believes that further increases in stringency, compared to the proposal, are appropriate and reasonable.

Compared to the previously issued CO₂ standards, the standards finalized today will result in increased fuel consumption and associated expenditures for consumers. The analysis detailed in the Final RIA and summarized in section VII of this preamble projects the increased fuel consumption for owners of the vehicle over the projected life of the vehicle, up to 39 years, as compared to the previously issued standards as the baseline. For example, as shown in [X] (at a 3 percent discount rate), consumers will spend \$1,609 more in fuel costs over the vehicle lifetime, which the analysis assumes can be up to 39 years, under today's final standards (Alternative 3) compared to the previously issued standards.

EPA notes that, when comparing lifetime fuel savings for all owners of a vehicle to the upfront additional ownership costs—generally borne by the initial purchaser, a net reduction in benefits of \$712 is seen under the final standards. That said, as noted by several commenters, consumers keep vehicles for a much shorter period of time prior to trading the vehicle in for

another or selling the vehicle.²⁴³² CFA, for instance mentioned that consumers retain vehicles for more than five years, and a group of State Comptrollers and Treasurers referred to an IHS Markit report that the average length of time a consumer keeps a new car is approximately 6.6 years. Accordingly, such a simplistic comparative approach would anticipate that a consumer account for fuel savings over a much longer period of time than would be rational. Further, it is important to note that consumers are informed of estimated average annual fuel costs for the vehicle, as well as a comparison of the difference between five years'-worth of fuel costs or savings compared to an average new vehicle on the Monroney label that must be posted on every new vehicle offered for sale.

In the 2017 Final Determination, EPA projected that the previous MY 2022-2025 standards compared to the MY 2021 standards would provide fuel savings of \$52 billion to \$92 billion and total net benefits of \$59 billion to \$98 billion (in 2015 dollars and at 7 percent and 3 percent discount rates, respectively, and based on AEO2016 reference case fuel prices). The up-front vehicle costs to consumers were projected to be approximately \$926 per vehicle, including the vehicle technology costs, taxes and insurance.²⁴³³ EPA projected that consumers would realize net savings of \$1,650 over the lifetime of a new MY 2025 vehicle (net of increased lifetime costs and lifetime fuel savings).²⁴³⁴ Under the final standards, vehicle sales are expected to increase by 2.2 million vehicles over MY 2017-2029 compared to projected sales under the previous standards. EPA views this projection of vehicle sales increases resulting from the final standards as important in facilitating the turnover of the fleet to newer, safer vehicles, all of which will be subject to increasingly stringent criteria pollutant emission requirements as federal Tier 3 emission standards continue to phase in from MY 2017 through MY 2025.

Below the major comments are summarized regarding EPA's consideration of the impact of the revised standards on consumers. Securing America's Future Energy (SAFE) commented that vehicle prices are influenced by many factors beyond the GHG standards, and that costs to improve fuel economy make up only a portion of the vehicle price. SAFE notes that fuel savings from efficient vehicles offsets increase ownership costs. SAFE further claims, without support, that standards "do not have a major role in creating higher vehicle prices, or in suppressing sales." Accordingly, SAFE argues that pausing fuel economy increases, as proposed in the NPRM, is not justified. SAFE suggests that fuel savings impacts should be discussed along with technology cost increases.

CBD and others commented that EPA's consideration of consumer costs, including finance and insurance costs, cannot outweigh its public health mandate. Such commenters noted that some of the options analyzed in the notice showed that fuel

²⁴³² It should be noted, however, that, all else being equal, improved fuel economy can improve resale value of a vehicle. That said, it is not at all clear that consumers generally anticipate potential future incremental trade-in value attributable to improved fuel economy when making a decision as to which new vehicle to purchase.

Again, note the different points of reference for the values presented in this final rule and the 2017 Final Determination in, as discussed above.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

savings of the lifetime of the vehicle outweighed upfront vehicle price increases, and that not choosing such an alternative is not justified. CBD then goes on to argue that the analysis inflates technology costs and undercounts fuel savings.

The California Attorney General and others claim that EPA's consideration of the potential increased costs for consumers related to maintenance, financing, insurance, taxes, and other fees is unjustified, unlawful, and contrary to its prior position that compliance cost considerations include only costs to the motor-vehicle industry.

EPA notes that fuel efficiency and GHG standards affect labor and materials costs, technology add-ons, and sales mix, and expects the estimated cost decrease from these final standards to have a positive effect on the auto market and vehicle buyers. As described in the notice and throughout this preamble, EPA disagrees that standards have no major impact on increasing prices or suppressing sales. Fuel-saving technology adds costs, and as prices increase, fewer consumers can afford to buy new cars—either because they cannot afford a new car, or because they decide to purchase an older vehicle, or because they decide to keep their existing vehicle. EPA also notes that both the notice and this preamble discusses fuel savings from the various alternatives analyzed. Some commenters suggest EPA calculate and consider fuel savings, spread over the lifetime of the vehicle up to 39 years and experienced by multiple owners—compared to the upfront vehicle costs, which are generally paid for by the original purchaser either in cash or through additional finance costs over a much shorter period of time. This approach, which would yield a projected \$712 in additional fuel consumption costs over the multi-owner, lifetime of a vehicle beyond the initial ownership savings, distorts the comparison. Instead, EPA concludes that the upfront vehicle technology costs (and associated financing costs) are a more important factor. In other words, a consumer is more likely to buy a new vehicle at a lower up-front price even if that vehicle will incur a more-than offsetting level of fuel costs over its lifetime that will be borne by the first and all subsequent owners of the vehicle. By reducing upfront costs, more consumers will be able to afford new vehicles, which will result in a quicker fleet turnover to safer, more efficient vehicles that emit lower amounts of criteria pollutants than the existing fleet. In fact, the agencies project that the revised standards will result in 2.2 million additional new vehicles sold—all of which would meet the latest safety standards and be subject to the phase-in of the Tier 3 criteria pollutant emission standards.

With respect to the comments that consideration of costs to consumers is contrary to CAA section 202(a)(2), EPA disagrees. As discussed above, section 202(a)(2) requires EPA to consider the cost of compliance, which EPA has done, and it allows EPA to consider other costs, including costs to consumers, which EPA also have done, in this rule and past rules setting standards under section 202(a). The statute sets some minimum requirements for EPA's consideration, but permits a wider range of concerns to be considered, including public health and welfare but also safety, costs to consumers, and other factors discussed herein. As discussed above, and below, EPA has considered the effects of a range of potential standards across this entire set of factors. The agency is permitted to take all of these factors into account, and that is what it has done in selecting the final standards.

d) *Consideration of GHG Emissions and Other Air Pollutant Emissions*

As discussed above, the purpose of GHG standards established under CAA section 202 is to reduce GHG emissions, which EPA has found to endanger public health and welfare, in an appropriate manner that takes into account other factors as directed by Congress and in the reasonable exercise of EPA's discretion under the statute. Today's final standards are projected to increase CO₂ emissions compared to the previously issued standards, by a total of 876 million metric tons (MMT) over the lifetime of MY 1977 through MY 2029 vehicles (see Section VII of this preamble). Of this CO₂ emissions increase, 740 MMT would come from tailpipe emissions, and an additional 136 MMT from upstream sources. The analysis projects that Alternatives more stringent than the final standards would result in smaller increases in CO₂ emissions. Compared to the previous standards, Alternatives 4 through 7 are projected to increase CO₂ emissions by 834 MMT to 414 MMT (combined vehicle tailpipe and upstream reductions over the lifetime of the MY 1977-MY 2029 vehicles). Alternatives less stringent than the final standards would increase CO₂ emissions by a greater amount, 1,045 MMT and 1,022 MMT, for Alternatives 1 and 2 respectively.²⁴³⁵

In addition to GHG emissions, EPA has considered the change in criteria air pollutant emissions impacts due to the revised CO₂ standards. EPA has considered both tailpipe emissions and upstream emissions associated with increased fuel consumption. Unlike with CO₂ emissions, which EPA found to be a long-lived greenhouse gas well-mixed throughout the global atmosphere, criteria pollutant emissions contribute primarily to local and regional air pollution. Generally, tailpipe emissions for volatile organic compounds (VOC), nitrogen oxides (NOx), and particulate matter (PM) decrease under the final standards compared to the previous standards, leading to improvements in human health in areas where air quality improves. Upstream emissions attributable to refining and transportation of the additional fuel needed under less stringent standards increase under the final standards, leading to adverse impacts on public health in locations where air quality worsens. The additional upstream emissions generally exceed the reduced tailpipe emissions, leading to net increases in these pollutants and net increases in adverse health effects. Under the model year analysis (changes in pollutants summed over the lifetimes of MY 1977-2029 vehicles for calendar year 2017 and later), VOC emissions will increase by 154,215 tons, NOx emissions will increase by 29,370 tons, SO₂ emissions will

²⁴³⁵ This preamble and the FRIA document estimate annual GHG emissions from light-duty vehicles under the baseline CO₂ standards, the final standards, and the standards defined by each of the other regulatory alternatives considered. For the final rule issued in 2012, EPA estimated changes in atmospheric CO₂, global temperature, and sea level rise using GCAM and MAGICC with outputs from its OMEGA model. Because the agencies are now using the same model and inputs, outputs from NHTSA's EIS (that used more recent versions of GCAM and MAGICC) were analyzed. Today's analysis estimates that annual GHG emissions from light-duty vehicles under the CO₂ standards and corresponding CAFE standards, which are very similar. Especially considering the uncertainties involved in estimating future climate impacts, the very similar estimates of future GHG emissions under CO₂ standards and corresponding CAFE standards means that climate impacts presented in NHTSA's EIS represent well the climate impacts of the CO₂ standards.

increase by 20,370 tons, and PM emissions will increase by 5,340 tons. [Potential narrative comparison forthcoming].

In addition to evaluating emissions impacts under the model year analysis described above, EPA has considered the emissions impacts under a calendar year analysis, which provides information over a longer time horizon about the interactions between all vehicle model years on the road in any given calendar year – that is, considering the effects of the revised MY 2021 and later standards on fleet turnover and utilization from calendar year 2017 out to 2050. Both the model year analysis and the calendar year analysis provide relevant information about the impacts of EPA's standards. When viewed from the calendar year analysis perspective, the emissions impacts of the revised MY 2021 and later standards compared to the previous standards for the period from calendar year 2017 to 2050 are generally larger: VOC emissions will increase by 602,650 tons, NOx emissions will increase by 184,770 tons, and PM emissions will increase by 17,370 tons; SO2 emissions will decrease by 53,625 tons. [Potential narrative comparison forthcoming].

As shown in the NHTSA Final Environmental Impact Statement (FEIS), chapter X, NHTSA's analysis indicates small air quality improvements in some areas and small decrements in others which could help or hinder individual areas' efforts to attain the NAAQS in the future.

EPA has also considered the health effects of air pollution associated with today's final standards. The analysis projects increases in premature deaths, asthma exacerbation, respiratory symptoms, non-fatal heart attacks, and a wide range of other health impacts, due to the increases in air pollutant emissions under today's final standards as well as under the alternatives, compared to the previously issued standards. These health impacts are detailed in [section XX] of this preamble. The analysis projects that the air pollution emission increases associated with the revised standards will lead to an increase of 440 to 990 premature deaths—deaths that occur before the normally expected life span—compared to the standards established in 2012 over the lifetime of the MY 1977-MY 2029 vehicles. In addition, a wide range of health impacts are projected to increase under the final standards compared to the standards established in 2012 [see Table X]. Specifically, under the final standards as compared to the previous standards, using the model year analysis (over the lifetimes of MYs 1977-2029 vehicles beginning in calendar year 2018), upper and lower respiratory symptoms are expected to increase by 21,000 cases, asthma exacerbations are projected to increase by 14,000 cases, acute bronchitis cases are projected to increase by 670, non-fatal heart attacks are projected to increase by 490, hospital admissions for cardiovascular and respiratory issues are projected to increase by 230 cases, and emergency room visits for respiratory issues are projected to increase by 230. In addition, these health impacts are expected to result in 58,000 work loss days and 330,000 minor restricted activity days for the public. [Potential narrative comparison forthcoming].

When quantified using the calendar year (CY) analysis perspective (CYs 2018-2050), under the revised final standards (compared to the previous standards), premature mortality is expected to increase from 350 to 760 deaths, upper and lower respiratory symptoms are expected to increase by 17,000 cases, asthma exacerbations are projected to increase by 12,000 cases, acute bronchitis cases are projected to increase by 560, non-fatal heart attacks are projected to

increase by 370, hospital admissions for cardiovascular and respiratory issues are projected to increase by 170 cases, and emergency room visits for respiratory issues are projected to increase by 200. In addition, these health impacts are expected to result in 47,000 work loss days and 270,000 minor restricted activity days for the public. Compared to the MY 2019 standards, instead of reducing premature deaths by [X percent], this rule will reduce premature deaths by [Y percent]. Upper and lower respiratory symptoms will reduce by [X percent] instead of [Y percent], asthma exacerbations will reduce by [X percent] instead of [Y percent], acute bronchitis cases will reduce by [X percent] instead of [Y percent]. Hospital admissions for cardiovascular and respiratory issues will reduce by [X percent] instead of [Y percent]. Emergency room visits will reduce by [X percent] instead of [Y percent]. Health impact-related work loss days will reduce by [X percent] instead of [Y percent]. Minor restricted activity days for the public will reduce by [X percent] instead of [Y percent].

In the 2017 Final Determination, EPA projected GHG emissions reductions of 540 million metric tons over the lifetimes of MY 2022-2025 vehicles.²⁴³⁶ EPA also projected criteria pollutant emission reductions for CY2040 of 97,000 tons of VOC, 24,000 tons of NOx, 3,600 tons of PM_{2.5}, and 15,000 tons of SO₂.²⁴³⁷ EPA projected that these emissions reductions would result in positive health benefits through CY2050.²⁴³⁸ In this final rule, the revised final standards compared to the previous standards are projected to result in an increase in emissions and health incidences, as discussed above, resulting in negative \$3 billion to negative \$5 billion (7 percent and 3 percent discount rates, respectively, 2018\$) in public health benefits [see X].

In public comments on these topics, the Attorney General of California and others commented that, in adopting the previous standards, EPA focused on obtaining significant CO₂ emission reductions, but now proposed to increase emissions relative to the previous standards without sufficient justification. They claim that EPA offered no justification of acknowledgement of a change in position, stating that none of the alternatives further the goal of CO₂ emission reductions. They argue that EPA justifies its proposal on the limited impact of the rule on global climate change, and that failing to seek incremental improvements is contrary to the EPA's duties under the Clean Air Act.

The United States Conference of Catholic Bishops commented that considering public safety of any set of standards requires giving significant weight to the effect of air pollution, and that the proposal failed to promote public health and safety.

The Chesapeake Bay Foundation (CBF) claims that the proposal would have significant health consequences that disproportionately impact minority and low-income communities in the Chesapeake Bay. They discuss general impacts of climate change. CBF argues that criteria

Commented [A1]: When will these numbers be filled in? Will there also be an accompanying analysis of why—whatever the numbers are—the rule is justified?

Commented [A2]: Is there any analysis to add concerning why, notwithstanding these changes, the rule is appropriate?

²⁴³⁶ 2017 Final Determination at Table ES-3, page 6, and Section II (iv), page 24.

²⁴³⁷ 2016 Proposed Determination at Appendix C, Table C.54, page A-163.

²⁴³⁸ *Id.* at Table C.87, page A-183.

pollutant health impacts of the proposal, should be more heavily weighed against safety impacts of the rule.

The State of Washington commented that the agencies did not analyze public health effects from increased criteria pollutant emissions arising from increased petroleum consumption or environmental justice concerns. They claim that the NPRM's discussion of the negligible impact of the rulemaking on global climate change is "deeply concerning."

As noted above, EPA agrees that the purpose of Title II emission standards is to protect the public health and welfare from air pollution, and in establishing emission standards, the agency is cognizant of the importance of this goal. At the same time, EPA balances multiple factors in determining what standards are reasonable and appropriate. And, contrary to some commenters' views, unlike other provisions in Title II, section 202(a) does not require the Administrator to set standards which result in the greatest degree of emissions control achievable. Thus, in setting these standards, the Administrator has taken into consideration other factors discussed above and below, including not only technological feasibility, lead-time, and the cost of compliance, but also potential impacts of vehicle emission standards on safety and other impacts on consumers.

Several commenters claimed that the agencies did not analyze health impacts of the various alternatives, but this is not accurate. First, the notice and PRIA included this information in monetized terms to facilitate the balancing of various factors. Further, NHTSA conducted a comprehensive Draft Environmental Impact Statement, which discussed these effects in detail. For this final rule, these health impacts have been separately itemized, as summarized above and discussed in [Section XXX]. Other commenters claimed that the agencies did not sufficiently consider environmental justice elements in the proposal. This, too, is inaccurate, as discussed in [Section XXX].

In response to comments of the California Attorney General and others, that the Clean Air Act cannot allow for increases in a regulated emission, EPA notes that the 2012 Final Rule specifically called for a Mid Term Evaluation process that envisioned the potential for an adjustment of the standards in case the stringency increases established in 2012 were no longer reasonable and appropriate. As discussed [above], the increases in stringency of the standards for MY 2021-2025 are, on balance, not reasonable and appropriate based on a consideration of the factors described in this preamble. EPA now recognizes based on updated information and analysis that industry should be provided additional lead time to meet the later model years of standards set in the 2012 rule, and, as discussed in this preamble, industry is having unanticipated difficulties complying with earlier years of the standards, with fleetwide performance failing to meet CO₂ emission targets in MY 2016 and MY 2017. That is not to say that CO₂ and criteria pollutant emissions are not significant factors in this rulemaking. Indeed, they are weighed heavily along with other important factors considered by EPA, which has led to increasing stringency on a 1.5 percent annual basis for the 2021-2026 model years. Importantly, the agencies project that the revised standards will result in an additional 2.2 million new vehicles sold compared to the previous standards. This means that an additional 2.2 million vehicles will be on the road during the phase-in of the Tier 3 emission standards, which will

Commented [A3]: What information and analysis? This discussion of rationale seems thin.

provide significant health benefits. As discussed, when finalizing the Tier 3 standards in 2014, “[t]he final Tier 3 vehicle and fuel standards together will reduce dramatically emissions of NOx, VOC, PM2.5, and air toxics.”²⁴³⁹

Commented [A4]: Is there any quantification of this?

Although GHG emissions reductions would be lessened under the standards finalized today compared to the previously issued EPA standards, in light of this assessment indicating higher vehicle costs and associated impacts on consumers, EPA believes that, on balance, the final standards (Alternative 3) are justified and appropriate.

Commented [A5]: This is awkward phrasing—talking about reductions being lessened.

e) Consideration of Consumer Choice

As discussed previously, the EPA CO₂ standards are based on vehicle footprint, and in general smaller footprint vehicles have individual CO₂ targets that are lower (more stringent) than larger footprint vehicles. The passenger car fleet has footprint curves that are distinct from the light-truck fleet. One of EPA’s goals in designing the footprint-based standards, in considering the shape, slope, and stringency of the footprint standard curves, and in adopting various compliance flexibilities (e.g., emissions averaging, banking, and trading, air-conditioning credits, off-cycle credits) was to maintain consumer choice. The EPA standards are designed to require reductions of CO₂ emissions over time from the vehicle fleet as a whole, but also to provide sufficient flexibility to the automotive manufacturers so that firms can produce vehicles that serve the needs of their customers. The past several model years in the marketplace show that, while this approach reduces the impact of increased fuel economy on consumer choice, it does not adequately account for changes in consumer preference. As a result, as discussed throughout this preamble, manufacturers are struggling to meet CO₂ emission standards based upon their fleet performance. In fact, the 2017 model year saw that only three major manufacturers had fleets that met the standards. One reason behind these challenges is that, while the footprint-based attribute standards account for vehicle length and width, they do not account for vehicle height or weight. And, since many crossovers sold today are classified as passenger cars and not light trucks, the additional weight of such vehicles to provide for requisite ride height puts pressure on CO₂ emission compliance for automaker passenger car fleets. Similarly, large SUVs are subject to the same footprint-based standards as lighter trucks, putting pressure on CO₂ emission standard compliance. For the 2017 model year, 12 percent of the fleet consisted of car-based SUVs, and 32 percent of the fleet consisted of truck-based SUVs.²⁴⁴⁰ Taller and heavier vehicles (including crossovers and SUVs) are more popular today than was expected at the time the standards were set. While automobile manufacturers have continued to offer a broad range of vehicles (e.g., full-size pick-up trucks with high towing capabilities, minivans, cross-over vehicles, SUVs, and passenger cars; vehicles with off-road capabilities; luxury/premium vehicles, supercars, performance vehicles, entry level vehicles, etc) despite continuing required increases in fuel economy stringency, this has largely been possible because of well-stocked over-compliance credit banks from when standards were less stringent and the

²⁴³⁹ 79 FR 23425.

²⁴⁴⁰ [Cite 2018 Trends Report]

ability to acquire credits from other manufacturers. As mentioned earlier, the agencies have concerns whether this is sustainable. Automotive companies have been able to reduce their fleet-wide CO₂ emissions while continuing to produce and sell the many diverse products that serve the needs of consumers in the market. Considering these challenges, the fact that automotive customers are diverse, that automotive companies do not all compete for the same segments of the market, and that increasing stringency in the standards can be expected to have different effects not only on certain vehicle segments but also on certain manufacturers that have developed market strategies around those vehicle segments, EPA concludes that the previous standards are not reasonable or appropriate.

Commented [A6]: This seems cursory.

In the initial determination, EPA assessed several factors related to consumer choice, including the costs to consumers of new vehicles and fuel savings to consumers, as described above under Section VII.A.2.c. In 2017, EPA found that the previous standards would increase the upfront costs of vehicles but overall would have positive net benefits because lifetime fuel savings outweighed the lifetime vehicle costs for consumers. As discussed above, the costs of technology to comply with the standards are generally borne by the initial purchaser, with understanding of fuel cost implication given statutorily required disclosures. In contrast, the fuel savings are realized by many subsequent owners over the vehicles' lifetime, which this analysis assumes can be up to 39 years. New vehicle purchasers are not likely to place as much weight on fuel savings that will be realized by subsequent owners. Accordingly, EPA is placing greater weight on the up-front vehicle cost savings to consumers in light of the goal of accelerating the turnover of the motor vehicle fleet to safer cars that emit fewer criteria pollutants.

Commented [A7]: This is confusing as written.

Commented [A8]: Why? Needs more analysis.

EPA received many comments regarding the agency's consideration of consumer choice in determining appropriate standards under section 202(a) of the CAA. The Alliance commented that EPA's concerns regarding consumer choice are well founded, stating "in the years since 2012 (and in part due to the unexpected decrease in fuel prices), consumers have demonstrated less interest in high-efficiency/low-emission vehicles than EPA and NHTSA projected in issuing the 2012 Final Rule. As such, compliance with the existing standards would require a substantially greater variance than EPA expected from the vehicle fleet that consumers would otherwise choose."

Global Automakers agreed that consumer acceptance is an important factor, but does not justify holding standards flat through the 2026 model year. Global Automakers further commented that "[f]uel economy remains a factor in vehicle purchase decisions, though perhaps not a dominant one."

CBD and others commented that the Clean Air Act does not allow EPA to reduce stringency based upon consumer choice factors. They point to the diversity of the vehicle fleet and argue that EPA's consideration of projected tech levels and associated costs as "speculative" and not grounded in fact.

U.S. Congressman Mark DeSaulnier claimed that the justification for the proposal appeared to be consumer willingness to buy new vehicles. He claimed that absent any standards

whatsoever, automakers could produce more vehicles that consumers would want to purchase. He stated that the standards require all vehicles to become more efficient and that EPA has an overly simplistic understanding of American consumers, who, according to him, are “wary of the price tag” when shopping, but, nonetheless, “overwhelmingly want more efficient vehicles, and they want to reduce the health burden of air pollution.”

The Institute for Policy Integrity (IPI) claims, without support, that as fuel efficiency technology is introduced and becomes widespread, consumer attitudes will change and will start focusing on such technology. IPI also claims that manufacturers can change consumer preference through advertising. IPI implies that manufacturers play a larger role in shaping consumer options of their needs than consumers do themselves. IPI also comments that academic literature relating to demand- and supply-side obstacles to fuel economy indicates that the proposal’s justification runs counter to available evidence.

The University of California Berkeley Environmental Law Clinic (Berkeley) argued against EPA’s consideration of consumer choice in setting standards, claiming that low-income households bear exposure to operating costs, fuel price fluctuations, and environmental impacts. Berkeley also claimed that EPA’s purported list of features consumers may favor over fuel economy is not supported by evidence, and, in any event, should be categorized into lists of “needs” versus “wants.”

Consumer choice is a complex consideration when setting standards. As Congressman DeSaulnier correctly notes, EPA cannot disregard its consideration of public health and welfare based upon the agency-projected whims of consumers. At the same time, the willingness of consumers to pay for fuel economy improvements, which as described above affects vehicle performance and utility in a manner distinguishable from criteria pollutant emissions, has a direct effect upon the ability of manufacturers to sell their product. And as consumers demand vehicles with increased ride height (which, all else being equal, increases CO₂ emissions), establishing standards that account for this—but still require manufacturers to focus on improving emission performance, is reasonable and appropriate.

In response to Global Automakers’ comment that consumers do not heavily focus on fuel economy in making purchase decisions, EPA agrees, but notes that this is a consumer’s choice, as federal law requires that consumers are made aware of fuel economy impacts, as further described in [Section XXX]. EPA also agrees that the willingness to pay for fuel economy improvements is “not zero.”

EPA agrees with the Global Automakers comment that while consumer choice is an important consideration in determining the appropriate level of the revised standards, the final rule analysis does not support holding the standards constant. Although EPA proposed standards at the level of 0 percent increase in stringency from MY 2021 and later, after considering the comments received and based on the updated analysis for this final rule, EPA is finalizing standards with a 1.5 percent per year improvement in stringency from MY 2021 to MY 2026.

As indicated in the comments on this topic, there is a range of views and relevant information concerning the extent of consumers' interest in fuel economy and on the role fuel savings plays in consumer purchase decisions.²⁴⁴¹ EPA's understanding is that some consumers value fuel economy more than others, and EPA finds it unnecessary to identify the precise role of fuel economy in consumer purchase decisions because the Administrator believes that the standards should encourage a range of vehicles meeting a range of consumer preferences. Further, as described above, consumers are made aware of the relative fuel price impacts of new vehicles, given the required information label on new vehicles, thus indicating that, in all likelihood, consumers do take fuel expenses into account when making new vehicle purchase decisions.

EPA disagrees with Congressman DeSaulnier's assertion that EPA seeks to set standards that do not affect what manufacturers produce—instead, the agencies examine what consumers are purchasing in the market to determine what standards are appropriate. The agency's assumptions in 2012—that consumers would gravitate toward the purchase of compact sedans and coupes in response to exceedingly high fuel prices—have proved incorrect. Fuel prices have fallen and remained relatively low, and are projected to remain relatively low throughout the period covered by this rulemaking. EPA seeks to achieve improvements in CO₂ emissions, but it is not realistic to expect the high demand for crossover vehicles to abate, or for those vehicles to meet more-stringent standards set for compact sedans. That said, EPA agrees with Congressman DeSaulnier that American consumers are wary of the price of vehicles—popular reporting that consumers may reference explain affordability concerns in crisis terms—even indicating that the average price of a vehicle is now beyond that which is affordable to the median household income of every city outside of Washington, D.C.²⁴⁴² This results in significant adverse economic impacts—higher finance charges, taxes, registration fees, and insurance costs, all of which result in challenges qualifying for financing and longer finance terms, which increase the likelihood of negative equity scenarios. EPA also agrees with Congressman DeSaulnier that consumers want increased fuel efficiency and to reduce the impacts of harmful air pollution. These are all true. But direct health impacts of vehicles emissions stem more from criteria pollutant emissions than from CO₂ emissions. And CO₂ emission technology has a significant relationship to the price of vehicles for which consumers are so wary. EPA, with this rulemaking, is attempting to strike the correct balance between a number of factors, including

²⁴⁴¹ Studies of the role of fuel economy in consumer purchase decisions have found a wide range of values (Greene, D., A. Hossain, J. Hofmann, G. Helfand, and R. Beach. "Consumer Willingness to Pay for Vehicle Attributes: What Do We Know?" *Transportation Research Part A* 118 (2018), p. 258-79.). The National Academy of Sciences in 2015 judged that "there is a good deal of evidence that the market appears to undervalue fuel economy relative to its expected present value, but recent work suggests that there could be many reasons underlying this, and that it may not be true for all consumers." National Research Council of the National Academies (2015). *Cost, Effectiveness, and Deployment of Fuel Economy Technologies for Light-Duty Vehicles*. Washington, DC: National Academies Press, p. 9-16.

²⁴⁴² See, e.g., Car and Driver, "For Middle-Class Shoppers, New Cars Are Moving out of Reach" November 30, 2019. Available at: <https://www.caranddriver.com/news/a30061910/middle-class-car-shoppers-priced-out/>; New York Times, "New Cars Are Too Expensive for the Typical Family, Study Finds" July 2, 2016. Available at: <https://www.nytimes.com/2016/07/02/your-money/new-cars-are-too-expensive-for-the-typical-family-study-finds.html>.

improving efficiency and affordability, which should yield additional sales and an improved rate of fleet turnover to vehicles that have better criteria pollutant emissions—particularly since the vehicles sold subject to this rulemaking will be sold during the phase-in of Tier 3 criteria pollutant emission standards.

In response to Berkeley, low-income consumers are even more sensitive to upfront vehicle purchase prices than they are to the smaller delta between weekly or monthly fuel costs experienced over time between the previous standards and the standards finalized today—they may well take note of the fact that one cannot pay today's bills with tomorrow's savings. They may also want to take note that the standards finalized today are projected to improve fleet turnover into newer vehicles that emit reduced criteria pollutants.

EPA disagrees with the assertion by CBD and others that the agency has not provided a rationale for its consideration of consumer choice in determining the appropriate standards. EPA notes that despite a variety of vehicles on the market today and over the past several years, the fleet has failed to comply with standards based upon performance beginning with the 2016 model year, and has fallen further behind in the 2017 model year, when only three major automakers complied with CO₂ emission standards based upon performance alone.

In response to IPI's comment that the deployment of more fuel-efficient technologies, combined with manufacturer advertising, will change consumer preference, this runs counter to historical trends. Manufacturers have continuously deployed additional fuel efficiency technology in each model year—which is why EPA continues to see fleetwide improvements in CO₂ emissions on new vehicles. And manufacturers have consistently advertised the fuel economy performance of their vehicles. Federal law requires the physical posting fuel economy performance, as well as estimated and comparative fuel cost information, on every new vehicle offered for sale. Notwithstanding this activity, consumer demand, and willingness to pay for technology that reduces CO₂ emissions and improves fuel economy, has not matched required standards—which is one of the reasons that EPA is revising the standards today. As discussed in the proposal, EPA recognizes that the diversity in the automotive customer base, combined with the facts and analysis developed by the agency in this rulemaking, raises concerns that the previous standards, if they are not adjusted, may not continue to fulfill the agency's goal of providing sufficient manufacturer flexibility to meet consumer needs and consumer choice preferences in their vehicle purchasing decisions. In the 2012 Final Rule and the Initial Determination, EPA expected that consumers would readily accept fuel-saving technologies in their new vehicles, despite the agency's uncertainty about the role of fuel savings in consumers' purchase decisions. Given low fuel prices and the pronounced market shift to crossovers and SUVs, notwithstanding required disclosures of fuel costs and relative fuel economy performance, EPA now concludes that it is appropriate to account for the shift in consumer preference in concluding that the standards set in 2012 did not provide sufficient lead time for manufacturers to achieve the standards set at that time. EPA remains concerned that the projected level of hybridization and other advanced technologies and the associated vehicle costs necessary to achieve the previous standards are too high from a consumer-choice perspective, and not sufficiently account for consumer acceptance of such technology. While consumers have benefited from improvements over several decades in traditional vehicle technologies, such as advancements in transmissions and internal

Commented [A9]: Why?

Commented [A10]: This seems to conflate different concepts. Isn't lead time a distinct rationale from consumer preference and fuel prices?

combustion engines, electrification technologies are a departure from what consumers have traditionally purchased. Strong hybrid and other advanced electrification technologies have been available for many years (20 years for strong hybrids and eight years for plug-in and all electric vehicles), and sales levels have been relatively low, in the 2-3 percent range.²⁴⁴³ As discussed above, the analysis projects that the 2012 EPA standards would be projected to require a significant increase in hybridization (up to 8 percent for mild hybrids and 10 percent for strong hybrids in MY 2030). This large increase in technology demand over the next decade could lead to automotive companies needing to change the choice of vehicle types they are able to offer to consumers, compared to what the companies would otherwise have offered in the absence of the previously issued standards. As discussed above, manufacturers are, by and large, not meeting existing standards based upon actual fleet performance in CO₂ emissions and are instead relying upon the use of earned or acquired credits. As the previous standards were set to increase significantly through MY 2020 and thereafter, reducing the rate of increase is appropriate and reasonable. Doing so will provide manufacturers with sufficient lead time to meet the standards being set today.

EPA recognizes that one possibility for automotive companies who wish to retain their current vehicle offerings, but face compliance challenges is to purchase GHG emissions credits. In EPA's annual Automotive Trends Report, EPA has reported that credit trading has occurred frequently in the past several years to achieve compliance with the GHG standards.²⁴⁴⁴ Credit trading can lower a manufacturer's costs of compliance, both for those selling and those purchasing credits, and this program compliance flexibility is another tool available to auto firms to allow them to continue offering the types of vehicles that customers want. Between MY 2010 and MY 2017, these trades have included 11 firms, with five firms selling CO₂ credits to seven firms.²⁴⁴⁵ The number of firms participating in the GHG credits market represents about one-half of the automotive companies selling vehicles in the U.S. market, but since several of these firms are small players, they represent less than half of the vehicle production volume. In total, approximately 48 million Megagrams of CO₂ credits have been traded between firms, which represents 19 percent of the MY 2017 industry-wide bank of credits. That said, more manufacturers have relied upon previously earned credits to achieve compliance. Between MY 2010 and MY 2017, [XX percent/#] of firms applied previously earned credits. However, long-term planning is an important consideration for automakers, and an automaker who may need to purchase credits as part of a future compliance strategy is not guaranteed to find credits. The automotive industry is highly competitive, and firms may be reluctant to base their future product strategy on an uncertain future credit availability, but face struggles in achieving CO₂ emission reductions in a manner that meets consumer expectations for cost, utility, and

²⁴⁴³ For instance, the 2019 calendar year saw only a 1.4% penetration of battery electric vehicles in the light duty fleet, following 1.2% for 2018, 0.6% for 2017, 0.5% for 2016, and 0.4% for 2015. [Wards Auto]

²⁴⁴⁴ 2018 EPA Automotive Trends Report at Figures 5.15 and 5.17.

²⁴⁴⁵ EPA Greenhouse Gas Emission Standards for Light-Duty Vehicles: Manufacturer Performance Report for the 2016 Model Year. EPA-420-R-18-002. January 2019.

performance. Also, pools of available credits continue to decline over time as the standards become more stringent and previously banked credits are either used or expire; indeed, this has happened in recent years.²⁴⁴⁶ EPA's views on the availability of the credit market to aid in manufacturers' compliance have changed since the Initial Determination. Based upon the information available to the EPA in early January 2017, the auto industry had outperformed its standards in the four previous compliance years (MYs 2012-2015) and EPA had viewed that as a positive trend.²⁴⁴⁷ Since then, however, overall manufacturer performance failed to meet the standard fleetwide, and many manufacturers relied on credits to meet their individual compliance targets. Furthermore, recent experience suggests that availability of the credit bank is becoming a more uncertain means to achieve compliance.²⁴⁴⁸ Thus, while credit trading may be a useful flexibility to reduce the overall costs of the program and to smooth the pathway to compliance realizing necessary transitions from vehicle redesign cycles, EPA believes it is important to set standards that preserve consumer choice without relying on credit purchasing availability as a compliance mechanism. As discussed in [Section VII], the agencies project that the EPA final standards (Alternative 3, 1.5 percent year over year stringency improvement), will require more realistic penetration of advanced CO₂ emission technologies such as electrification—better ensuring that manufacturers will be able to provide vehicles that meet consumer demand.

f) Consideration of Safety

As discussed above, EPA has long considered the safety implications of its emission standards.²⁴⁴⁹ More recently, EPA has considered the potential impacts of emission standards on safety in past rulemakings on GHG standards, including the 2010 rule which established the 2012-2016 light-duty vehicle GHG standards, and the 2012 rule which previously established 2017-2025 light-duty vehicle GHG standards. Indeed, section 202(a)(4)(A) specifically prohibits the use of an emission control device, system or element of design that will cause or contribute to an unreasonable risk to public health, welfare, or safety.²⁴⁵⁰ The relationship between CO₂ emissions and safety is more nuanced. Safety impacts relate to changes in the use of vehicles in the fleet, relative mass changes, and the turnover of fleet to newer and safer vehicles.

The analysis for the final rule projects that there will be a change in vehicle miles traveled (VMT) under the final standards, specifically 607 billion less miles traveled compared to the previous standards case. Based on these projections about reduced VMT in the light-duty fleet, the analysis estimates that fatalities will be reduced by [X] over the lifetime of MY 1977-

²⁴⁴⁶ 2018 EPA Automotive Trends Report at Figure 5.17 and Table 5.17.

²⁴⁴⁸ Id. at Figure ES-8.

²⁴⁴⁹ See, e.g., 45 FR 14496, 14503 (1980) ("EPA would not require a particulate control technology that was known to involve serious safety problems.").

²⁴⁵⁰ 42 U.S.C. 7521(a)(4)(A).

2029 vehicles compared to the previous CO₂ standards.²⁴⁵¹ In other words, the reduction in fatalities under the final standards compared to the previous standards is primarily driven by the modeling's projected changes in VMT and associated changes in mobility (i.e., people driving less). The details of the safety assessment are discussed in [Section X] of this preamble and in [Chapter X] of the FRIA. Under alternatives with stringency levels lower than the final standards, the analysis projects greater reductions in VMT, and thus projects somewhat greater reductions in fatalities based on these VMT changes. Under alternatives with stringency levels higher than the final standards, the analysis projects lower reductions in VMT, and thus projects fewer fatalities reduced [See Table X].

Commented [A11]: Awkward phrasing—fewer reduced.

EPA notes that the magnitude of the changes in fatalities stemming from changes in mobility projected in this final rule is less than what was presented in the proposed rule. In response to comments, the agencies took a conservative approach to modeling the effects of standard stringency upon safety. The agencies held VMT constant across alternatives. The reasons for the differences in fatality estimates in the final rule compared to the proposed rule, including changes to the modeling inputs and projections based on the agencies' assessment of public comments, are explained elsewhere in this preamble (see section xx).

The approach for reporting fatality impacts for this final rule is different than the previous analyses for the Initial Determination and the 2012 rulemaking. First, the analysis quantifies the number of fatalities caused by changes in VMT between each Alternative and the previous standards, whereas previous analyses did not. Second, the safety analysis itself is different from previous analyses that assumed that automakers would not reduce the weight of approximately the lightest half of passenger cars—discounting the safety impacts of mass reduction. Third, while the agencies qualitatively discussed the effect of price increases attributable to increased stringency on vehicle sales, fleet turnover, and the improved safety of newer vehicles, the agencies never attempted to quantify these impacts.

With respect to public comments, the Alliance commented that "EPA has discretion to consider all the relevant factors in setting appropriate emissions standards under §202(a)(1), including vehicle safety. Moreover, given NHTSA's greater expertise in evaluating motor vehicle safety, it is appropriate for EPA to respect the views of its companion agency on those issues." The Alliance commented that "[t]he new safety analysis likewise provides support for EPA's conclusion that the MY 2021–2025 GHG standards are not appropriate and should be reduced in stringency. Indeed, given that the 'primary purpose' of §202(a)(1) is 'the protection of public health and welfare,' EPA would be abdicating its statutory duty if it ignored these concerns."

²⁴⁵¹ The number of fatalities projected is a product of two contributing factors: the number of miles driven (VMT) and the risk of driving (i.e., fatalities per mile). Overall in this final rule analysis, the change in fatalities projected is primarily caused by the changes in VMT.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Global Automakers commented that safety impacts due to the rebound effect should not be attributed to the standards and should not serve as a basis for keeping the standards flat. They further argued that the dynamic scrappage model is flawed and should be removed from the modeling for purposes of the final rule. They also argued, that Congress expressed interest in improving efficiency, emissions, and safety (without no recognition of cost as a factor), and that therefore, improvement in all such areas should provide that improvements in efficiency would not lead to negative safety impacts.

CBD and others commented that safety concerns should not be considered because the record does not indicate that vehicles must be unsafe to meet the previous standards. They further commented that EPA cannot justify reduced stringency upon “rebound” fatalities, and they argue that those fatalities cannot be considered by EPA, since they “stem from voluntary choices by individuals to drive more—not the ‘operation or function’ of the technologies at issue” (quoting CAA Section 202(a)(4)(A)).

Environmental Defense Fund (EDF) similarly commented that the estimates of fatalities are unsound, as is considering total fatalities resulting from increased stringency, rather than fatality rates. They added that the projected fatalities stem from consumer and manufacture behaviors that are removed from the stringency requirements. They further argue that considering fatalities that are attributable to the standards—particularly rebound fatalities—are inappropriate. EDF, UCS, and Consumers Union argue that fatalities attributable to increased driving are not relevant to agency decisions.

In response to the Alliance comments, EPA has considered safety, as described in this section, and agrees that the potential impacts of emission standards on safety is an important consideration in determining appropriate standards under CAA section 202(a). In response to comments from Global Automakers that the safety analysis in the proposed rule did not support freezing the standards, EPA agrees that safety considerations alone do not justify such an approach, and notes that the safety analysis performed for this final rule has changed from the analysis for the proposed rule based on consideration of public comments. EPA is finalizing standards that are more stringent (1.5 percent per year stringency improvement for MY 2021-2026) than the proposed rule’s preferred alternative (0 percent stringency improvement).

Several commenters argued that the proposal’s claims of reduced fatalities were based upon projected changes in driving, arguing that that EPA should not decide the level of the standards based on these assumed changes in travel. As discussed above, EPA acknowledged that the reduction in fatalities under the final standards compared to the previous standards are in large part driven by projected changes in driving behavior (i.e., people driving less). While EPA is not seeking to restrict mobility or driving, ignoring impacts associated with this rule would be inappropriate. Moreover, the provisions of Section 202(a)(4) do not preclude EPA from considering such impacts. While EPA has considered the safety assessment for this final rule, as discussed in the following section below, safety was one of several factors considered in deciding on the level of today’s final standards.

g) *Consideration of Energy Security Impacts*

Among other factors EPA considered in selecting the previous standards in the 2012 Final Rule was the effect of the standards on U.S. petroleum imports and energy security.²⁴⁵² As discussed in the PRIA, [final RIA] and in Section [X], the energy security position of the United States has changed dramatically since 2012. The U.S. has become a net *exporter* of petroleum and additional payments by United States consumers resulting from upward pressure on oil price due to additional demand are a transfer that occurs *within* the United States economy.²⁴⁵³ Additional petroleum use necessarily increases demand and thus subjects the nation to additional risk of price shocks, but this risk is significantly reduced as the United States has dramatically increased domestic petroleum production and has additional capacity to do so. Accordingly, energy security concerns are reduced compared to the assessment in the 2012 rulemaking and do not alter EPA's selection of final revised standards in this rule.

h) *Balancing of Factors and EPA's Revised Standards for MY 2021 and later*

As discussed in this section, the Administrator is required to consider a number of factors when establishing emission standards under section 202(a)(2) of the Clean Air Act: the standards "shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."²⁴⁵⁴ For this Final Rule, the Administrator has considered a wide range of potential emission standards (Baseline/No Action Alternative and Alternatives 1 through 7), ranging from the previous EPA standards (Baseline/No Action Alternative), through a number of less stringent alternatives, including the proposed preferred alternative (Alternative 1, 0 percent per year stringency improvement) and what has been chosen as the final standards (Alternative 3, 1.5 percent per year stringency improvement). The Administrator has determined that the revised final standards, which would increase the stringency of the MY 2020 standards by 1.5 percent per year for both passenger cars and light-trucks from MY 2021 through 2026, are appropriate under section 202(a) of the CAA. In addition to technological feasibility, lead-time, and the costs of compliance, the Administrator has also considered the impact of the standards on GHG and non-GHG emissions reductions, the costs to consumers, and vehicle safety.

²⁴⁵² See 77 FR 62938, *et seq.*

²⁴⁵³ The U.S. Energy Information Administration EIA estimates that the United States exported more total crude oil and petroleum products in September and October 2019, and expects the United States to continue to be a net exporter. See *Short Term Energy Outlook November 2019*, available at <https://www.eia.gov/outlooks/steo/archives/nov19.pdf>.

²⁴⁵⁴ 42 U.S.C. 7521(a)(2).

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

In addition to comments on each of the factors the Administrator considered discussed above, comments also were received on how the Administrator should balance these factors in determining the appropriate final standards.

The Alliance commented that the CAA provides EPA with significant latitude to exercise its expert judgment in determining the level at which emissions standards should be set. The Alliance commented further that unlike other CAA provisions, §202(a)(1) does not require EPA to set standards that will result in the greatest degree of emission reduction achievable. Instead, the statute leaves EPA flexibility to decide what factors are relevant, and how to weigh those factors, in its decision-making process. The Alliance also commented “EPA also has ‘significant latitude’ regarding the ‘coordination of its regulations with those of other agencies,’” “EPA has discretion to defer to the judgment of other agencies regarding issues within their areas of expertise,” and the CAA “gives the agency authority to engage in reasoned decision-making, balancing all of the relevant factors in light of the available facts. EPA has done that here and has provided a reasoned explanation of its determination that the environmental benefits of the existing MY 2021-2025 GHG standards are outweighed by their negative effects on costs and safety.”

The American Iron and Steel Institute commented that it favors the general direction taken in the SAFE proposal, including the preferred option for CO₂ standards, and that it believes a final SAFE rule that “balances the priorities of costs to consumers, safety design considerations, employment impacts and total GHG emissions will result in the best outcome.”

CBD and others claimed that the justifications EPA offered in the notice are untethered from the statute, and that EPA used a flawed analysis. Further, they claim that EPA did not exercise its own judgment and delegated its responsibilities impermissibly to NHTSA, failing to consider “relevant EPA information.”

EPA’s analysis is described in detail in this preamble. EPA decided to use the CAFE model for a number of reasons, described in more detail in [Section X], including that using two models results in an inefficient use of resources, the CAFE model can analyze both EPA’s and NHTSA’s statutory programs, the CAFE model is capable of modeling incremental improvements of discrete technologies, and EPA believes that the CAFE model provides reasonable results. Merely because EPA has a set of its own analytical tools that model similar effects does not mean that it must use those tools to perform the analysis, and doing so would create unnecessary complication and lead to potential inconsistencies. Since the agencies are establishing standards jointly and seeking to avoid inconsistencies in a manner consistent with Supreme Court direction, using the same model for the analysis is reasonable. Nonetheless, EPA has exercised its own judgment in this final rule.

The California Attorney General and others claim that EPA failed adequately to acknowledge, explain, or justify its departure from the prior determination. They claim that EPA failed to propose or make a finding required by Section 202(a)(2) relating to adequate lead time, inconsistent with EPA’s prior explanation that it is provided with limited flexibility in making such a determination.

Commented [A12]: This is too cursory. Does not adequately meet the substance of the comments or support the Final Rule.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

The California Attorney General and others also claim that EPA’s analysis improperly weighs the factors it considers, and that it insufficiently weighed certain factors required under the Clean Air Act, including air pollution. In response, EPA notes that the Clean Air Act does not specify how the Administrator should weigh the factors considered, as discussed elsewhere in this section.

The California Attorney General and others further noted that the purpose of the Clean Air Act is to “protect and enhance the quality of the Nation’s air resources so as to promote the public health and welfare and the productive capacity of its population.”

The Institute for Policy Integrity claimed that the agencies balanced the factors in a way that conflicts with their controlling statutes and weighed the statutory factors without regard for the accuracy of the accompanying cost-benefit analysis.

The National Coalition for Advanced Transportation claimed that the proposal appeared to be based on heightened concerns with cost, consumer acceptance, and safety, and insufficiently on technology availability and emissions reductions. As discussed in this section, EPA is neither relying solely on cost or safety nor ignoring any factors, but rather is balancing a number of factors.

Green Energy Institute at Lewis and Clark Law School et al. commented that the Clean Air Act does not authorize the weakening or freezing of existing standards due to industry costs or consumer preferences. While EPA has broad discretion to revise standards based upon a balancing of factors, the final rule will provide for increasing stringency of 1.5 percent per year from MY 2021 through MY 2026.

Motor & Equipment Manufacturers Association (MEMA) commented that the technology costs from their preferred alternative (Alternative 8 in the notice) were not significant and did not justify holding MY 2020 standards flat in light of other elements, such as preserving investments in fuel saving technology. EPA disagrees, and considers the reductions in costs resulting from the revised final standards, \$1,063 per vehicle by MY 2029, to be one important aspect of the justification of these standards.

EPA believes the previously issued standards for MY 2021 and later, considered as a whole, are too stringent. Factors in favor of reduced stringency include manufacturer compliance costs, and the related per-vehicle cost savings. As described above, the agencies project that the final standards will reduce manufacturers’ compliance costs by \$107 billion for the MY 2018-MY 2029 vehicles, which includes a per vehicle cost reduction of \$1,063 on average for the MY 2029 vehicles. Including other costs, such as financing and insurance, consumers the standards finalized today will result in reduced costs of \$1,385 per-vehicle for a MY 2029 vehicle. EPA expects that the final standards will not impede consumers from being able to purchase a new vehicle of their choice. In fact, under the final standards, vehicle sales are expected to increase by 2.2 million vehicles over MY 2017-2029 compared to projected sales under the previous standards, a significant increase in vehicles sold over this timeframe [see X].

EPA views this projection of vehicle sales increases resulting from the final standards as important in facilitating the turnover of the fleet to newer, safer vehicles, all of which will be subject to increasingly stringent criteria pollutant emission requirements as federal Tier 3 emission standards continue to phase in from MY 2017 through MY 2025.

Another factor weighing toward reduced stringency is safety. As discussed previously, reduced stringency results in less pressure on manufacturers to reduce mass in vehicles, which, for smaller passenger cars has negative safety implications when involved in accidents with heavier vehicles. Further, as vehicle prices decrease compared to the previous standards, more consumers will be able to afford newer vehicles, which are significantly safer. Lastly, as vehicles will not be required to be as fuel efficient as under the previous standards, “rebound” driving will be reduced. The agencies project a reduction in 607 billion miles traveled in the light-duty fleet with a corresponding reduction in 3,125 fatalities under the final standards compared to the previous standards (i.e., people are projected to drive less under the final standards with an associated reduction in driving-related fatalities). While the Administrator does not seek to change the way people drive—EPA’s intention is not to restrict mobility, or to discourage driving, based on the level of the standards—EPA nonetheless believes it is appropriate to consider this projection.

Factors that weigh in favor of increased stringency options are increased upstream criteria pollutant emissions attributable to additional refining and other fuel-related activities, as well as increased CO₂ emissions and consumer fuel expenditures.

As described above, the agencies project that the revised final standards will have a negative impact on air quality health outcomes, including a projected increase of 440 to 990 premature deaths from increased air pollution over the lifetime of the MY 1977-2029 vehicles on the road after calendar year 2017. EPA recognizes that the final standards are projected to increase CO₂ emissions compared to the previous EPA standards. However, EPA notes that, unlike other provisions in Title II referenced above, section 202(a) does not require EPA to set standards for light-duty vehicles which result in the “greatest degree of emission reduction achievable.” EPA further notes that the agency decided against pursuing more stringent alternatives analyzed in both the rulemaking establishing 2012-2016 standards and the rulemaking establishing 2017-2025 standards.

EPA has also given weight to the policy goal of establishing CO₂ standards which are coordinated with NHTSA’s CAFE standards. While not a statutory requirement, EPA has considered the importance of having coordinated and harmonized EPA CO₂ and CAFE programs, while recognizing the different statutory authorities for those programs, since the establishment of the EPA CO₂ program. The agencies discussed the importance of having one national program in the SAFE Vehicles Part 1 joint action.²⁴⁵⁵ In today’s joint final rule, DOT is establishing CAFE standards for MY 2021-2026 which increase in stringency at a level of 1.5

²⁴⁵⁵ 84 FR 51,310 (Sept. 27, 2019).

percent per year. The revised EPA standards will also increase in stringency at a rate of 1.5 percent per year. Coordinating revisions to the GHG and CAFE standards in order to maintain one national program is a factor the Administrator has consideration in determining the revised GHG standards.

Commented [A13]: Needs more analysis and explanation.

In light of available statutory discretion and the range of factors that the statute authorizes and permits the Administrator to consider, and his consideration of the factors discussed above, the EPA concludes that reducing the stringency of the MY 2021-2026 standards is an appropriate approach under section 202(a). Therefore, based on the data and analysis detailed in this final rule, the Administrator concludes that the previous MY 2021 and later CO₂ standards are too stringent, and is establishing revised standards for MY 2021 through MY 2026 at a level of 1.5 percent per year improvement in stringency.

Commented [A14]: Need more explanation of why 1.5 is the right number.

In response to comments concerned about EPA's proposal to freeze the MY 2021-2026 standards at MY 2020 levels, EPA notes that it is finalizing the 1.5 percent per year improvement in stringency level and not the 0 percent improvement level proposed, after considering the somewhat higher costs to industry and up-front vehicle costs to the consumer and slightly lower GHG emissions and health-related impacts compared to the proposed preferred alternative. The Administrator has taken these tradeoffs into account in his balancing of factors under section 202(a) of the CAA.

Commented [A15]: More explanation?

While the set of factors considered by EPA under section 202(a) of the CAA in today's final rule and under the midterm evaluation regulations²⁴⁵⁶ in the Initial Determination are similar and overlapping, the Administrator recognizes that he is balancing these factors differently in this final rule than in the Initial Determination. In the Initial Determination, EPA's decision that the previous MY 2022-2025 standards were appropriate was based on conclusions that the standards were feasible within the lead time provided at reasonable costs, the standards would result in significant reductions in GHG emissions and oil consumption and associated fuel savings for consumers, and the standards would yield significant benefits to public health and welfare and positive net benefits overall, without adverse impacts on industry, safety, or consumers.²⁴⁵⁷

Since the Initial Determination, EPA has completed its compliance review of the first two model years covered by the 2012 final rule. Notwithstanding widespread availability of vehicles that meet or exceed their CO₂ emission targets, consumers are not expressing sufficient interest in fuel economy in their purchasing decisions to enable manufacturers to meet the standards based upon fleet performance. Although manufacturers earned significant credits in the early years of the agency's CO₂ regulation history, these credits are being applied at a rate that is higher than the agency expected, and well in advance of the more aggressive model year stringency increases. While some alternative fuel automakers are earning significant tradable

²⁴⁵⁶ 40 CFR 86.1818-12(h).

²⁴⁵⁷ Initial Determination, Section III Th, page 29-30.

credits, they do not have to trade them. And building a program around the potential for acquiring credits from competing manufacturers is unsustainable. While EPA is analyzing the differences between these standards and the previous standards for this rulemaking, EPA cannot ignore that this rulemaking was foreseen in the 2012 rulemaking. The prospect of revising the standards was expressly envisioned in that rulemaking based upon the uncertainty in the assumptions and future projections at that time. When viewed from the perspective of the larger set of MY 2017 through MY 2026 standards rulemakings, the standards finalized today fit the pattern of gradual, tough, but feasible stringency increases that take into account real world performance, shifts in fuel prices, and changes in consumer behavior toward crossovers and SUVs and away from more efficient sedans. This approach ensures that manufacturers are provided with sufficient lead time to achieve standards, considering the cost of compliance.

Commented [A16]: This reads more like a summary of an analysis than an actual analysis. This needs a deeper dive.

In this final rule, the EPA is placing greater weight on the costs to industry and the up-front vehicle costs to consumers. EPA believes that the costs to both industry and automotive consumers would have been too high under the previous standards, and that the standards should be revised to be less stringent to lower these costs. EPA believes that by lowering the auto industry's costs to comply with the program, with a commensurate reduction in per-vehicle costs to consumers, the final rule is enhancing the ability of the fleet to turn over to newer, cleaner and safer vehicles.

EPA believes that the characteristics and impacts of these and other alternative standards generally reflect a continuum in terms of technical feasibility, cost, lead time, consumer impacts, emissions reductions, and oil savings, and other factors evaluated under section 202(a). In determining the appropriate standard to adopt in this context, EPA judges that the final standards are appropriate and preferable to more stringent alternatives based largely on consideration of cost—both to manufacturers and to consumers—and the potential for overly aggressive penetration rates for advanced technologies relative to the penetration rates seen in the final standards, especially in the face of an unknown degree of consumer acceptance of both the increased costs and of the technologies themselves—particularly given current projections of fuel prices during that timeframe. At the same time, the final rule helps to address these issues by maintaining incentives to promote broader deployment of advanced technologies, and so provides a means of encouraging their further penetration while leaving manufacturers alternative technology choices. EPA thus judges that more stringent alternatives, which would necessitate even more technology and more cost, would not be appropriate.

B. NHTSA’s statutory obligations and why the selected standards are maximum feasible as determined by the Secretary

1. EPCA, as amended by EISA

EPCA, as amended by EISA, contains a number of provisions regarding how to set CAFE standards. DOT (by delegation, NHTSA)²⁴⁵⁸ must establish separate CAFE standards for passenger cars and light trucks²⁴⁵⁹ for each model year,²⁴⁶⁰ and each standard must be the maximum feasible that the Secretary (again, by delegation, NHTSA) believes the manufacturers can achieve in that model year.²⁴⁶¹ In determining the maximum feasible level achievable by the manufacturers, EPCA requires that NHTSA consider four statutory factors of technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy.²⁴⁶² In addition, NHTSA has the authority to consider (and traditionally does) other relevant factors, such as the effect of the CAFE standards on motor vehicle safety and consumer preferences.²⁴⁶³ The ultimate determination of what standards can be considered maximum feasible involves a weighing and balancing of factors, and the balance may shift depending on the information before NHTSA about the expected circumstances in the model years covered by the rulemaking. The agency’s decision must also support the overarching purpose of EPCA, energy conservation, while balancing these factors.²⁴⁶⁴

Besides the requirement that the standards be maximum feasible for the fleet in question and the model year in question, EPCA/EISA also contain several other requirements, as explained below.

a) *Lead time*

EPCA requires that NHTSA prescribe new CAFE standards at least 18 months before the beginning of each model year.²⁴⁶⁵ Thus, if the first year for which NHTSA is proposing to set

²⁴⁵⁸ EPCA and EISA direct the Secretary of Transportation to develop, implement, and enforce fuel economy standards (*see* 49 U.S.C. 32901 *et. seq.*), which authority the Secretary has delegated to NHTSA at 49 CFR 1.95(a).

²⁴⁵⁹ 49 U.S.C. 32902(b)(1) (2007).

²⁴⁶⁰ 49 U.S.C. 32902(a) (2007).

²⁴⁶¹ *Id.*

²⁴⁶² 49 U.S.C. 32902(f) (2007).

²⁴⁶³ Both of these additional considerations also can be considered part of economic practicability, but NHTSA also has the authority to consider them independently of that statutory factor.

²⁴⁶⁴ *Center for Biological Diversity v. NHTSA*, 538 F. 3d 1172, 1197 (9th Cir. 2008) (“Whatever method it uses, NHTSA cannot set fuel economy standards that are contrary to Congress’s purpose in enacting the EPCA – energy conservation.”).

²⁴⁶⁵ 49 U.S.C. 32902(a) (2007).

new standards in this NPRM is MY 2022, NHTSA interprets this provision as requiring the agency to issue a final rule covering MY 2022 standards no later than April 1, 2020.

For amendments to existing standards, EPCA requires that if the amendments make an average fuel economy standard more stringent, at least 18 months of lead time must be provided.²⁴⁶⁶ EPCA contains no lead time requirement to amend standards if the amendments make an average fuel economy standard less stringent. NHTSA therefore interprets EPCA as allowing amendments to reduce a standard's stringency up until the beginning of the model year in question. In the NPRM, NHTSA proposed to amend the standards for model year 2021. NHTSA explained that since the agency was proposing to reduce these standards, the action was not subject to a lead time requirement.

The States and Cities commenters argued that NHTSA had counted 18 months incorrectly, and that "18 months prior to September 1, 2021 is in fact March 1, 2020."²⁴⁶⁷ NHTSA agrees that 18 months prior to September 1 would be March 1 of the year prior; the statement in the NPRM that "NHTSA has consistently interpreted the "beginning of the model year" as September 1 of the CY prior" was a typographical error. As prior Federal Register notices indicate, NHTSA has in fact long interpreted the beginning of the model year for CAFE compliance purposes as *October* 1 of the CY prior.²⁴⁶⁸ Thus, counting backwards, 18 months prior to October 1 is properly identified as April 1, meaning that new standards for MY 2022 must be established by April 1, 2020.

With regard to the amendments to the MY 2021 standards, a coalition of environmental groups commented that NHTSA's legal construction of EPCA's lead time requirement as not applying to MY 2021 was "not...permissible," arguing that section 32902(g)(1) only permits amendments to existing CAFE standards that "meet[] the requirement of subsection (a) or (d) as appropriate," and that section 32902(a) requires fuel economy standards to be prescribed 18 months before the beginning of the model year.²⁴⁶⁹ The environmental group coalition therefore argued that the two identified provisions must be read together to compel all amendments to standards to be prescribed at least 18 months before a model year, and concluded that because it was impossible to finish a final rule 18 months before the start of MY 2021, that MY 2021 standards could not be amended.²⁴⁷⁰ The States and Cities group provided similar comments, arguing that NHTSA's interpretation of (g)(2) rendered the reference in (g)(1) to (a) "a nullity," and that the "as appropriate" language in (g)(1) referred to the determination of whether providing 18 months of lead time was appropriate, rather than to whether (a) or (d) was the

²⁴⁶⁶ 49 U.S.C. 32902(g)(2) (2007).

²⁴⁶⁷ States and Cities, NHTSA-2018-0067-11735, Detailed Comments, at 78, fn. 211.

²⁴⁶⁸ *See, e.g.*, 75 FR 25546 (May 7, 2010).

²⁴⁶⁹ Center for Biological Diversity, Conservation Law Foundation, Earthjustice, Environmental Defense Fund, Environmental Law and Policy Center, Natural Resources Defense Council, Public Citizen, Sierra Club, Union of Concerned Scientists (hereafter, "environmental group coalition"), Appendix A, NHTSA-2018-0067-12000, at 66.

²⁴⁷⁰ *Id.*

relevant provision governing the standards in question.²⁴⁷¹ NCAT commented that “Congress in § 32902 has indicated that at least 18 months of lead time are appropriate when setting standards,” and stated that “Manufacturers’ need for adequate lead time when designing products and developing compliance strategies is the same regardless of whether the agency is making standards more stringent, less stringent, or simply changing the structure or compliance options provided under the standards.”²⁴⁷² NADA, in contrast, argued that NHTSA does “have the authority and discretion to reopen the MY 2021 standards,” and that the “mandate for at least 18 months of lead time before new standards may take effect does not apply to instances, such as for MY 2021, where standards are being relaxed.”²⁴⁷³ CEI also agreed with NHTSA’s interpretation of lead time set forth in the NPRM.²⁴⁷⁴

NHTSA agrees that section 32902(g)(1) states that amendments must meet the requirements of subsection (a) or (d) as appropriate, and that 32902(a) states that standards must be prescribed 18 months in advance of the model year. However, NHTSA cannot agree that the 18-month lead time requirement applies to amendments to existing standards that reduce stringency. Section 32902(g)(2) clearly states that “[w]hen the Secretary of Transportation prescribes an amendment under this section that makes an average fuel economy standard *more stringent* (emphasis added), the Secretary shall prescribe the amendment ... at least 18 months before the beginning of the model year to which the amendment applies.” Commenters’ construction of the statute would render superfluous the words “more stringent” in 32902(g)(2), and there is a presumption against superfluity.²⁴⁷⁵ Congress purposely included the words “more stringent” in order to exclude the contrary situation—“less stringent”—from the 18-month lead time requirement. A plain reading of (g)(1) simply provides that the Secretary (by delegation, NHTSA) should refer to the correct provision depending on whether the standard being amended is generally applicable (pointing to section (a)) or a standard applicable to low-volume manufacturer pursuant to an exemption (pointing to section (d)). Reading (g)(1) and (g)(2) together is the appropriate way to give effect to both provisions. This reading provides that NHTSA may amend the MY 2021 standard by following the requirements for generally-applicable standards; this reading also provides that 18 months’ lead time is only required for amendments that *increase* stringency. NHTSA also does not agree that (g)(1) can be read to imply that the agency must provide 18 months of lead time “if appropriate,” as the States and Cities suggest, nor that there is any statutory basis to extend the lead time requirement to changes to the “structure or compliance options provided under the standards” as NCAT suggests. If new off-cycle technologies could not be recognized toward compliance without providing 18 months’ lead time, manufacturer efforts to rely on that compliance flexibility to redress past shortfalls would be frustrated.

²⁴⁷⁴ CEI, NHTSA-2018-0067-12015, at 3-4.

²⁴⁷⁵ See, e.g., *Duncan v. Walker*, 533 U.S. 167 (2001) (citing *U.S. v. Menasche*, 348 U.S. 528, 538-539 (1955)).

Moreover, automakers need more time to respond when NHTSA amends standards to be more stringent—doing so would likely require automakers to change their product and/or sales plans to ensure that they will meet more stringent standards than those standards for which they may have already prepared. But such product or sales plans would not necessarily *need* to be changed if standards were amended to be less stringent—in fact an automaker would be rewarded by keeping existing plans to comply in place with additional bankable and tradable overcompliance credits. However, the environmental group coalition argued that “[c]hanging the MY 2021 standard at this late date would penalize technologically advanced automakers and parts suppliers, who have already made significant investments in updating their technology.”²⁴⁷⁶ The States and Cities group made similar comments,²⁴⁷⁷ as did NCAT.²⁴⁷⁸ The environmental group coalition further suggested that amending the MY 2021 standard would reduce the need for (and thus the value) of overcompliance credits, “which would be disruptive to the manufacturers that have done the most to further EPCA’s conservation goals.”²⁴⁷⁹ NCAT made similar comments, arguing that “[t]he practical and financial impact of the change accordingly is not materially different from increasing the stringency of a standard this late in the product cycle.”²⁴⁸⁰

NHTSA believes that to the extent that some manufacturers have already invested in future fuel economy improvements, those manufacturers will continue to be well-positioned both to respond to increasing standards in the future, and to take advantage of any market demand for higher fuel economy/reduced tailpipe CO₂ emissions from consumers who put a premium on those aspects. NHTSA is also aware that several companies have self-imposed emissions-reduction goals which may drive their decisions on technology application regardless of regulatory obligations. NHTSA does not believe that companies which have already invested in higher levels of technology consider those investments to be bad ones. We note that manufacturer commenters, despite the concerns expressed by others, did *not* comment about a lack of lead time associated with changing the MY 2021 standards; rather, many manufacturer commenters expressly cited the need to revise MY 2021 standards, arguing that the previously-established values are beyond maximum feasible. Regarding the value of overcompliance credits under more or less stringent standards, NHTSA agrees that the need for credits may be less under less stringent standards, but this is true regardless of the lead time question. Further, NHTSA does not believe that this suggests only standards that compel reliance on overcompliance credits (especially those earned by competitors) can be maximum feasible; this topic will be addressed in further detail below, and regardless, NHTSA is prohibited from considering credit availability in determining maximum feasible CAFE standards.

b) Separate standards for cars and trucks, and minimum standards for domestic passenger cars

As discussed above, EPCA requires NHTSA to set separate CAFE standards for passenger cars and light trucks for each model year.²⁴⁸¹ NHTSA interprets this requirement as preventing the agency from setting a single combined CAFE standard for cars and trucks together, based on the plain language of the statute. Congress originally required separate CAFE standards for cars and trucks to reflect the different fuel economy capabilities of those different types of vehicles,²⁴⁸² and over the history of the CAFE program, has never revised this requirement. Even as many cars and trucks have come to resemble each other more closely over time—many crossover and sport-utility models, for example, come in versions today that may be subject to either the car standards or the truck standards depending on their characteristics—it is still accurate to say that vehicles with truck-like characteristics such as 4 wheel drive, cargo-carrying capability, etc., consume more fuel per mile than vehicles without these characteristics. Thus, NHTSA believes that the different fuel economy capabilities of cars and trucks would generally make separate standards appropriate for these different types of vehicles, regardless of the plain language of the statute which requires such treatment.

EPCA, as amended by EISA, also requires another separate standard to be set for domestically-manufactured²⁴⁸³ passenger cars. Unlike standards for passenger cars and light trucks described above, the compliance burden of the minimum domestic passenger car standard is the same for all manufacturers: the statute clearly states that any manufacturer’s domestically-manufactured passenger car fleet must meet the greater of either 27.5 mpg on average, or

92 percent of the average fuel economy projected by the Secretary for the combined domestic and non-domestic passenger automobile fleets manufactured for sale in the United States by all manufacturers in the model year, which projection shall be published in the Federal Register when the standard for that model year is promulgated in accordance with [49 U.S.C. 32902(b)].²⁴⁸⁴

Since that requirement was promulgated, the “92 percent” has always been greater than 27.5 mpg. NHTSA published the 92-percent minimum domestic passenger car standards for model years 2017-2025 at 49 CFR 531.5(d) as part of the 2012 final rule. For MYs 2022-2025,

²⁴⁸¹ 49 U.S.C. 32902(b)(1) (2007).

²⁴⁸² Indeed, EPCA initially only required NHTSA to establish CAFE standards for passenger cars; establishment of light truck standards was permissible.

²⁴⁸³ In the CAFE program, “domestically-manufactured” is defined by Congress in 49 U.S.C. 32904(b). The definition roughly provides that a passenger car is “domestically manufactured” as long as at least 75% of the cost to the manufacturer is attributable to value added in the United States, Canada, or Mexico, unless the assembly of the vehicle is completed in Canada or Mexico *and* the vehicle is imported into the United States more than 30 days after the end of the model year.

²⁴⁸⁴ 49 U.S.C. 32902(b)(4) (2007).

531.5(e) states that these were to be applied if, when actually proposing MY 2022 and subsequent standards, the previously identified standards for those years are deemed maximum feasible, but if NHTSA determines that the previously identified standards are not maximum feasible, the 92-percent minimum domestic passenger car standards would also change. This is consistent with the statutory language that the 92-percent standards must be determined at the time an overall passenger car standard is promulgated and published in the Federal Register. Thus, any time NHTSA establishes or changes a passenger car standard for a model year, the minimum domestic passenger car standard for that model year will also be evaluated or reevaluated and established accordingly. NHTSA explained this in the rulemaking to establish standards for MYs 2017 and beyond and received no comments.²⁴⁸⁵

The 2016 Alliance/Global petition for rulemaking asked NHTSA to revise the 92-percent minimum domestic passenger car standards retroactively for MYs 2012-2016 “to reflect 92 percent of the required average passenger car standard taking into account the fleet mix as it actually occurred, rather than what was forecast.” The petitioners stated that doing so would be “fully consistent with the statute.”²⁴⁸⁶

NHTSA explained in the NPRM that NHTSA understood that determining the 92 percent value ahead of the model year to which it applies, based on the information then available to the agency, would result in a different mpg number than if NHTSA determined the 92 percent value based on the information available at the end of the model year in question. NHTSA further explained that it understood that determining the 92 percent value ahead of time could make the minimum domestic passenger car standard more stringent than it could be if it were determined at the end of the model year, *if* manufacturers end up producing more larger-footprint passenger cars than what NHTSA had originally anticipated.

NHTSA therefore sought comment on the request by Alliance/Global. Additionally, recognizing the uncertainty inherent in projecting specific mpg values far into the future, NHTSA sought comment on whether the 92 percent value could be issued as a range, if NHTSA defined the mpg values associated with a CAFE standard (i.e., the footprint curve) as a range rather than as a single number. NHTSA referred to the sensitivity analysis included in the proposal and in the accompanying PRIA as a basis for such an mpg range “defining” the passenger car standard in any given model year. If NHTSA took that approach, 92 percent of that “standard” would also, necessarily, be a range. NHTSA broadly sought comment on that approach or other similar approaches.

²⁴⁸⁵ 77 FR 62624, 63028 (Oct. 15, 2012).

²⁴⁸⁶ Automobile Alliance and Global Automakers Petition for Direct Final Rule with Regard to Various Aspects of the Corporate Average Fuel Economy Program and the Greenhouse Gas Program (June 20, 2016) at 5, 17-18, available at https://www.epa.gov/sites/production/files/201609/documents/petition_to_epa_from_auto_alliance_and_global_automakers.pdf (hereinafter Alliance/Global Petition).

The Alliance and FCA commented that they “supported the NHTSA proposal” to calculate 92 percent as a range rather than as a single value, with the ultimate minimum domestic passenger car standard to be determined at the end of the MY to which it applies.²⁴⁸⁷ Both organizations cited compliance difficulties when the 92 percent calculated at the time of the rulemaking turns out to be more stringent than 92 percent of the final MY compliance obligations for passenger cars, and argued that minimum domestic passenger car standards should be recalculated as part of this rulemaking for all model years, rather than only MYs 2021-2026, in order to ameliorate that compliance difficulty retroactively. The Alliance argued that the 18 month lead time requirement should not be interpreted to apply to the minimum domestic passenger car standards, because if the 92 percent value is a range like the overall passenger car curve, then that value cannot be determined until after the model year is completed.²⁴⁸⁸ Because manufacturers’ individual compliance obligations are not subject to the 18 month lead time requirement, the Alliance concluded that the 92 percent should similarly not be.²⁴⁸⁹ Separately, Kreucher commented that NHTSA should expand the credit transfer provision to allow transferred credits to be used to meet the minimum domestic passenger car standard.²⁴⁹⁰

In contrast, the States and Cities and ACEEE opposed changes to the minimum domestic passenger car standard, with the States and Cities commenting that NHTSA “is proposing to retroactively revise the 92 percent based on actual fleet mix”²⁴⁹¹ and ACEEE simply noting that the Alliance/Global had requested that NHTSA do this.²⁴⁹² ACEEE stated that NHTSA did not have discretion to alter the statutory requirement, and argued that calculating 92 percent at the end of the model year was “entirely counter to the intent of the law—the so-called backstop is designed explicitly to protect against the market shifts for which the [industry is] asking the standard to be adjusted.”²⁴⁹³ The States and Cities similarly argued that “the 92 percent requirement is expressly intended to be a projection, not a retrospective recalculation,” and “the statute does not contemplate a ‘range,’ but rather a ‘minimum’ with a set value—92 percent. If Congress had intended the value to be a range, it would have included that language in the statute, and would not have determined the value with such specificity.”²⁴⁹⁴

While NHTSA sought comment on the possibility of establishing a range for the minimum domestic passenger car standards, upon further consideration, NHTSA is establishing

²⁴⁹² ACEEE, NHTSA-2018-0067-12122, Attachment (joint NGO comment to manufacturer petition for flexibilities), at 15.

²⁴⁹³ *Id.* ACEEE cited a NHTSA statement in the 2010 final rule establishing standards for MYs 2012-2016 in support of this argument, noting that NHTSA had said “this minimum standard was intended to act as a ‘backstop,’ ensuring that domestically-manufactured passenger cars reached a given mpg level *even if the market shifted in ways likely to reduce overall fleet mpg.*” *Id.* (emphasis added).

²⁴⁹⁴ States and Cities, NHTSA-2018-0067-11735, at 79.

single-mpg-value standards for each model year, as proposed. This is clearly consistent with the statutory text, and provides at least some of the relief sought by the automakers who commented on this issue, because the 92 percent calculations for MYs 2021-2025 result in less stringent standards than those that were calculated in 2012. NHTSA will continue to evaluate this issue going forward.

c) Attribute-based and defined by mathematical function

EISA requires NHTSA to set CAFE standards that are “based on 1 or more attributes related to fuel economy and express[ed]...in the form of a mathematical function.”²⁴⁹⁵ Historically, NHTSA has based standards on vehicle footprint and proposes to continue to do so for all the reasons described in previous rulemakings. As in previous rulemakings, NHTSA proposed to define the standards in the form of a constrained linear function that generally sets higher (more stringent) targets for smaller-footprint vehicles and lower (less stringent) targets for larger-footprint vehicles. These footprint curves are discussed in much greater detail in Section V above. NHTSA sought comment both on the choice of footprint as the relevant attribute and on the rationale for the constrained linear functions chosen to represent the standards; those comments and NHTSA’s responses are discussed above in Section V.

d) Number of model years for which standards may be set at a time

EISA also states that NHTSA shall “issue regulations under this title prescribing average fuel economy standards for at least 1, but not more than 5, model years.”²⁴⁹⁶ In the 2012 final rule, NHTSA interpreted this provision as preventing the agency from setting final standards for all of MYs 2017-2025 in a single rulemaking action, so the MYs 2022-2025 standards were termed “augural,” meaning “that they represent[ed] the agency’s current judgment, based on the information available to the agency [then], of what levels of stringency would be maximum feasible in those model years.”²⁴⁹⁷ That said, NHTSA also repeatedly clarified that the augural standards were in no way final standards and that a future *de novo* rulemaking would be necessary in order both to propose and to promulgate final standards for MYs 2022-2025.

In the NPRM, NHTSA proposed to establish new standards for MYs 2022-2026 and to revise the previously-established final standards for MY 2021. NHTSA explained that legislative history suggests that Congress included the five year maximum limitation so NHTSA would issue standards for a period of time where it would have reasonably realistic estimates of market conditions, technologies, and economic practicability (i.e., not set standards too far into the future).²⁴⁹⁸ However, NHTSA suggested that the concerns Congress sought to address by imposing those limitations are not present for nearer model years where NHTSA already has existing standards, and noted that revisiting existing standards is contemplated by both 49 U.S.C.

²⁴⁹⁵ 49 U.S.C. 32902(b)(3)(A).

²⁴⁹⁶ 49 U.S.C. 32902(b)(3)(B).

²⁴⁹⁷ 77 FR 62623, 62630 (Oct. 15, 2012).

²⁴⁹⁸ See 153 Cong. Rec. 2665 (Dec. 28, 2007).

§ 32902(c) and 32902(g). NHTSA stated that the agency therefore believed that it is reasonable to interpret section 32902(b)(3)(B) as applying only to the establishment of *new* standards rather than to the combined action of establishing new standards and amending existing standards.

Moreover, NHTSA argued, it would be an absurd result if the five year maximum limitation were interpreted to prevent NHTSA from revising a previously-established standard that the agency had determined to be beyond maximum feasible, while concurrently setting five years of standards not so distant from today. The concerns Congress sought to address are much starker when NHTSA is trying to determine what standards would be maximum feasible 10 years from now as compared to three years from now.

NADA commented that NHTSA has discretion and authority to set standards for MY 2026 and that the “statutory five-year rule is not a barrier to doing so,”²⁴⁹⁹ while the environmental group coalition argued that NHTSA “is limited to prescribing fuel economy standards for only five model years at a time,” but “[h]ere, NHTSA is setting standards for six model years, 2021 through 2026. This exceeds NHTSA’s statutory authority.”²⁵⁰⁰ Consumers Union argued that “[i]f Congress had intended the statute to only apply to the establishment of new standards, as the agencies contend, it certainly could have stated as such. But Congress did not include any language even hinting at this interpretation.”²⁵⁰¹

NHTSA continues to believe, consistent with the legislative history, that the five year limitation was intended to prevent NHTSA from setting standards too far into the future, recognizing that predicting the future is difficult. Consumers Union is correct that nothing in the statute compels the interpretation that the five year limitation applies only to the setting of new standards rather than to the combined action of establishing new standards and amending existing standards, but NHTSA does not believe that the statute precludes this interpretation, either. The statute allows NHTSA to revisit existing standards; the statute separately allows NHTSA to prescribe new standards for at least 1, but not more than 5, model years when it “issues regulations.” It is not clear whether the statute precludes multiple concurrent or quickly-sequential rulemakings “issuing regulations” for different periods of time. If this approach were used, for example, to try to set ten years’ worth of CAFE standards essentially at once, this would appear directly contrary to the statute. If this approach were used to revisit an existing standard and then (in a separate rulemaking) set five years’ worth of standards for the immediately ensuing model years, this would seem consistent with Congressional intent, but an unnecessary use of tax dollars that could be saved by consolidating agency (and commenter) work into a single rulemaking action. NHTSA does not believe that Congress intended to force the agency to waste resources, and continues to believe that the current interpretation is reasonable and appropriate.

e) Maximum feasible standards

As discussed above, EPCA requires NHTSA to consider four factors in determining what levels of CAFE standards would be maximum feasible, and NHTSA presents in the sections below its understanding of the meaning of those four factors. All factors should be considered, in the manner appropriate, and then the maximum feasible standards should be determined.

(1) Technological feasibility

“Technological feasibility” refers to whether a particular method of improving fuel economy is available for deployment in commercial application in the model year for which a standard is being established. Thus, NHTSA is not limited in determining the level of new standards to technology that is already being commercially applied at the time of the rulemaking. For the proposal, NHTSA explained that it had considered a wide range of technologies that improve fuel economy, subject to the constraints of EPCA regarding how to treat alternative fueled vehicles, such as battery-electric vehicles, in determining maximum feasible standards, and considering the need to account for which technologies have already been applied to which vehicle model/configuration, and the need to realistically estimate the cost and fuel economy impacts of each technology. NHTSA explained that it had not attempted to account for every technology that might conceivably be applied to improve fuel economy and considered it unnecessary to do so given that many technologies address fuel economy in similar ways.²⁵⁰² NHTSA noted that technological feasibility and economic practicability are often conflated, trying to explain that the question of whether a fuel-economy-improving technology does or will exist (technological feasibility) is a different question from what economic consequences could ensue if NHTSA effectively requires that technology to become widespread in the fleet and the economic consequences of the absence of consumer demand for technology that are projected to be required (economic practicability). NHTSA explained that it is therefore possible for standards to be technologically feasible but still beyond the level that NHTSA determines to be maximum feasible due to consideration of the other relevant factors.

The States and Cities commenters argued that NHTSA’s interpretation of the technological feasibility factor was unreasonable, stating that “...fuel economy standards under EPCA are ‘intended to be technology forcing’ because Congress recognized ‘that ‘market forces . . . may not be strong enough to bring about the necessary fuel conservation which a national energy policy demands.’”²⁵⁰³ The States and Cities commenters thus argued that all alternatives less stringent than the baseline/augural standards alternative were unacceptable because they

²⁵⁰² For example, NHTSA has not considered high-speed flywheels as potential energy storage devices for hybrid vehicles; while such flywheels have been demonstrated in the laboratory and even tested in concept vehicles, commercially available hybrid vehicles currently known to NHTSA use chemical batteries as energy storage devices, and the agency has considered a range of hybrid vehicle technologies that do so.

²⁵⁰³ States and Cities, NHTSA-2018-0067-11735, Detailed Comments, at 66, citing CAS, 793 F.2d at 1339 (citing S. Rep. No. 179, 94th Cong., 1st Sess. 2 (1975) at 9).

would not force technologies to be developed and applied, and NHTSA had “conce[ded] that the technology already exists that could meet the more stringent augural standards.”²⁵⁰⁴ These commenters stated that “NHTSA is therefore impermissibly and unreasonably (and even implicitly) re-interpreting this factor in a manner contrary to the plain meaning of ‘feasibility’ and ignoring EPCA’s technology-forcing purpose. See *Chevron*, 467 U.S. at 843; *Fox Television*, 556 U.S. at 515 (‘An agency may not ... depart from a prior policy *sub silentio*.’)” CARB²⁵⁰⁵ and CBD *et al.*²⁵⁰⁶ also argued that EPCA was intended to be technology forcing.

The States and Cities commenters also argued that NHTSA had previously stated in rulemakings that it considered “*all* types of technologies that improve real-world fuel economy,” but in the NPRM NHTSA stated instead that it had “not attempted to account for every technology that might conceivably be applied to improve fuel economy and consider[ed] it unnecessary to do so given that many technologies address fuel economy in similar ways.”²⁵⁰⁷ The States and Cities commenters stated that “[t]his is an unexplained departure from the agency’s past practice and prior interpretation of ‘technological feasibility,’ citing *Fox Television*, and argued that NHTSA had not explained “1) what ‘similar ways’ means, or 2) why the fact that a technology that might improve fuel economy ‘in similar ways’ to another technology obviates NHTSA’s obligation to consider its availability, particularly given the differences in costs between different technologies.”²⁵⁰⁸ The States and Cities commenters pointed to the examples of HCR1 and HCR2 as technologies “already widely available in the market” that should have been considered, and claimed that NHTSA had “failed to even consult with EPA regarding which technologies the agency considered,” “result[ing] in fundamentally flawed predictions of what technology can be applied in model years 2021-2026.”²⁵⁰⁹

Mazda, in contrast, stated that it agreed that “mere development and introduction of advanced fuel efficient technologies is not sufficient for manufacturers to comply with established GHG and fuel efficiency standards. The technologies must be widely adopted by consumers for them to provide the expected environmental benefit.”²⁵¹⁰ Mr. Kreucher stated that manufacturers have been applying “unprecedented levels of technology” but are still falling short of their compliance obligations, pointing in particular to light truck compliance in MY 2016.

Kreucher argued that “[t]his indicates a serious overestimation of technological feasibility in the prior [2012] analysis that must be corrected.”²⁵¹¹

UCS stated that the NPRM analysis “undermined” an assessment of “technical feasibility,” by “paint[ing] fuel-saving technologies as less effective and more costly than real-world data indicate,” through several mechanisms.²⁵¹² First, UCS argued that the analysis had underestimated ICE efficiency possibilities, “frequently ignoring technology that is already commercialized or is widely anticipated to be readily available within the timeframe of the standards.”²⁵¹³ Second, UCS suggested that the NPRM analysis had “overstate[d] the degree to which manufacturers have deployed some of the most cost-effective technologies, while errors in full vehicle simulation and rampant disregard for the current state of technology underestimates the potential for future improvement.”²⁵¹⁴ UCS claimed that “[f]requently the agencies have departed from past precedence in specific ways *in order to* increase technology costs associated with technology deployment, sometimes failing to provide even a glimmer of reasonable justification for such decisions.”²⁵¹⁵ (emphasis added) Third, UCS argued that the model had been deliberately constructed to avoid choosing the most cost-effective technology pathways, showing higher costs and more future overcompliance than UCS analysis showed.²⁵¹⁶ Finally, UCS argued that better modeling of credit trading and use would further reduce technology costs. UCS concluded that “The mischaracterization of technology and unrealistic model construction lead to an inaccurate assessment of technological feasibility, effectively undermining this factor’s weight in considering maximum feasible standards.”²⁵¹⁷

Contrary to the assertion by several commenters that NHTSA has historically claimed that it *must* set technology-forcing standards, NHTSA has previously described the technological feasibility factor as *allowing* the agency to set standards that force the development and application of new fuel-efficient technologies.²⁵¹⁸ In the same preamble section in which that description was set forth, NHTSA stated that “[i]t is important to remember that technological feasibility must also be balanced with the other of the four statutory factors. Thus, while ‘technological feasibility’ can drive standards higher by assuming the use of technologies that are not yet commercial, ‘maximum feasible’ is also defined in terms of economic practicability, for example, which might caution the agency against basing standards (even fairly distant standards) *entirely* on such technologies.”²⁵¹⁹ NHTSA further stated that “...as the ‘maximum feasible’ balancing may vary depending on the circumstances at hand for the model year in

²⁵¹⁹ *Id.*

which the standards are set, the extent to which technological feasibility is simply met or plays a more dynamic role may also shift.”²⁵²⁰

NHTSA continues to believe that, for purposes of this rulemaking covering standards for MYs 2021-2026, the crucial question is not whether technologies exist to meet the standards—they do. The question is rather, given that the technology exists, how much of it should be required to be added to new cars and trucks in order to conserve more energy, and how to appropriately balance additional energy conserved and additional cost for new vehicles. Regardless of whether technological feasibility *allows* the agency to set technology-forcing standards, technological feasibility does not *require*, by itself, NHTSA to set technology-forcing standards if other statutory factors would point the agency in a different direction. NHTSA has expressed this interpretation of technological feasibility over the course of multiple rulemakings.²⁵²¹ The States and Cities commenters appear, at the root, to be contesting the agency’s determination of maximum feasible standards, by way of arguing that NHTSA must interpret the technological feasibility factor as necessarily driving greater energy conservation. The balancing of factors to determine maximum feasible standards is a separate issue, for which EPCA/EISA gives NHTSA considerable discretion.

The States and Cities commenters focus on previous rulemaking language when they suggest that the agency was arbitrary and capricious for not explaining more fully why it need not expressly evaluate every single technology that does or could exist in MYs 2021-2026. While NHTSA stated in 2012 that it had “considered all types of technologies that improve real-world fuel economy, including air-conditioner efficiency and other off-cycle technology, PHEVs, EVs, and highly-advanced internal combustion engines not yet in production,”²⁵²² that statement was only one in a larger discussion. The 2012 final rule also stated expressly that “[t]here are a number of other potential technologies available to manufacturers in meeting the 2017-2025 standards *that the agencies have evaluated but have not considered* in our final analyses. These include HCCI, ‘multi-air’, and camless valve actuation, and other advanced engines currently under development.”²⁵²³ (emphasis added) Thus, even under the prior analysis that some commenters appear to prefer, it is not entirely correct to say that NHTSA had considered *all* technologies in existence or that could exist, because some technologies were clearly and purposely left out of the prior rule’s analysis. In response to commenters’ apparent confusion regarding NHTSA’s statement that it did not consider technologies that improved fuel economy in “similar ways” as other technologies discussed in the NPRM, the meaning behind that statement was discussed at greater length in the section of the NPRM that substantively covered those technologies. For example, in discussing the “HCR2” technology, the agencies explained that while the agencies were not modeling HCR2 expressly due to concerns that it

²⁵²⁰ *Id.*

²⁵²¹ *Id.*, see also 75 FR at 25605 (May 7, 2010).

²⁵²² 77 FR at 63037 (Oct. 15, 2012).

²⁵²³ 77 FR at 62706 (Oct. 15, 2012).

remained “entirely speculative,” “[t]he CAFE model allows for incremental improvement over existing HCR1 technologies with the addition of improved accessory devices (IACC), a technology that is available to be applied on many baseline MY 2016 vehicles with HCR1 engines and may be applied as part of a pathway of compliance to further improve the effectiveness of existing HCR1 engines.”²⁵²⁴ In this and in other instances, technologies included in the analysis improved fuel economy in similar ways to other technologies not included. Here, HCR1, when combined with IACC, results in “a step past” HCR1, which is similar to the unproven HCR2. As in the 2012 rule, the agencies explained in the NPRM why certain technologies were not considered, and sought comment. In response to comments received, some technologies have been added to the analysis for the final rule. See Section VI for more information.

While the agencies respond to many of UCS’s analytical concerns in Sections IV and VI (which include extensive discussion of changes made in response to comments), NHTSA recognizes that some commenters believe that more technologies are “available for deployment” more widely, and sooner, than the final rule’s analysis reflects. This question has long been a topic of debate in CAFE and CO₂ rulemakings—the agencies consider which technologies can be applied to which vehicles in which model years in order to assess the costs and benefits of pushing the industry to reach different levels of standards, which in turn helps to inform stringency determinations. In response to comments, the agencies have expanded the number of technologies and the vehicles to which they may be applied for this final rule, but continue to disagree that certain technologies can be applied widely in the rulemaking timeframe. NHTSA does not believe, for example, that HCCI will be unavailable for widespread application in the rulemaking timeframe because it *wishes* to believe this prediction—NHTSA believes it based on the fact that HCCI has been in the research phase for several decades, and the only production applications to date use a highly-limited version that restricts HCCI combustion to a very narrow range of engine operating conditions. Section VI contains further discussion of these issues.

(2) *Economic practicability*

“Economic practicability” has traditionally referred to whether a standard is one “within the financial capability of the industry, but not so stringent as to” lead to “adverse economic consequences, such as a significant loss of jobs or unreasonable elimination of consumer choice.”²⁵²⁵ In evaluating economic practicability, NHTSA considers the uncertainty surrounding future market conditions and consumer demand for fuel economy alongside consumer demand for other vehicle attributes. NHTSA has explained in the past that this factor can be especially important during rulemakings in which the auto industry is facing significantly

²⁵²⁴ 83 FR at 43038 (Aug. 24, 2018).

²⁵²⁵ 67 FR 77015, 77021 (Dec. 16, 2002).

adverse economic conditions (with corresponding risks to jobs). Consumer acceptability is also a major component of economic practicability,²⁵²⁶ which can involve consideration of anticipated consumer responses not just to increased vehicle cost, but also to the way manufacturers may change vehicle models and vehicle sales mix in response to CAFE standards. In attempting to determine the economic practicability of attribute-based standards, NHTSA considers a wide variety of elements, including the annual rate at which manufacturers can increase the percentage of their fleet that employs a particular type of fuel-saving technology,²⁵²⁷ and manufacturer fleet mixes. NHTSA also considers the effects on consumer affordability resulting from costs to comply with the standards, and consumers' valuation of fuel economy, among other things.

Prior to the MYs 2005-2007 rulemaking under the non-attribute-based (fixed value) CAFE standards, NHTSA generally sought to ensure the economic practicability of standards in part by setting them at or near the capability of the "least capable manufacturer" with a significant share of the market, i.e., typically the manufacturer whose fleet mix was, on average, the largest and heaviest, generally having the highest capacity and capability so as not to limit the availability of those types of vehicles to consumers. In the first several rulemakings establishing attribute-based standards, NHTSA applied marginal cost-benefit analysis, considering both overall societal impacts and overall consumer impacts. Whether the standards maximize net benefits has thus been a significant, but not dispositive, factor in the past for NHTSA's consideration of economic practicability. Executive Order 12866, as amended by Executive Order 13563, states that agencies should "select, in choosing among alternative regulatory approaches, those approaches that maximize net benefits. . ." In practice, however, agencies, including NHTSA, must consider that the modeling of net benefits does not capture all considerations relevant to economic practicability. Therefore, as in past rulemakings, NHTSA explained in the NPRM that it was considering net societal impacts, net consumer impacts, and other related elements in the consideration of economic practicability.

NHTSA's consideration of economic practicability depends on a number of elements. Expected availability of capital to make investments in new technologies matters; manufacturers' expected ability to sell vehicles with certain technologies matters; likely consumer choices matter; and so forth. NHTSA explained in the NPRM that NHTSA's analysis of the impacts of the proposal incorporated assumptions to capture aspects of consumer preferences, vehicle attributes, safety, and other elements relevant to an impacts estimate; but stated that it is difficult to capture every such constraint. Therefore, NHTSA explained, it is well within the agency's discretion to deviate from the level at which modeled net benefits are maximized if the agency concludes that that level would not represent the maximum feasible level for future CAFE

²⁵²⁶ See, e.g., *Center for Auto Safety v. NHTSA (CAS)*, 793 F.2d 1322 (D.C. Cir. 1986) (Administrator's consideration of market demand as component of economic practicability found to be reasonable); see also *Public Citizen v. NHTSA*, 848 F.2d 256 (Congress established broad guidelines in the fuel economy statute; agency's decision to set lower standards was a reasonable accommodation of conflicting policies).

²⁵²⁷ For example, if standards effectively require manufacturers to make technologies widely available that consumers do not want, or to make technologies widely available before they are ready to be widespread, NHTSA believes that these standards could potentially be beyond economically practicable.

standards. Economic practicability is complex, and like the other factors must also be considered in the context of the overall balancing and EPCA's overarching purpose of energy conservation. Depending on the conditions of the industry and the assumptions used in the agency's analysis of alternative standards, NHTSA stated that it could well find that standards that maximize net benefits, or that are higher or lower, could be at the limits of economic practicability, and thus potentially the maximum feasible level, depending on how the other factors are balanced.

NHTSA also stated in the NPRM that while the agency would discuss safety as a separate consideration, NHTSA also considered safety as closely related to, and in some circumstances a subcomponent of, economic practicability. On a broad level, manufacturers have finite resources to invest in research and development. Investment into the development and implementation of fuel saving technology necessarily comes at the expense of investing in other areas such as safety technology. On a more direct level, when making decisions on how to equip vehicles, manufacturers must balance cost considerations to avoid pricing further consumers out of the market. As manufacturers add technology to increase fuel efficiency, they may decide against installing additional safety equipment to reduce cost increases. And as the price of vehicles increase beyond the reach of more consumers, such consumers continue to drive or purchase older, less safe vehicles. In assessing practicability, NHTSA also considers the harm to the Nation's economy caused by highway fatalities and injuries.

CARB, the States and Cities commenters, and UCS all commented that the NPRM analysis, as the States and Cities put it, had "inexplicably inflat[ed] technology costs and rel[ied] on flawed models to predict impacts on vehicle sales."²⁵²⁸ Both CBD *et al.* and UCS suggested that it was incorrect to assume that manufacturers would pass on 100 percent of cost increases as price increases to consumers.²⁵²⁹ UCS further stated that "The agencies have then strategically excluded well-established academic literature to limit the assumptions used to define a consumer's willingness to pay in ways that further increase costs to consumers and/or decrease the consumer benefits of fuel economy and greenhouse gas emissions."²⁵³⁰ UCS argued that assuming full pass-through of cost increases as price increases and assuming that consumers may not fully value improvements in fuel economy "arbitrar[ily] ... depress the sales of highly fuel-efficient vehicles in the model by systematically negating consumer benefits of these vehicles."²⁵³¹ The States and Cities further argued that NHTSA had not "substantiated its concern that an increase in new vehicle prices would place a particular burden on 'low-income purchasers,'" and stated that NHTSA had "assume[d], without explanation, that" less-stringent fuel economy standards resulted in greater net savings for consumers, which NHTSA "acknowledge[d], without justification, 'is a significantly different analytical result from the

²⁵³¹ *Id.*

2012 final rule.”²⁵³² The States and Cities commenters implied that this different result and NHTSA’s “failure to acknowledge it” was impermissible under the standard set forth in *Fox Television*.²⁵³³

A number of commenters stated that the NPRM’s estimates of job losses associated with the proposal conflicted with NHTSA’s concerns about job losses if more stringent standards were promulgated. CBD *et al.* argued that NHTSA could not reasonably conclude that job losses make less-stringent standards more economically practicable than more-stringent standards.²⁵³⁴ The States and Cities commenters stated that “[b]y declining to address its own findings of significant job losses in the auto sector, NHTSA has ignored an important aspect of the problem and failed to propose a ‘rational connection between the facts found and the choice made.’”²⁵³⁵ The States and Cities commenters also argued that “the agency failed to acknowledge or explain its break with its own interpretation and practice of considering whether standards would cause a ‘significant loss of jobs.’”²⁵³⁶ Some commenters argued that more-stringent standards would create more jobs (and conversely, that less-stringent standards would result in job losses), primarily for supplier companies,²⁵³⁷ and some noted that other studies had concluded that more-stringent standards would increase employment, citing, for example, the report by Synapse Energy Economics, Inc. on “Cleaner Cars and Job Creation.”²⁵³⁸ Some commenters further argued that less-stringent standards would hurt U.S. GDP,²⁵³⁹ and some argued that they would hurt U.S. industry’s international competitiveness because other countries/regions have more stringent standards, and investment may shift to those countries if U.S. standards do not continue to compel it.²⁵⁴⁰ The States and Cities commenters stated that failing to address fully “the negative employment and GDP impacts of the Proposed Rollback is an abdication of NHTSA’s clear statutory duty to consider the economic practicability of its proposed standards, and an impermissible interpretation of the statutory text.”²⁵⁴¹

Commenters disagreed on whether and how NHTSA should consider consumer demand. Mr. Kreucher, the Texas Congressional Delegation,²⁵⁴² and Senator Inhofe,²⁵⁴³ among others, all argued that considering consumer demand for fuel economy was important, while other commenters argued that while it may be permissible for NHTSA to consider consumer demand,

NHTSA could not elevate that consideration above others. CARB and the States and Cities commenters both cited language from *CAS v. NHTSA* for the premise that “Congress intended energy conservation to be a long-term effort that would continue through temporary improvements in energy availability. Thus, it would clearly be impermissible for NHTSA to rely on consumer demand to such an extent that it ignored the overarching goal of fuel conservation.”²⁵⁴⁴ The Minnesota agencies stated that “making sweeping assumptions about consumer preferences should not trump the clear public benefit to reducing GHG emissions through these standards.”²⁵⁴⁵ Mr. Kreucher commented, in contrast, that consumer preferences are driven entirely by “[l]ong term fuel price expectations and fuel price alone,” and disagreed with the historical “implicit assumption that if you build it customers will come.”²⁵⁴⁶

The Minnesota agencies argued that focusing on consumer preferences represented an “unreasonable and unprecedented shift in interpretation.”²⁵⁴⁷ The States and Cities commenters stated similarly that NHTSA had “redefined ‘economically practicable’ to categorically exclude standards that, based on some unspecified metric, ‘widely apply technologies that consumers do not want,’” and argued that “NHTSA has offered no explanation for how it would define ‘wide application,’ much less how it would supposedly determine what consumers do or do not want.”²⁵⁴⁸ The States and Cities commenters argued that it was internally inconsistent (and therefore arbitrary and capricious) for NHTSA to rely in its justification on concerns about consumer acceptance of technologies, while concurrently “acknowledging the ‘extensive debate over how much consumers do (and/or should) value fuel savings and fuel economy as an attribute in new vehicles’”²⁵⁴⁹ The States and Cities commenters stated that the NPRM’s modeling “assume[ed] that consumers assign no value to fuel savings whatsoever,” and that “This assumption is not only implausible but also flies in the face of the Agency’s own statements that consumers likely value between half of and all future fuel savings.”²⁵⁵⁰

With regard to whether consumers *do* want more fuel economy, NESCAUM stated that “the most recent surveys indicate that consumers continue to place a high value on fuel efficient vehicles of all types,”²⁵⁵¹ while Alliance for Vehicle Efficiency stated that “Consumers have adopted incremental changes to new vehicles that increase fuel economy that don’t compromise on power, size or safety.”²⁵⁵² The States and Cities commenters argued that “consumer choice is, in fact, enhanced by providing consumers with the option of purchasing higher-efficiency

vehicles.”²⁵⁵³ CBD *et al.* and the States and Cities commenters stated that NHTSA had simply made assertions about consumer demands without supporting evidence,²⁵⁵⁴ with the States and Cities commenters also arguing that the fuel price assumptions in the NPRM were “unsupported” and “contradicted by recent evidence,” despite NHTSA’s arguments that low fuel prices made “fuel efficiency less attractive to consumers.”²⁵⁵⁵ Somewhat in contrast, NESCAUM stated that “[g]iven recent consumer preferences for larger vehicles, maximizing fuel efficiency and GHG emission reductions in larger footprint vehicles is even more important,” noting that footprint based standards “are intentionally flexible to accommodate industry and consumer preferences.”²⁵⁵⁶ NESCAUM also stated that many HEV/PHEV/EV models are now available and that their sales “reflect[] growing consumer acceptance of the technology, ...despite the low availability of electric vehicle models in the Northeast Section 177 States and the auto industry’s continuing failure to actively market [them].”²⁵⁵⁷

Regarding the NPRM’s statement that safety could be a subcomponent of economic practicability, the States and Cities commenters stated that this was “an unreasonable interpretation of this factor, given that safety concerns are not discussed in EPCA and have no direct correlation to whether a standard is economically practicable.”²⁵⁵⁸ The States and Cities commenters further stated that “NHTSA has never before analyzed safety considerations as falling under this factor, and fails to explain its reason for doing so now,”²⁵⁵⁹ and said that it was “unmoored from reality” for NHTSA to state without support that “[i]nvestment into the development and implementation of fuel saving technology necessarily comes at the expense of investing in other areas such as safety technology.”²⁵⁶⁰ The States and Cities commenters argued that investment in fuel economy rather than safety “does not explain why safety should be folded into a consideration of whether standards are economically practicable.”²⁵⁶¹ IPI argued that “[i]t is arbitrary for NHTSA to count alleged safety costs as support for its propose [*sic*] rollback both under the economic practicability factor and as its own separate ‘bolster[ing] factor,’ and yet never fully monetize climate- and pollution-related deaths and other welfare impacts under either the need to conserve energy factor nor under the economic practicability factor.”²⁵⁶²

In response to these comments, NHTSA continues to believe that it is reasonable to interpret “economic practicability” as the agency has long interpreted it: as a question of whether a standard is one “within the financial capability of the industry, but not so stringent as

to” lead to “adverse economic consequences, such as a significant loss of jobs or the unreasonable elimination of consumer choice.”²⁵⁶³ NHTSA disagrees that this interpretation is new or divergent from past interpretations of economic practicability—this is, to the word, the same interpretation set forth in the 2010 and 2012 final rules, and in multiple earlier rules. Commenters disagreeing with the NPRM’s assessment of economic practicability seem, fundamentally, to be disagreeing with how NHTSA *applied* this interpreted definition of economic practicability to the information then before the agency, and also with the agency’s conclusion of how economic practicability weighed against the other statutory factors.

The following text explains why NHTSA continues to believe that the pieces of the analysis it categorizes as relevant to economic practicability fit within the long-standing definition of that factor. Section VIII.B.4 below will explain how the agency has considered those pieces of the analysis in balancing economic practicability with the other statutory factors.

NHTSA has consistently described the manner in which it applies the “economic practicability” factor, and has given considerable weight to the phrasing of this description. Parsing the words of this description can be useful:

The core of the description is the phrase “within the financial capability of the industry,” but not so stringent as to lead to “adverse economic consequences.” The following clause “such as a significant loss of jobs or the unreasonable elimination of consumer choice” is set off by a comma from “consequences,” and use of the phrase “such as” indicates that it is a nonrestrictive clause.²⁵⁶⁴ A nonrestrictive clause means that “significant loss of jobs” and “unreasonable elimination of consumer choice” are *examples* of “adverse economic consequences,” but are not an exclusive list of the possible adverse economic consequences that NHTSA may consider. Further evidence that this clause was intended simply to offer examples comes from the 1977 final rule establishing passenger car standards for MYs 1981-1984, in which NHTSA examined the potential meaning of “economic practicability” at length and concluded that it should be interpreted as “requiring the standards to be within the financial capability of the industry, but not so stringent as to threaten substantial economic hardship for the industry,” i.e., lacking the final clause.²⁵⁶⁵

A number of commenters took issue with NHTSA’s consideration of consumer demand, citing the 1986 D.C. Circuit decision *CAS v. NHTSA* for the proposition that consumer demand cannot drive the balancing of factors in determining maximum feasible standards. In that case, the D.C. Circuit stated that “[i]t is axiomatic that Congress intended energy conservation to be a

²⁵⁶³ 67 FR 77015, 77021 (Dec. 16, 2002).

²⁵⁶⁴ See Strunk, William and E.B. White, *The Elements of Style*, Fourth Edition (2000), Rule 3, at 2-7.

²⁵⁶⁵ 42 FR 33534, 33537 (Jun. 30, 1977). It is worth noting that the agency considered and rejected an interpretation of economic practicability at that time based solely on cost-benefit analysis, stating “A cost-benefit analysis would be useful in considering these factors [of economic practicability], but sole reliance on such an analysis would be contrary to the mandate of the act.” *Id.*

long term effort that would continue through temporary improvements in energy availability. Thus, it would clearly be impermissible for NHTSA to rely on consumer demand to such an extent that it ignored the overarching goal of fuel conservation.”²⁵⁶⁶ NHTSA agrees that the *CAS* decision makes this point, and that the 9th Circuit decision in *CBD v. NHTSA* also underscored that the overarching purpose of EPCA is energy conservation. That said, the *CAS* decision also contains a number of other points that are relevant both to the facts at hand in *this* rulemaking and NHTSA’s current use of consumer demand as an aspect of economic practicability and as a consideration in determining maximum feasible standards. NHTSA will discuss *CAS* more extensively below in Section VIII.B.4, but this section will cover it briefly, specifically with respect to NHTSA’s interpretation of economic practicability.

As noted in the NPRM and in the 2012 final rule, the *CAS* decision found NHTSA’s consideration of market demand as a component of economic practicability reasonable.²⁵⁶⁷ In *CAS*, petitioners the Center for Auto Safety, Public Citizen, Union of Concerned Scientists, and Environmental Policy Institute sued NHTSA over CAFE standards for MY 1986, arguing that NHTSA could not determine stringency on the basis of low expected consumer demand for fuel economy, and “that technology permitted greater fuel savings and that the statutorily required ‘maximum feasible’ level of fuel economy is higher than the standard” determined by NHTSA.²⁵⁶⁸ The court followed *Chevron* in evaluating whether NHTSA could consider consumer demand, and found that Congress had not directly spoken to the consideration of consumer demand. The court then assessed whether NHTSA’s interpretation of the statute “represents a reasonable accommodation of conflicting policies that were committed to the agency’s care by statute,” stating that “The agency’s interpretation of the statutory requirements is due considerable deference and must be found adequate if it falls within the range of permissible constructions.”²⁵⁶⁹

In assessing NHTSA’s interpretation, the court stated that “Consumer demand is not specifically designated as a factor, but neither is it excluded from consideration; the factors of ‘technological feasibility’ and ‘economic practicability’ are each broad enough to encompass the concept. Thus, the unadorned language of the statute does not indicate a congressional intent concerning the precise objections raised by the petitioners.” The court then examined EPCA’s legislative history and concluded that “this language neither precludes nor requires lower standards when consumer demand for heavy vehicles is strong. The agency is directed to weigh the ‘difficulties of individual automobile manufacturers;’ there is no reason to conclude that difficulties due to consumer demand for a certain mix of vehicles should be excluded.”²⁵⁷⁰ The

²⁵⁷⁰ *CAS*, at 1338-1339.

court even noted that “the petitioners [did] not challenge the consideration of consumer demand *per se*, but rather the weight the agency has given the factor in downgrading standards...”²⁵⁷¹

NHTSA continues to believe that it is reasonable to consider consumer demand as an element of economic practicability, as the *CAS* court recognized. Comments objecting to the consideration of consumer demand appear to focus more, like the petitioners in *CAS*, on the agency’s focus on consumer demand in the overall balancing of factors to determine what CAFE standards would be maximum feasible, insofar as they are expressing concern about consumer demand undermining energy conservation. Again, this question will be addressed further in Section VIII.B.4 below. To the extent that commenters dispute *any* consideration of consumer demand, the D.C. Circuit put that question to rest decades ago.

Related to the agency’s consideration of consumer demand, a number of commenters took issue with the agencies’ estimates of the cost of meeting higher fuel economy standards, arguing essentially that the analysis was deliberately constructed to inflate costs and minimize consumer willingness to pay for fuel economy improvements in order to arrive at a policy conclusion that higher fuel economy standards would not be economically practicable. NHTSA does not believe that commenters mean to argue with the agency’s legal interpretation (i.e., the *consideration* of cost as an aspect of economic practicability), but rather with the agencies’ analytical findings which inform that consideration. Comments on those analytical findings, and the agencies’ responses and changes to the analysis in response to those comments, are discussed in Sections VI and VII above. Consumer willingness to pay for additional fuel economy in their new vehicles, in particular, is represented throughout the final rule analysis as 2.5 years—that is, that consumers value, and manufacturers will voluntarily add, fuel economy-improving technology that pays for itself in fuel savings within 2.5 years.

More generally, NHTSA believes that the cost of meeting CAFE standards is inherently relevant to assessing whether those standards are “within the financial capability of the industry but not so stringent as to lead to adverse economic consequences,” for two primary reasons. First, vehicle manufacturers tend to have relatively fixed budgets for R&D and production, which are tied to overall revenues. If more of those budgets are spent on improving fuel economy, less of those budgets are available to spend on other vehicle characteristics (such as advanced safety features, or better performance or utility) that might improve sales. Offering less of those other vehicle characteristics in a market where many consumers are not particularly focused on fuel economy could lead to adverse economic consequences for those manufacturers. Manufacturers cannot simply increase budgets or turn limited resources toward supplying more of vehicle characteristics that do not motivate most sales. To the extent that more stringent standards drive manufacturing costs higher and those costs are passed forward to consumers in the form of price increases, those price increases can affect vehicle sales to some extent. NHTSA understands that some commenters disagree that higher manufacturing costs are necessarily passed forward to consumers in the way that the agencies have modeled them being

²⁵⁷¹ *CAS*, at 1340.

passed forward, but the agencies do not have adequate information on which to base a different approach. Commenters disagreeing with this approach generally object on two fronts: first, because they believe that automakers cross-subsidize cost increases by raising the prices of certain models rather than all models, and second, because they believe that automakers could absorb regulatory costs and reduce profits. The agencies do not have enough information to model either of those issues in a meaningful way. Some amount of cross-subsidization no doubt occurs, but automakers closely hold pricing strategy information. The agencies do not attempt to model automakers voluntarily reducing profits in response to standards, again in part because we do not have sufficient information, but also because these companies are publicly-traded and taking losses is not a long-term solution for companies whose success is measured by profitability. NHTSA believes that the analytical approach used today is reasonable given the information available to the agencies. While today's analysis does not show large sales effects due to price increases, and even accounting for fuel economy differences in this final rule *still* does not show large sales effects, it seems reasonable to call negative sales effects "adverse economic consequences."

Also related to consumer demand, NHTSA has previously considered manufacturer "shortfalls" as an aspect of economic practicability.²⁵⁷² The CAFE standards are corporate average standards, by definition, giving manufacturers the flexibility to decide how to distribute fuel economy-improving technologies throughout their fleet. In other words, no given vehicle need, itself, meet a standard or even its "target" on the target curve, as long as the fleet as a whole meets the standard. However, CAFE compliance is measured on a sales-weighted basis, so if a manufacturer ultimately sells more vehicles that perform poorly relative to their targets than it sells vehicles that beat their targets, the manufacturer may fall short of its compliance obligation despite having applied fuel economy-improving technologies in amounts that the manufacturer originally anticipated would result in compliance. Recent compliance trends have illustrated this phenomenon, as discussed in Section IV above. When fuel is relatively inexpensive, Americans tend to be less interested in saving money on fuel, and thus less interested in fuel economy as compared to other vehicle attributes. Compliance shortfalls represent this consumer decision-making playing out in the market, and can thus be evidence of economic impracticability if sufficiently widespread.²⁵⁷³

As with the above-discussed aspects of economic practicability, commenters who objected to NHTSA's consideration of employment impacts disagreed less with the principle of considering employment impacts, and more with how NHTSA discussed employment impacts in the proposal's justification given the NPRM's findings on employment. Namely, the NPRM included a simplistic analysis that converted reduced technology costs under the preferred alternative relative to the augural standards into "job years" metric and estimated U.S. auto

²⁵⁷² See 77 FR at 63040-43 (Oct. 15, 2012).

²⁵⁷³ See, e.g., Alliance comments (Full Comment Set) at 25-29, describing automaker shortfalls in terms of fleet fuel economy increases required by augural and prior standards.

sector labor would be slightly reduced under the proposal as compared to under the augural standards (reflecting those reduced technology costs). Although new vehicle sales increased slightly under the NPRM's preferred alternative, this was offset because "manufacturing, integrating, and selling less technology means using less labor to do so."²⁵⁷⁴ However, NHTSA expressed concern in the proposal justification section that "there could be potential for...loss of U.S. jobs...under nearly all if not all of the regulatory alternatives considered..."²⁵⁷⁵ A number of commenters argued that if more stringent standards led to higher employment, as the NPRM (and also outside analyses) appeared to show, there was no way that less stringent standards could be *more* economically practicable.

As in the NPRM, NHTSA recognizes that the employment analysis for this final rule does not capture certain potential effects that may be important. NHTSA explained in the NPRM that the NPRM's employment analysis did not account for the risks that vehicle sales may be facing a bubble situation, or that manufacturers facing higher production costs might choose to move production overseas.²⁵⁷⁶

Commenters addressing NHTSA's consideration of safety as an aspect of economic practicability argued generally that EPCA did not call for discussion of safety concerns, and that it was unreasonable to assume that requiring higher levels of fuel economy might preclude investment in further vehicle safety improvements. NHTSA has already explained above that the long-standing definition of "economic practicability" lists example "adverse economic consequences" in a nonrestrictive clause format, meaning that other things besides employment and consumer choice impacts could cause economic consequences and be relevant to economic practicability. NHTSA believes that it is reasonable and appropriate to consider some aspects of safety as part of its consideration of economic practicability, because NHTSA continues to believe that vehicle manufacturers have finite budgets for R&D and production that may be spent on fuel economy improvements when they may otherwise be spent on safety improvements, among other things that consumer value. Some commenters said that that was not a reasonable assumption, but it is supported by statements from vehicle manufacturers,²⁵⁷⁷ and NHTSA does not have a reason to disbelieve that companies have limited budgets. Moreover, case law does not object to consideration of safety as an aspect of economic practicability.²⁵⁷⁸ With regard to

²⁵⁷⁴ 83 FR at 43436 (Aug. 24, 2018).

²⁵⁷⁵ *Id.* at 43216.

²⁵⁷⁶ *Id.* at 43224-25.

²⁵⁷⁷ *See, e.g.,* Toyota comments at 6, NHTSA-2018-0067-12098 ("There are now more realistic limits placed on the number of engines and transmissions in a powertrain portfolio which better recognizes manufacturers must manage limited engineering resources and control supplier, production, and service costs.")

²⁵⁷⁸ *Competitive Enterprise Institute v. NHTSA*, 901 F.2d 107, 120, n. 11 ("Petitioners have never clearly identified the precise statutory basis on which safety concerns should be factored into the CAFE scheme, although they alluded to occupant safety as part of the 'economic practicability' criterion in their MY 1989 petition to NHTSA and at oral argument. We do not find this failure fatal, however, because NHTSA has always examined the safety consequences of the CAFE standards in its overall consideration of relevant factors since its earliest rulemaking under the CAFE program, (citations omitted). Moreover, NHTSA itself believes Congress was cognizant of safety

IPI's comment about monetization of climate and pollution-related deaths and other welfare impacts, the social cost of carbon and criteria pollutant damages estimates are intended to account for these impacts, and are considered both as part of the cost-benefit analysis and under the environmental implications aspect of the need of the U.S. to conserve energy. Given that the decision about what standards are "maximum feasible" is made by considering all of the factors, it is therefore less relevant under which factor a given issue is considered, so long as it is appropriately considered. To the extent that IPI disagrees with those estimated valuations, Section VI discusses comments on those topics and the agencies' responses.

Based on the above, NHTSA continues to believe that its interpretation of economic practicability is reasonable. Section VIII.B.4 will discuss how NHTSA has considered and balanced economic practicability for this final rule, and also respond to comments that addressed the NPRM's application of economic practicability to the information before the agency at that time.

(3) *The effect of other motor vehicle standards of the Government on fuel economy*

"The effect of other motor vehicle standards of the Government on fuel economy" involves analysis of the effects of compliance with emission, safety, noise, or damageability standards on fuel economy capability and thus on average fuel economy. In many past CAFE rulemakings, NHTSA has said that it considers the adverse effects of other motor vehicle standards on fuel economy. It said so because, from the CAFE program's earliest years²⁵⁷⁹ until recently, the effects of such compliance on fuel economy capability over the history of the CAFE program have been negative ones. For example, safety standards that have the effect of increasing vehicle weight thereby lower fuel economy capability, thus decreasing the level of average fuel economy that NHTSA can determine to be feasible. In the analyses for both the NPRM and this final rule, NHTSA has considered the additional weight that it estimates would be added in response to new safety standards during the rulemaking timeframe.²⁵⁸⁰ NHTSA has also accounted for EPA's "Tier 3" standards for criteria pollutants in its estimates of technology effectiveness in both the NPRM and final rule analyses.²⁵⁸¹

NHTSA discussed in the NPRM whether to consider EPA's CO₂ standards as an "other motor vehicle standard of the Government" among the other regulations typically considered, and if so, how. NHTSA explained that in the 2012 final rule establishing CAFE standards for MYs 2017-2021, NHTSA recognized that "To the extent the GHG standards result in increases

issues when it enacted the CAFE program. As evidence, NHTSA discusses a congressional report that dealt with the safety consequences of a downsized fleet of cars which had been considered by Congress during its enactment of the CAFE program.").

²⁵⁸⁰ PRIA, Chapter 5; FRIA, Section 5.

²⁵⁸¹ PRIA, Chapter 6; FRIA, Section 6.

in fuel economy, they would do so almost exclusively as a result of inducing manufacturers to install the same types of technologies used by manufacturers in complying with the CAFE standards.”²⁵⁸² NHTSA concluded in 2012 that “no further action was needed” because “the agency had already considered EPA’s [action] and the harmonization benefits of the National Program in developing its own [action].”²⁵⁸³

In the NPRM, NHTSA considered the issue afresh, and determined that it was clear based on a purely textual analysis of the statutory language that EPA’s CO₂ standards applicable to light-duty vehicles are literally “other motor vehicle standards of the Government,” in that they are standards set by a Federal agency that apply to motor vehicles. Basic chemistry makes fuel economy and tailpipe CO₂ emissions two sides of the same coin, as discussed at length above, and when two agencies functionally regulate both (because when regulating fuel economy, CO₂ emissions are necessarily also regulated, and vice versa), it would be absurd not to link the standards.²⁵⁸⁴ The global warming potential of N₂O, CH₄, and HFC emissions are not closely linked with fuel economy, but neither do they affect fuel economy capabilities. Simply concluding that EPA’s CO₂ standards *were* “other motor vehicle standards of the Government,” however, did not answer *how* should NHTSA should consider them.

NHTSA acknowledged in the NPRM that some stakeholders had previously suggested that NHTSA should implement this statutory factor by letting EPA decide what CO₂ standards are appropriate and reasonable under the CAA and then simply setting CAFE standards with reference to CO₂ stringency. NHTSA disagreed that such an approach would be a reasonable interpretation of EPCA, explaining that while EPA and NHTSA consider some similar factors under the CAA and EPCA/EISA, respectively, they are not identical, and standards that are appropriate under the CAA may not be “maximum feasible” under EPCA/EISA, and vice versa. Moreover, NHTSA explained, considering EPCA’s language in the context in which it was written, it seemed unreasonable to conclude that Congress intended EPA to dictate CAFE stringency. In fact, Congress clearly separated NHTSA’s and EPA’s responsibilities for CAFE under EPCA by giving NHTSA authority to set standards and EPA authority to measure and calculate fuel economy. If Congress had wanted EPA to set CAFE standards, it could have given that authority to EPA in EPCA or at any point since Congress amended EPCA.²⁵⁸⁵

NHTSA explained that NHTSA and EPA are obligated by Congress to exercise their own independent judgment in fulfilling their statutory missions, even though both agencies’

²⁵⁸² 77 FR 62624, 62669 (Oct. 15, 2012).

²⁵⁸³ *Id.*

²⁵⁸⁴ In fact, EPA includes tailpipe CH₄, CO, and CO₂ in the measurement of tailpipe CO₂ for CO₂ compliance using a carbon balance equation so that the measurement of tailpipe CO₂ exactly aligns with the measurement of fuel economy for the CAFE compliance.

²⁵⁸⁵ The NPRM noted, for instance, that EISA was passed after the *Massachusetts v. EPA* decision by the Supreme Court. If Congress had wanted to amend EPCA in light of that decision, it would have done so at that time, but did not.

regulations affect both fuel economy and CO₂ emissions. Because of this relationship, it is incumbent on both agencies to coordinate and look to one another's actions to avoid unreasonably burdening industry through inconsistent regulations,²⁵⁸⁶ but both agencies' programs must stand on their own merits. As with other recent CAFE and CO₂ rulemakings, NHTSA explained that the agencies were continuing to do all of these things in the proposal.

With regard to standards issued by the State of California, the NPRM explained that State tailpipe standards (whether for CO₂ or for other pollutants) do not qualify as "other motor vehicle standards of the Government" under 49 U.S.C. 32902(f), and that therefore, NHTSA would not consider them as such in proposing maximum feasible average fuel economy standards. NHTSA explained that States may not adopt or enforce standards related to fuel economy standards, which are preempted under EPCA, regardless of whether EPA granted any waivers under the Clean Air Act (CAA).

NHTSA and EPA agreed in the NPRM that State tailpipe CO₂ emissions standards do not become Federal standards and qualify as "other motor vehicle standards of the Government," when subject to a CAA preemption waiver. NHTSA stated that EPCA's legislative history supports that position, as follows:

EPCA, as initially passed in 1975, mandated average fuel economy standards for passenger cars beginning with model year 1978. The law required the Secretary of Transportation to establish, through regulation, maximum feasible fuel economy standards²⁵⁸⁷ for model years 1981 through 1984 with the intent to provide steady increases to achieve the standard established for 1985 and thereafter authorized the Secretary to adjust that standard.

For the statutorily-established standards for model years 1978-1980, EPCA provided each manufacturer with the right to petition for changes in the standards applicable to that manufacturer. A petitioning manufacturer had the burden of demonstrating a "Federal fuel economy standards reduction" was likely to exist for that manufacturer in one or more of those model years and that it had made reasonable technology choices. "Federal standards," for that limited purpose, included not only safety standards, noise emission standards, property loss reduction standards, and emission standards issued under various Federal statutes, but also "*emissions standards applicable by reason of section 209(b) of [the CAA]*."²⁵⁸⁸ (Emphasis added). Critically, all definitions, processes, and required findings regarding a Federal fuel

²⁵⁸⁶ *Massachusetts v. EPA*, 549 U.S. 497, 532 (2007) ("[T]here is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency.").

²⁵⁸⁷ As is the case today, EPCA required the Secretary to determine "maximum feasible average fuel economy" after considering technological feasibility, economic practicability, the effect of other Federal motor vehicle standards on fuel economy, and the need of the Nation to conserve energy. 15 U.S.C. 2002(e) (recodified July 5, 1994).

²⁵⁸⁸ Section 202 of the CAA (42 U.S.C. 7521) requires EPA to prescribe air pollutant emission standards for new vehicles; Section 209 of the CAA (42 U.S.C. 7543) preempts state emissions standards but allows California to apply for a waiver of such preemption.

economy standards reduction were located within a single self-contained subsection of 15 U.S.C. 2002 that applied only to model years 1978-1980.²⁵⁸⁹

In 1994, Congress recodified EPCA. As part of this recodification, the CAFE provisions were moved to Title 49 of the United States Code. In doing so, unnecessary provisions were deleted. Specifically, the recodification eliminated subsection (d). The House report on the recodification declared that the subdivision was “executed,” and described its purpose as “[p]rovid[ing] for modification of average fuel economy standards for model years 1978, 1979, and 1980.”²⁵⁹⁰ It is generally presumed, when Congress includes text in one section and not in another, that Congress knew what it was doing and made the decision deliberately.

NHTSA stated in the NPRM that it had previously considered the impact of California’s Low Emission Vehicle standards in establishing fuel economy standards and occasionally has done so under the “other standards” sections.²⁵⁹¹ During the 2012 rulemaking, NHTSA sought comment on the appropriateness of considering California’s tailpipe CO₂ emission standards in this section and concluded that doing so was unnecessary.²⁵⁹² In light of the legislative history discussed above, however, NHTSA stated in the NPRM that such consideration would be inappropriate, and confirms that consideration of California’s LEV standards as among the “other standards of the Government” was inappropriate.

Commenters addressing criteria pollutant standards generally supported NHTSA’s approach in the NPRM. AFPM commented that NHTSA “must consider the effect on fuel economy of EPA’s Title II standards, including the use of catalytic converters, PM traps and other technologies that address emissions and have a fuel economy impact.”²⁵⁹³ Ford also stated that previous analyses “did not assess the impact of the criteria pollutant emission standards that were adopted subsequent to the [2012 final rule],” which Ford said “increased the challenge of meeting the fuel economy and GHG targets and should be taken into consideration.”²⁵⁹⁴ Ford stated that the NPRM appropriately included “updat[ed] core engine maps using correct, regular-grade octane test fuel,” and that it accounts for “ultra-low 2025 MY Tier 3 and LEV_{III} emissions standards [which] will require aggressive cold start strategies [that] consume additional fuel at start-up in order to rapidly heat the catalyst to an effective operating temperature, which degrades CO₂ and fuel economy performance on the FTP test [and] was not considered previously....”²⁵⁹⁵

²⁵⁸⁹ As originally enacted as part of Public Law 94-163, that subsection was designated as section 502(d) of the Motor Vehicle Information and Cost Savings Act.

²⁵⁹⁵ *Id.*

Regarding how NHTSA should consider EPA's CO₂ standards as "other motor vehicle standards of the Government," ACEEE suggested amongst its comments that, in considering EPA's CO₂ standards, "NHTSA should not weaken its program ... to compensate for ... inevitable, modest differences" between EPA's and NHTSA's programs.²⁵⁹⁶ "Indeed, to the extent that differences in the requirements of the two programs remain, it is clear that the more stringent requirement in any given respect should govern the obligations of the manufacturer."²⁵⁹⁷ AFPM commented similarly that "Although NHTSA must consider the effect of other governmental regulations, Congress intended that NHTSA would have exclusive authority over a single set of national fuel economy standards."²⁵⁹⁸ Mr. Dotson expressed his belief that "Congress was cognizant of the relationship between EPCA and the Clean Air Act when crafting EISA" and cited and discussed various types of legislative history for the proposition that EISA had not limited EPA's CAA authority, and that various legislative efforts to do so had been put forth in some fashion and had failed.²⁵⁹⁹

NHTSA agrees that while it is appropriate for NHTSA to coordinate with and look to EPA's actions to avoid unreasonably burdening industry through inconsistent regulations, it would not be appropriate for NHTSA to reduce stringency below levels it believes to be maximum feasible solely for purposes of accommodating differences between programmatic flexibilities. The 2012 final rule clearly stated that while the agencies had made efforts to align their standards, programmatic differences existed, and how manufacturers chose to rely on compliance flexibilities could affect the relative stringency of NHTSA's and EPA's standards:

We note, however, that the alignment is based on the assumption that manufacturers implement the same level of direct A/C system improvements as EPA currently forecasts for those model years, and on the assumption of PHEV, EV, and FCV penetration at specific levels. If a manufacturer implements a higher level of direct A/C improvement technology (although EPA predicts 100% of manufacturers will use substitute refrigerants by MY 2021, and the GHG standards assume this rate of substitution) and/or a higher penetration of PHEVs, EVs and FCVs, then NHTSA's standards would effectively be more stringent than EPA's. Conversely, if a manufacturer implements a lower level of direct A/C improvement technology and/or a lower penetration of PHEVs, EVs and FCVs, then EPA's standards would effectively be more stringent than NHTSA's. Several manufacturers commented on this point and suggested that this meant the standards were not aligned, because NHTSA's standards might be more stringent in some years than EPA's. This reflects a misunderstanding of the agencies' purpose. The

²⁵⁹⁷ *Id.*

²⁵⁹⁸ AFPM, NHTSA-2018-0067-12078, at 52.

²⁵⁹⁹ Dotson, EPA-HQ-OAR-2018-0283-4132, Appendix A, at A2-A23. NHTSA disagrees with the persuasiveness of the legislative history cited by Mr. Dotson, which includes floor debates, colloquys, and other similar information that does not reflect the agreement of the Congress as a whole. NHTSA looks to the language Congress actually passed and the President signed into law.

agencies have sought to craft harmonized standards such that manufacturers may build a single fleet of vehicles to meet both agencies' requirements. That is the case for these final standards. *Manufacturers will have to plan their compliance strategies considering both the NHTSA standards and the EPA standards and assure that they are in compliance with both, but they can still build a single fleet of vehicles to accomplish that goal.*²⁶⁰⁰

Thus, NHTSA has been consistent in its position that CO₂ stringency does not and should not, by itself, dictate CAFE stringency. That said, consideration of EPA's standards was inherent in development of this final rule, given that the same technologies improve fuel economy and reduce CO₂ emissions, and given that CO₂ emissions represent the majority of GHGs produced by light-duty vehicles, and given that the agencies have conducted the analysis for this rulemaking jointly. NHTSA believes that EPA's standards have been fully and appropriately considered as part of its decision on these final standards. To be clear, NHTSA did not assert in the NPRM that EISA constrained EPA's authorities under the CAA and do not disagree with that aspect of Mr. Dotson's comment.

Chemours argued that, contrary to the NPRM's statements about having considered EPA's GHG standards in developing the proposal, NHTSA had *not* adequately considered EPA's GHG standards because only the no-action alternative reflected EPA regulation of the non-CO₂ GHGs, and the analysis did not otherwise account for the non-CO₂ GHG standards.²⁶⁰¹ Chemours stated that those standards were "required, pursuant to CAA section 202(a), to address 'air pollution' from mobile sources," and that "No assessment was done as to whether such standards could be made less stringent in order to avoid the various issues identified (*e.g.*, changes in technology since the 2012 final rule, costs to consumers, the effect of 'diminishing returns,' a changed petroleum market and other factors)."²⁶⁰²

NHTSA disagrees that it was necessary for NHTSA to consider EPA's standards for non-CO₂ GHG emissions any further than as discussed above. Regulation of CH₄, N₂O, and HFCs affects fuel economy only indirectly, if at all. As explained above and in the 2012 final rule, while NHTSA recognizes that some manufacturers may choose paths to compliance with EPA's GHG standards that make their compliance with CAFE standards more challenging, the agencies previewed this possibility and stated their expectation that manufacturers could make these decisions for themselves. To the extent that Chemours is asking NHTSA to examine regulatory alternatives reflecting less stringent CAFE standards in light of changed conditions since the 2012 final rule, that is exactly what the NPRM and final rule analyses have done.

²⁶⁰⁰ 77 FR at 63054-55 (Oct. 15, 2012) (emphasis added).

²⁶⁰¹ Chemours, NHTSA-2018-0067-12018, at 25.

²⁶⁰² *Id.* at 25-26.

A number of commenters disagreed with NHTSA's explanation of how State standards need not be considered under this factor. The States and Cities commenters stated that NHTSA *was* required to consider State tailpipe standards because 49 U.S.C. 32902(f) does not specify that "Government" refers only to "Federal" government; because NHTSA had not offered compelling evidence or arguments that Congress did *not* intend NHTSA to consider State tailpipe standards; and because "case law ... states unequivocally that California's standards must be considered by NHTSA under this factor [citing *Green Mountain Chrysler's* "federalizing" language]."²⁶⁰³ The States and Cities commenters further argued that NHTSA was trying to argue simultaneously that it could not consider State standards under the "other standards" factor but *could* consider State standards "under other EPCA factors, if and when it sees fit" (citing NPRM language that technological feasibility and economic practicability are broad factors allowing NHTSA to consider elements not specifically designated by Congress).²⁶⁰⁴ The States and Cities commenters further argued, citing *Fox Television*, that NHTSA was deviating from past practice without a reasoned explanation by not specifically requesting comment in the NPRM on the fact that it was not considering California's standards as "other motor vehicle standards of the Government."²⁶⁰⁵

With regard to NHTSA's analysis of EPCA's original language for MYs 1978-80 and the 1994 positive law recodification, the States and Cities commenters stated that "NHTSA's statutory and legislative history arguments related to standards for model years 1978-1980 lack merit, as NHTSA has provided no reasonable argument that Congress meant NHTSA to consider a wider range of standards for those years than for others," and stated that the section in question "was removed from the statute because it expired, not because Congress took issue with NHTSA's consideration of California's waiver standards."²⁶⁰⁶ Mr. Dotson commented similarly that NHTSA could not rely on the 1994 positive law codification as basis to conclude that State tailpipe standards (whether for GHGs or other emissions) do not qualify as "other motor vehicle standards of the Government," because it said "without substantive change...."²⁶⁰⁷

Additionally, the States and Cities commenters stated that NHTSA could not argue that California's emissions standards are not "other motor vehicle standards of the Government" because they are preempted, because NHTSA "has no authority to decide whether or not California's standards are preempted," and "one of the reasons California's Advanced Clean Cars program is not preempted by EPCA is *because* those standards are 'other motor vehicle

²⁶⁰³ States and Cities, NHTSA-2018-0067-12018, at 71.

²⁶⁰⁴ *Id.* at 71-72.

²⁶⁰⁵ *Id.* at 72. Fox Television did not involve a rulemaking, and does not require agencies to specifically seek public comment when they deviate from past practice. In any event, by articulating in the NPRM that NHTSA was not considering California's standards as "other motor vehicle standards of the Government" the public had ample opportunity to provide comment on this issue, and commenters in fact did so as discussed above.

²⁶⁰⁶ *Id.* at 71.

²⁶⁰⁷ Dotson, EPA-HQ-OAR-2018-0283-4132, Appendix A, at A23-A24.

standards of the Government’ within the meaning of EPCA.”²⁶⁰⁸ Besides this comment, a number of comments were submitted regarding NHTSA’s statements in the NPRM about EPCA’s preemption provision and how it applied to California’s standards. Those comments have been addressed²⁶⁰⁹ as part of the separate final rule published on September 27, 2019,²⁶¹⁰ and will not be discussed further as part of this action.

NHTSA affirms that its interpretation set forth in the NPRM that “other motor vehicle standards of the Government” does not apply to State emissions standards that relate to fuel economy. NHTSA does not understand how 49 U.S.C. 32919 could be given effect if the purpose of the “other motor vehicle standards of the Government” provision is to compel their inclusion in NHTSA’s decision-making. NHTSA continues to disagree with the two district court cases suggesting that the “other motor vehicle standards of the Government” provision obviates 49 U.S.C. 32919, as explained at some length in the “One National Program” final rule preceding this regulatory action.²⁶¹¹ NHTSA refers readers to that document for more detail on this topic.

With regard to State tailpipe standards that do not directly relate to fuel economy, NHTSA continues to believe that Congress’s original direction to consider “emissions standards applicable by reason of section 209(b) of [the CAA]” applied only to CAFE standards for MYs 1978-1980, as discussed in the NPRM. NHTSA agrees that the 1994 positive law recodification was not intended to make substantive changes to EPCA; the NPRM explained that, in dropping Section 502(d), Congress made clear that that provision was executed, *and that provision expressly directed NHTSA to consider State standards that had been granted preemption waivers under CAA 209(b)*. In order for States even to have their own emissions standards for motor vehicles, California must be granted a waiver of preemption under CAA section 209(b). If Congress had intended for NHTSA to continue to consider State tailpipe standards post-MY 1980, the direction to consider emissions standards that had been granted Section 209 waivers could have been placed elsewhere in the statute. Congress did not do so.²⁶¹² While NHTSA may have considered State tailpipe standards in the past, it is not bound to do so, and NHTSA does not believe that it is unreasonable to consider those standards under technological feasibility or economic practicability *if* they are to be considered.

²⁶⁰⁸ States and Cities, NHTSA-2018-0067-12018, at 71.

²⁶⁰⁹ To the extent that any individual comment was not specifically addressed, NHTSA believes that the substance and themes of all substantive comments on EPCA preemption were addressed as part of that final rule.

²⁶¹⁰ 84 FR 51310.

²⁶¹¹ *See, e.g.*, 84 FR at 51323 (Sep. 27, 2019).

²⁶¹² The negative inference canon is logically and reasonably employed here, particularly given that, as a factual matter and as discussed further below, considering EPA’s Tier 3 standards (which are clearly “other motor vehicle standards of the Government”) effectively accounts for the technological implications of California’s LEVIII standards.

State tailpipe standards primarily affect fuel economy by requiring gasoline ICE vehicles to burn additional fuel when the engine first starts. For most gasoline engines on the road today, the majority of tailpipe NO_x, NMOG, and CO emissions occur during “cold start,” before the three-way catalyst has reached the very high temperature (*e.g.*, 900-1000°F), at which point it is able to convert (through oxidation and reduction reactions) those emissions into less harmful derivatives. By strictly limiting the amount of those emissions, tailpipe smog standards require the catalyst to be brought to temperature extremely quickly, so modern vehicles employ cold start strategies that intentionally release fuel energy into the engine exhaust to heat the catalyst to the relevant temperature as quickly as possible. The additional fuel that must be used to heat the catalyst is typically referred to as a “cold-start penalty,” meaning that vehicle’s fuel economy (over a test cycle) is reduced because the fuel consumed to heat the catalyst did not go toward the goal of moving the vehicle forward.²⁶¹³ The Autonomie work employed to develop technology effectiveness estimates for this final rule does, in fact, account for cold-start penalties.²⁶¹⁴ The Autonomie model documentation discusses the fact that cold-start penalties were derived from an EPA database of MY 2016 vehicles, which would have met both EPA and California smog standards. Moreover, EPA regulations allow manufacturers to employ LEVIII data for Tier 3 compliance. Based on all of these factors, NHTSA believes that the negative fuel economy effects of California’s tailpipe standards for smog-related emissions are reasonably represented in the analysis for the final rule, regardless of whether NHTSA was obligated by law to consider them expressly.

Ultimately, it would be illogical for NHTSA to consider legally unenforceable standards to be “other motor vehicle standards of the Government.” That is the case for State standards preempted by EPCA. While NHTSA understands that certain commenters disagree with a separate final rule that NHTSA issued concerning EPCA preemption, and the particular State standards that NHTSA considers preempted by EPCA, those issues are outside the scope of this final rule.

(4) *The need of the United States to conserve energy*

NHTSA has historically interpreted “the need of the United States to conserve energy” to mean “the consumer cost, national balance of payments, environmental, and foreign policy implications of our need for large quantities of petroleum, especially imported petroleum.”²⁶¹⁵

²⁶¹³ For more information on this, *see, e.g.*, Pihl, Josh A., *et al.*, “Development of a Cold Start Fuel Penalty Metric for Evaluating the Impact of Fuel Composition Changes on SI Engine Emissions Control,” Oak Ridge National Laboratory, 2018. Available at <https://www.osti.gov/biblio/1462896-development-cold-start-fuel-penalty-metric-evaluating-impact-fuel-composition-changes-si-engine-emissions-control>.

²⁶¹⁵ 42 FR 63184, 63188 (Dec. 15, 1977).

(a) *Consumer costs and fuel prices:*

NHTSA explained in the NPRM that fuel for vehicles costs money for vehicle owners and operators. All else equal—a critical caveat—consumers benefit from vehicles that need less fuel to perform the same amount of work. Future fuel prices are a critical input into the economic analysis of potential CAFE standards because they determine the value of fuel savings both to new vehicle buyers and to society, the amount of fuel economy that the new vehicle market is likely to demand in the absence of new standards, and they inform NHTSA about the “consumer cost...of our need for large quantities of petroleum.” In the proposal, NHTSA’s analysis relied on fuel price projections from the U.S. Energy Information Administration’s (EIA) Annual Energy Outlook (AEO) for 2017; in the final rule, on fuel price projections derived from the version of NEMS used to produce AEO 2019. Federal government agencies generally use EIA’s price projections in their assessment of future energy-related policies.

Several commenters stated that consumer costs for fuel were an important consideration. ACEEE stated that “The average U.S. household still spent nearly \$2,000 on gasoline and motor oil (directly) in 2017, making oil savings very relevant for consumers,” and argued that “Oil price volatility remains a threat to U.S. consumers and businesses—the price of crude oil has more than doubled since 2016, belying the theoretical suggestion in the notice that conditions for oil price shocks no longer exist,” suggesting that further fuel efficiency improvements were necessary to protect consumers.²⁶¹⁶ NESCAUM commented that prior analyses had suggested that consumers would save \$6,000 on net, after paying more for their vehicles upfront, and that the proposal would cost consumers more in fuel.²⁶¹⁷ Both NESCAUM and the States and Cities commenters stated that higher fuel costs would disproportionately affect low-income consumers, who spend a higher share of their income on fuel costs.²⁶¹⁸ The Congressional Tri-Caucus commented that “As we see oil prices rising again, it makes no sense for DOT to roll back these standards.”²⁶¹⁹ The States and Cities commenters argued that increased gas expenditures would result “in negative economy-wide effects” for many years “given that cars sold in the model years for which NHTSA proposes to freeze standards will, according to the Agencies, be on the road for decades,” and stated that “NHTSA’s analysis is arbitrary and capricious because it entirely fails to consider how the Proposed Rollback would impact consumers and the economy as a whole due to increased gasoline expenditures.”²⁶²⁰ The States and Cities commenters further argued that NHTSA was incorrect in the NPRM when it interpreted “the relevant question for the need of the U.S. to conserve energy is not whether there will be *any* movement in prices but whether that movement will be sudden and large,”²⁶²¹ and cited *State*

Farm to say that NHTSA had “failed to consider an important aspect of the problem” by “failing to analyze the likely impact of even moderate future increases and volatility in fuel prices.”²⁶²²

A number of commenters addressed consumer willingness to pay more money upfront in order to save money on fuel costs. Many of these comments are addressed in Section VI.C as part of the discussion of how sales are modeled. More specifically in the context of how NHTSA interprets the need of the U.S. to conserve energy, IPI commented that NHTSA was incorrect that “consumers’ need to save money is now ‘less urgent’ and no longer supports a strong overall need to conserve energy. The agencies assert that past rulemakings were overly and paternalistically focused on ‘myopia.’ This statement ignores all the other pathways through which the 2012 standards benefit consumers’ need to save money, including by correcting informational asymmetries, attention costs, and other informational failures; positional externalities; and various other supply-side and demand-side explanations for consumers’ inability to achieve in an unregulated market the level of fuel economy that they desire. These components of the national need to conserve energy are discussed at length throughout these comments, and were specifically considered by the agencies in the 2012 rule.”²⁶²³

Several commenters disagreed with NHTSA’s suggestion in the NPRM that increasing U.S. production and exports reduced volatility in the oil market. Securing America’s Energy Future stated that “...recent events are an important validation of public policies that support long-term goals like efficiency and fuel diversity. Indeed, in the absence of fuel-efficiency standards, global oil price volatility would likely render the country even more exposed to oil price shocks than it is currently.”²⁶²⁴ Mr. Bordoff, IPI, the States and Cities commenters, and UCS all commented that the oil market is global, so increasing U.S. production does not prevent price shocks that occur due to non-U.S. events or circumstances. Mr. Bordoff stated that “In a globalized oil market, the consequence of a supply disruption anywhere is a price increase everywhere—regardless of how much oil the U.S. imports.”²⁶²⁵ UCS made similar comments.²⁶²⁶ Mr. Bordoff further commented that U.S. gasoline prices still follow the fluctuations in global crude oil prices regardless of the U.S. oil import/export balance,²⁶²⁷ and stated that “Gasoline prices at the pump are especially sensitive to changes in the global crude oil price due to the relatively low level of fuel taxation [in the U.S.] compared to other OECD countries.”²⁶²⁸ Mr. Bordoff stated that gas price spikes are still possible due to ongoing geopolitical challenges in major oil producing areas, and concluded that “Continuing with planned fuel economy increases through CAFE standards is one effective way to reduce the oil intensity of the economy and mitigate the adverse impact of future oil price increases on

American drivers.”²⁶²⁹ The States and Cities commenters cited to and echoed Mr. Bordoff’s comments on this point.²⁶³⁰ CARB commented that the proposal had relied on AEO 2017, which reflected fuel prices that still assumed the augural standards remained in place, but that AEO 2018 assumes “no new fuel efficiency standard” and held fuel economy flat after 2021, and showed fuel prices would be higher.²⁶³¹

Mr. Bordoff also commented that the future of shale oil in the U.S. was uncertain, and therefore increased U.S. oil production was not a basis on which to assume future global price stability.²⁶³² Mr. Bordoff argued that “Although shale oil is more responsive to price changes than conventional supply, it cannot serve as a swing supplier to stabilize oil markets in the way true spare capacity (held by Saudi Arabia) can. It takes at least 6-12 months for U.S. shale to respond to price changes.”²⁶³³ Bordoff continued, stating that “For example, although shale oil is more more responsive to oil prices, oil prices still plunged below \$30 per barrel at the start of 2016 and soared to \$80 per barrel earlier this year. Shale oil could not swing quickly enough to stabilize markets. This role fell to OPEC instead in both cases, first to put a floor under prices by cutting supply and, more recently, to provide relief by ramping up production.”²⁶³⁴ Bordoff further commented that political or popular pressures due to environmental concerns may significantly increase the cost and/or difficulty of expanding shale infrastructure,²⁶³⁵ and that even disregarding uncertainty in supply, ongoing uncertainty in demand (both U.S. and abroad) also contributed to global price uncertainty.²⁶³⁶

NHTSA agrees with commenters that consumer costs for fuel are relevant to the need of the U.S. to conserve energy. NHTSA also agrees that future fuel prices are uncertain, and that shale oil development in the U.S. is (1) still proceeding and subject to uncertainty, (2) very different from traditional sources like Saudi Arabia, and (3) not enough, by itself, to preclude any possibility of major swings in future global oil prices. That said, NHTSA continues to believe that U.S. shale development may reduce the effects of global price swings due to events and situations outside of our borders. Shale represents a large, new, relatively-geopolitically-stable oil supply source, and traditional oil producers appear to understand that stabilizing prices below the price at which shale production starts to ramp up faster helps those traditional producers take market advantage of their lower cost of production.²⁶³⁷ The net effect of this, for American

²⁶³⁷ Since 1995, EIA data indicates that OPEC production roughly stabilized in late 2016 and has either remained steady or fallen since then. *See* https://www.eia.gov/opendata/qb.php?category=1039874&sdid=STEO.PAPR_OPEC.M. *See also* Ilya Arkhipov, Will Kennedy, Olga Tanas, and Grant Smith, “Putin Dumps MBS to Start a War on America’s Shale Oil Industry,”

drivers, should be greater fuel price stability. NHTSA also continues to believe that, for purposes of considering consumer cost of fuel as part of the need of the U.S. to conserve energy, the fact that Americans' gasoline costs might be minutely lower under more stringent CAFE standards and minutely higher under comparatively less stringent CAFE standards is not dispositive by itself. There is some tolerance in the market for some amount of fluctuation in fuel prices, as evidenced by the discussion in Section VI. Slow increases in fuel prices are relatively easy for households to absorb; sharp increases are more difficult.

Commented [A17]: Why?

Increases in CAFE stringency reduce the effects of all types of increases in fuel prices, at least to the extent that people can buy new cars and trucks, but as discussed below in Section VIII.B.4, fuel costs and per-vehicle costs balance against one another for many buyers. With respect to relatively low U.S. gasoline taxes creating more pass-through effects of global oil price fluctuations, that would be true regardless of stringency. Broadly speaking, while consumer fuel costs are an important consideration of the need of the U.S. to conserve energy, at this time NHTSA believes, as discussed in Section VI, that American consumers generally understand fuel costs and their tolerance for fluctuations, and tend to purchase vehicles accordingly. Requiring consumers to save more fuel over the longer term by spending more money upfront on new vehicle purchases may involve more tradeoffs than suggested in prior rulemakings, and this rulemaking seeks to keep these possible tradeoffs in mind.

(b) *National balance of payments:*

As the NPRM explained, the need of the United States to conserve energy has historically included consideration of the “national balance of payments” because of concerns that importing large amounts of oil created a significant wealth transfer to oil-exporting countries and left the U.S. economically vulnerable.²⁶³⁸ As recently as 2009, nearly half the U.S. trade deficit was driven by petroleum,²⁶³⁹ yet this concern has largely laid fallow in more recent CAFE actions, arguably in part because other factors besides petroleum consumption have since played a bigger role in the U.S. trade deficit. Given recent significant increases in U.S. oil production and corresponding decreases in oil imports, this concern seems likely to remain fallow for the foreseeable future.²⁶⁴⁰ Increasingly, changes in the price of fuel have come to represent transfers

March 7, 2020, Bloomberg News, *available at* <https://www.bloomberg.com/news/articles/2020-03-07/putin-dumps-mbs-to-start-a-war-on-america-s-shale-oil-industry> (describing the collapse of the OPEC+ coalition).

²⁶³⁸ See 42 FR 63184, 63192 (Dec. 15, 1977) “A major reason for this need [to reduce petroleum consumption] is that the importation of large quantities of petroleum creates serious balance of payments and foreign policy problems. The United States currently spends approximately \$45 billion annually for imported petroleum. But for this large expenditure, the current large U.S. trade deficit would be a surplus.”

²⁶³⁹ See *Today in Energy: Recent improvements in petroleum trade balance mitigate U.S. trade deficit*, U.S. Energy Information Administration (July 21, 2014), <https://www.eia.gov/todayinenergy/detail.php?id=17191>.

²⁶⁴⁰ For an illustration of recent increases in U.S. production, see, e.g., *U.S. crude oil and liquid fuels production, Short-Term Energy Outlook*, U.S. Energy Information Administration (June 2018), <https://www.eia.gov/outlooks/steo/images/fig13.png>. While it could be argued that reducing oil consumption frees up more domestically-produced oil for exports, and thereby raises U.S. GDP, that is neither the focus of the CAFE

between domestic consumers of fuel and domestic producers of petroleum rather than gains or losses to foreign entities. NHTSA explained in the NPRM that some commenters have lately raised concerns about potential economic consequences for automaker and supplier operations in the U.S. due to disparities between CAFE standards at home and their counterpart fuel economy/efficiency and CO₂ standards abroad. NHTSA finds these concerns more relevant to technological feasibility and economic practicability than to the national balance of payments. Moreover, to the extent that an automaker decides to globalize a vehicle platform to meet more stringent standards in other countries, that automaker would comply with United States's standards and additionally generate overcompliance credits that it can save for future years if facing compliance concerns, or sell to other automakers. While CAFE standards are set at maximum feasible rates, efforts of manufacturers to exceed those standards are rewarded not only with additional credits but a market advantage in that those consumers who place a large weight on fuel savings will find such vehicles that much more attractive.

Several commenters addressed how much oil the U.S. imports, and the assumptions about imports in the NPRM analysis. Securing America's Energy Future commented that "Because there are no readily available substitutes to oil in the U.S. transportation sector, volatile crude oil and petroleum product prices represent an enduring threat to the U.S. economy."²⁶⁴¹ ACEEE commented that overall U.S. oil imports are higher now than they were in 1975, and nearly as high as they were in 2012, and also stated that compared to a small overall trade surplus in 1975, "the U.S. now runs a large overall trade deficit."²⁶⁴² The States and Cities commenters made a similar point, arguing that the U.S. still imports large amounts of petroleum; that imports made up about 25 percent of total U.S. oil consumption in 2017; and that EIA indicates that "imports as a share of oil consumption in the United States are only about 10% lower today as compared to 1975, and we are producing the same amount of crude oil domestically today as we were in 1970."²⁶⁴³ IPI stated that EIA analysis shows that the "U.S. will continue to import crude oil through 2050 and 'remains a net importer of petroleum and other liquids on an energy basis.'"²⁶⁴⁴ CARB disagreed that the U.S. was projected to become a net petroleum exporter, and stated that even if it were, the rollback would have negative effects on the U.S., because (1) it ignores short-run damages caused by increased oil consumption and imports; (2) relies on projections of net imports of oil which also do not take account of the effects of the proposed rule; and (3) is not supported by the evidence.²⁶⁴⁵

program nor consistent with Congress' original intent in EPCA. EIA's Annual Energy Outlook (AEO) series provides midterm forecasts of production, exports, and imports of petroleum products, and is available at <https://www.eia.gov/outlooks/aeo/>.

²⁶⁴⁵ CARB, NHTSA-2018-0067-11873, at 317.

Regarding assumptions about oil imports in the NPRM analysis, the States and Cities commented that in 2016 the agencies had assumed that “90% of fuel savings from existing standards would lead directly to a reduction in imported oil,” and argued that the NPRM analysis had ignored that previous assumption and “la[id] great emphasis on the fact that ‘oil imports have declined while exports have increased’ since 2005.”²⁶⁴⁶ IPI argued that the NPRM analysis was internally inconsistent, assuming in NHTSA’s need of the nation discussion that “additional gasoline consumption will be entirely domestic,” while “upstream emissions calculations assume that 95% of increased consumption will either be from foreign refining or from foreign crude imports,” and suggested that this inconsistency was purposeful to make the NPRM analysis look more favorable to the proposal.²⁶⁴⁷ ACEEE commented that “The EIA AEO side cases suggest that reduced oil demand will primarily reduce oil imports, thus improving the overall balance of trade regardless of the narrow balance of trade in petroleum.”²⁶⁴⁸

Regarding the effects on the U.S. economy of increasing U.S. oil production, Mr. Morris agreed with the NPRM’s suggestion that U.S. self-sufficiency in petroleum supply meant that higher consumer payments for fuel under less-stringent CAFE standards would be transfers within the U.S. economy, and stated that “[a]t that point, the initial purpose of EPCA is entirely obviated.”²⁶⁴⁹ The States and Cities commenters, in contrast, argued that focusing on this effect meant that NHTSA essentially claims that increasing revenues of oil companies—which report annual profits in the billions—is an even trade-off for adding cost pressures and oil-price shock exposure to American households.²⁶⁵⁰ The States and Cities commenters stated that “...this assertion ignores the negative economic impacts that would result from increasing the cost burden on oil consumers,” and was “...so implausible that it could not be ascribed to a difference of view or the product of agency expertise,” citing *State Farm*, 463 U.S. at 43.²⁶⁵¹

As discussed above, NHTSA agrees that oil is a global commodity. Living in a globalized economy necessarily means that supply disruptions (and thus, price effects) can come from a great variety of sources—this was why the CAFE program was created, in recognition of this risk. Increasing U.S. energy independence reduces this risk. There are two ways to increase petroleum independence: to use less petroleum, and to produce more of our own petroleum and use less petroleum purchased from abroad. Both approaches work, and both are being followed today.

NHTSA also agrees that the Draft TAR text describes the analytical assumption that for every gallon of fuel not consumed as a result of more stringent standards, imported crude would be reduced by 0.9 gallons. The Draft TAR stated that this assumption was based on “changes in

²⁶⁵¹ *Id.*

U.S. crude oil imports and net petroleum products in the AEO 2015 Reference Case in comparison [*sic*] the Low (i.e., Economic Growth) Demand Case,” and also on a 2013 paper by Paul Leiby which “suggests that ‘Given a particular reduction in oil demand stemming from a policy or significant technology change, the fraction of oil use savings that shows up as reduced U.S. imports, rather than reduced U.S., supply, is actually quite close to 90 percent, and probably close to 95 percent.’”²⁶⁵²

EIA data clearly states that while the U.S. still relies on oil imports, it is producing an increasingly large share of the petroleum it consumes.²⁶⁵³ In 2018, domestic petroleum production made up 86 percent of domestic consumption, while imports made up 11 percent. EIA data also clearly states that U.S. reliance on petroleum imports peaked in 2005 and has declined since then, and that the import-percentage-of-consumption in 2018 was the lowest it has been since 1957—this despite the fact that overall U.S. petroleum consumption has increased significantly over that time period as the on-road fleet has grown and VMT (both individual and collective) has increased. Of the 11 percent of oil consumed that was imported, 43 percent came from Canada, and 16 percent came from Persian Gulf countries. AEO 2019 states that under its Reference case assumptions, which it describes as a “best assessment” and “a reasonable baseline case,”²⁶⁵⁴ the U.S. remains projected to become a net exporter of petroleum liquids by 2020.²⁶⁵⁵ During several weeks in 2019, the U.S. also exported more oil than it imported.²⁶⁵⁶

U.S. Census data indicate that the U.S. balance of trade has generally grown over time, although it has fluctuated since peaking in 2006.²⁶⁵⁷ U.S. Census data further indicate that the U.S. petroleum balance of trade, in particular, has fluctuated over time, peaking in 2008 at roughly -\$386 million and decreasing to -\$50 million in 2018. 2019 trends demonstrate further decreases. In percentage terms, petroleum trade as a percentage of total trade went from roughly 52 percent in 1992 (the earliest year for which Census appears to have data online), to 47 percent in 2008, to less than 6 percent in 2018. In terms of national balance of payments, this is fairly clear evidence that petroleum has decreased rapidly as part of the problem. Part of this is due to improvements in fleet fuel economy over time, and part is due to increases in U.S. production, particularly in the last several years.

NHTSA notes also that the Draft TAR previewed the possibility of this outcome, discussing the “Shale Oil Revolution” and the fact that “[t]he recent economics literature on

whether oil shocks are the threat to economic stability that they once were is mixed.”²⁶⁵⁸ The Draft TAR stated that because of increased U.S. shale oil production, “The resulting decrease in foreign imports...effectively permits U.S. supply to act as a buffer against artificial or other supply restrictions (the latter due to conflict or a natural disaster, for example).”²⁶⁵⁹

Since the Draft TAR was issued, U.S. shale production has developed even further, and U.S. petroleum imports have continued to fall. If more oil is being produced in the U.S., and more of domestic consumption comes from domestic production, then even though oil is a global commodity and thus subject to price changes resulting from non-U.S. events, the U.S. economy is inherently better off. When money moves around within the U.S. instead of having to leave the U.S., and everyone’s needs are being met, U.S. citizens are better off when things outside the U.S. go wrong—this is what NHTSA means when it refers to within-U.S. transfers not being a bad thing as compared to greater reliance on imports for consumption needs. To the extent that some commenters find within-U.S. transfers problematic because they increase U.S. oil company revenues without reducing fuel cost burdens on consumers, NHTSA notes that, as discussed above, consumers seem willing and able to tolerate some amount of fuel price increases and fluctuation risk, as evidenced by their purchasing decisions. Prices may still fluctuate, but shortages may foreseeably be reduced.

The Draft TAR stated that “despite continuing uncertainty about oil market behavior and outcomes and the sensitivity of the U.S. economy to oil shocks, it is generally agreed that it is beneficial to reduce petroleum fuel consumption from an energy security standpoint. It is not just imports alone, but both imports and consumption of petroleum from all sources and their role in economic activity, that may expose the U.S. to risk from price shocks in the world oil price. Reducing fuel consumption reduces the amount of domestic economic activity associated with a commodity whose price depends on volatile international markets.” NHTSA continues to agree with these statements, but cannot ignore the fact that increased U.S. petroleum production represents the other side of the coin. Again, both national balance of payments and energy security can be improved on both the supply side and the demand side. While today’s final rule continues to improve on the demand side by setting standards that continue to push CAFE levels upward, it also recognizes that supply side improvements are playing a role.

(c) *Environmental implications*

The NPRM explained that higher fleet fuel economy can reduce U.S. emissions of CO₂ as well as various other pollutants by reducing the amount of oil that is produced and refined for the U.S. vehicle fleet, but can also increase emissions by reducing the cost of driving, which can result in increased vehicle miles traveled (i.e., the rebound effect). Thus, the net effect of more stringent CAFE standards on emissions of each pollutant depends on the relative magnitudes of its reduced emissions in fuel refining and distribution and increases in its emissions from vehicle

²⁶⁵⁸ See Draft TAR at 10-30 – 10-33.

²⁶⁵⁹ Draft TAR at 10-31.

use. Fuel savings from CAFE standards also necessarily result in lower emissions of CO₂, the main gas emitted as a result of refining, distribution, and use of transportation fuels. Reducing fuel consumption directly reduces CO₂ emissions because the primary source of transportation-related CO₂ emissions is fuel combustion in internal combustion engines.

NHTSA has considered environmental issues, both within the context of EPCA and the context of the National Environmental Policy Act (NEPA), in making decisions about the setting of standards since the earliest days of the CAFE program. As courts of appeal have noted in three decisions stretching over the last 20 years,²⁶⁶⁰ NHTSA defined “the need of the United States to conserve energy” in the late 1970s as including, among other things, environmental implications. In 1988, NHTSA included climate change concepts in its CAFE notices and prepared its first environmental assessment addressing that subject.²⁶⁶¹ It cited concerns about climate change as one of its reasons for limiting the extent of its reduction of the CAFE standard for MY 1989 passenger cars.²⁶⁶² Since then, NHTSA has considered the effects of reducing tailpipe emissions of CO₂ in its fuel economy rulemakings pursuant to the need of the United States to conserve energy by reducing petroleum consumption.

Many commenters addressed the environmental implications of CAFE standards and the proposal. ACEEE stated that “The environmental need to save energy is much greater than we realized in 1975,” and that “The notice argues that since improved standards will not by themselves solve global warming, they are not necessary. That logic would equally suggest that since no one soldier would win a war, we should never deploy any troops. No one measure will solve global warming....vehicle standards have been the most important.”²⁶⁶³ The Harvard environmental law clinic commenters similarly stated that “It is illogical to argue against taking a single step on the basis that a single step is insufficient to reach one’s goal,” and commented that it was unreasonable for the DEIS to state that “[t]he emission reductions necessary to keep global emissions within this carbon budget could not be achieved solely with drastic reductions in emissions from the U.S. passenger car and light truck fleet.”²⁶⁶⁴ UCS also argued that with respect to the environmental implications of the standards, NHTSA’s “argument that the augural standards would only limit global warming by 0.02 degrees C in 2100 actually *supports* the need to maintain the standards. That a single U.S. policy could make that much difference in limiting global warming is, in fact, quite significant.”²⁶⁶⁵

²⁶⁶⁵ UCS, NHTSA-2018-0067-12039, at 7.

The States and Cities commenters objected to NHTSA's consideration in the NPRM of "whether rapid ongoing increases in CAFE stringency . . . can sufficiently address climate change to merit their costs," arguing that NHTSA had "completely disregard[ed] environmental costs" contrary to NHTSA's own long-standing approach to CAFE standards.²⁶⁶⁶ The States and Cities commenters then framed the CO₂ impacts of the proposal in tons (specifically, 7,400 million metric tons additional CO₂ emitted by 2100 as compared to the augural standards) and argued that "the agency effectively ignores its own findings, in a sharp and unexplained break with the agency's past practice of considering climate impacts," citing *Fox Television*, 556 U.S. at 515 and the 2010 and 2012 final CAFE rules which discussed reduced economic damages from lower climate impacts for those standards compared to their baselines.²⁶⁶⁷ IPI also argued that if NHTSA had focused on economic damages rather than fractions of degrees Celsius, "Once climate damages are fully monetized (as the agencies are required to do), it will become apparent that the proposed rollback will cause billions of dollars in climate damages. Billions of dollars lost to avoidable climate damages is not a small effect, and it very clearly is a 'destructive and wasteful' effect."²⁶⁶⁸ CARB also argued that the NPRM had "wholly fail[ed] to analyze the economic effects of the climate change and public health implications of the rollback," stating that [t]he Agencies assert these are insignificant, but that is only because the Agencies' projections of climate change are so extreme. An appropriate analysis of a proposal that speeds progress toward such a calamitous condition must acknowledge and analyze the expected effects."²⁶⁶⁹

The States and Cities commenters also argued that NHTSA had not explained what the NPRM's definition of "conservation" as meaning "avoid[ing] wasteful or destructive use" "actually means and how it changes the agency's past practice of considering environmental impacts," citing *State Farm*, 463 U.S. at 43, and *Fox Television*, 556 U.S. at 515.²⁶⁷⁰

Regarding non-climate impacts, IPI commented that the NPRM "only briefly mention[ed] the possible effects on other emissions without detailing any of the myriad non-climate public health and welfare consequences from pollution associated with petroleum production and combustion for motor vehicles."²⁶⁷¹ The States and Cities commenters similarly stated that "NHTSA's evaluation of this factor fails to include any analysis of environmental costs related to air quality," and that the NPRM/DEIS analysis substantially understates the actual impacts of the Proposed Rollback on criteria air pollutants (such as NO_x and PM) and air toxics (such as benzene), making it inappropriate to rely upon."²⁶⁷²

NHTSA agrees that the NPRM considered environmental implications of the standards somewhat differently from past rulemaking discussions. The 2012 final rule, for example, stated that “[t]he need of the nation to conserve energy has long operated to push the balancing toward more stringent standards,” and asked “[i]n this final rule, then, the question raised by this factor, combined with technological feasibility, becomes ‘how stringent can NHTSA set standards before economic practicability considerations intercede?’”²⁶⁷³ The NPRM discussed the dictionary definition of “to conserve,” tentatively concluded that thousandths of a degree centigrade in 2100 did not rise to the level of being “wasteful,” and suggested that ultimately “we no longer view the need of the U.S. to conserve energy as nearly infinite.”²⁶⁷⁴ This is an evolution in interpretation that was expressly acknowledged in the NPRM—the words “we no longer view” clearly indicate acknowledgement of a change in view, i.e., interpretation. The NPRM’s climate findings were not ignored, they were directly examined and discussed at 83 FR 43215-16 in the context of NHTSA’s interpretation of their significance. The NPRM also discussed overall costs and benefits and net benefits in the context of the proposed maximum feasible determination, and the cost of carbon emissions was included in those values. This final rule similarly directly examines and discusses the analytical findings below.

Moreover, contrary to commenters’ statements that NHTSA did not acknowledge that its interpretation of the effect of the “need of the U.S. to conserve energy” factor was changing, or that the balancing of factors was different, the NPRM directly stated that:

NHTSA well recognizes that the decision it proposes to make in today’s NPRM is different from the one made in the 2012 final rule that established standards for MY 2021 and identified ‘augural’ standard levels for MYs 2022-2025. Not only do we believe that the facts before us have changed, but we believe that those facts have changed sufficiently that the balancing of the EPCA factors and the other considerations must also change. The standards that we are proposing today reflect that balancing.²⁶⁷⁵

²⁶⁷³ 77 FR at 63038-39.

²⁶⁷⁴ 83 FR at 43215-16.

²⁶⁷⁵ 83 FR at 43213. *See also* 83 FR at 43226 (“In the 2012 final rule..., NHTSA stated that ‘maximum feasible standards would be represented by the mpg levels that we could require of the industry before we reach a tipping point that presents risk of seriously adverse economic consequences.’ [citation omitted] However, the context of that rulemaking was meaningfully different from the current context. At that time, NHTSA understood the need of the U.S. to conserve energy as necessarily pushing the agency toward setting stricter and stricter standards. Combining a then-paramount need of the U.S. to conserve energy with the perception that technological feasibility should no longer be seen as a limiting factor, NHTSA then concluded that only significant economic harm would be the basis for controlling the pace at which CAFE stringency increased over time. Today, the relative importance of the need of the U.S. to conserve energy has changed ... a great deal even since the 2012 rulemaking. [T]he need of the U.S. to conserve energy may no longer disproportionately outweigh other statutorily-mandated considerations such as economic practicability—even when considering fuel savings from potentially more-stringent standards.”).

NHTSA believes that this is clear acknowledgement of the differences in interpretation and the effect of those differences on policy decisions.

That said, NHTSA agrees (indeed, has always agreed) with commenters that environmental implications exist as a result of changes in CAFE stringency. While CO₂ emissions will be higher under this final rule than if NHTSA had determined that the augural standards were maximum feasible, they will be lower than they would have been under the proposal—for the “standard setting” runs, which are what NHTSA looks at for assistance in determining maximum feasible standards, NHTSA estimates that, accounting for both tailpipe and upstream emissions, CO₂ emissions in 2050 under the final standards will total 1,134 mmt, as compared to 1,149 mmt under the proposed standards, or 1,020 mmt under the augural standards. According to the Final EIS, which uses a “real-world” analysis that incorporates models and modeling approaches that permit the agency to take a hard look at the potential environmental impacts of the rule,²⁶⁷⁶ NHTSA estimates that these amounts of CO₂ emissions would lead to the following global temperature, sea level, and ocean acidification effects²⁶⁷⁷:

²⁶⁷⁶ See *Kleppe v. Sierra Club*, 427 U.S. 390, 410, n. 21 (1976).

²⁶⁷⁷ As discussed in Section 5.3.1 of the FEIS, NHTSA used the Global Change Assessment Model (GCAM) Reference scenario to represent the No Action Alternative (Alternative 0) in the modeling runs used to create [Table VIII-1 Table 1-1](#). The GCAM Reference Scenario is based on a set of assumptions about drivers such as population, technology, and socioeconomic changes, in the absence of global action to mitigate climate change. It can be described as a “business-as-usual” scenario. NHTSA also conducted an analysis in Chapter 8 of the FEIS using the GCAM6.0 scenario, which assumes a moderate level of global GHG reductions and corresponds to stabilization, by 2100, of total radiative forcing and associated CO₂ concentrations at roughly 678 ppm. Several commenters argued that NHTSA presented climate results in the NPRM/DEIS in the context of a “doomsday scenario,” in which no actions at all are taken to mitigate carbon emissions, but NHTSA emphasizes that this is simply the GCAM Reference Scenario, which is a reasonable scenario to run given that GCAM is a widely accepted climate model. Running the analysis using the GCAM Reference Scenario and GCAM6.0 Scenario results in different absolute values for the climate variables presented in this table and Table 8.6.4-1 of the FEIS, but again, this is because of the underlying scenarios, which reflect very different levels of global action. When the differences in levels of global action are accounted for, the relative impact of each action alternative as compared to the No Action Alternative is very similar. Thus, regardless of what GCAM scenario the agencies consider regarding global action to mitigate climate change, it is still meaningful to draw conclusions about the relative impacts of the alternatives, because the alternatives are what is within the agencies’ authority to affect.

NHTSA understands that some commenters view climate change as an imminent existential threat. NHTSA does not agree, however, that Congress intended for NHTSA to set aside other statutory factors in determining what CAFE standards would be maximum feasible. Otherwise, NHTSA believes that Congress would have amended EPCA through EISA in 2007, when climate change was well understood, or taken another act to remove economic practicability as a consideration. Even the maximum feasible discussion for the 2012 final rule stated that

We recognize that higher standards would help the need of the nation to conserve more energy..., but based on our analysis and the evidence presented by the industry, we conclude that higher standards would not represent the proper balancing for MYs 2017-2025 cars and trucks. [footnote omitted] We conclude that the correct balancing recognizes economic practicability concerns as discussed above, and sets standards at the levels that the agency is promulgating in this final rule for MYs 2017-2021 and presenting for MYs 2022-2025.²⁶⁷⁸

The footnote following the last sentence quoted above further stated that “We underscore that the agency’s decision regarding what standards would be maximum feasible for MYs 2017-2025 is made with reference to the rulemaking time frame and the circumstances of this final rule. Each CAFE rulemaking (indeed, each stage of any given CAFE rulemaking) presents the agency with new information that may affect how we balance the relevant factors.”²⁶⁷⁹ NHTSA has been consistent over time, despite commenters’ suggestions to the contrary, that maximum feasible is a balancing of factors; that all factors must be considered; and that information before the agency may change how the agency both understands and balances the statutory factors.

With regard to criteria and toxic air pollutant emissions, NHTSA agrees with commenters that the NPRM discussion of environmental implications did not specifically identify these emissions, but notes that air quality issues were discussed in a variety of places in the NPRM, DEIS, and PRIA, and that the monetized effects of air quality impacts were included in the overall cost-benefit analysis which informed NHTSA’s balancing of factors, as discussed above. To the extent that commenters disagreed with the values or the agency’s air quality analyses, those topics will be addressed in Section VII and VIII and in the FEIS. NHTSA has considered all of these findings along with other factors, as discussed below.

(d) Foreign policy implications

In the NPRM, NHTSA explained that U.S. consumption and imports of petroleum products impose costs on the domestic economy that are not reflected in the market price for crude petroleum or in the prices paid by consumers for petroleum products such as gasoline.

²⁶⁷⁸ 77 FR at 63055.

²⁶⁷⁹ *Id.*, fn. 1275.

These costs include (1) higher prices for petroleum products resulting from the effect of U.S. oil demand on world oil prices, (2) the risk of disruptions to the U.S. economy caused by sudden increases in the global price of oil and its resulting impact of fuel prices faced by U.S. consumers, and (3) expenses for maintaining the strategic petroleum reserve (SPR) to provide a response option should a disruption in commercial oil supplies threaten the U.S. economy, to allow the U.S. to meet part of its International Energy Agency obligation to maintain emergency oil stocks, and to provide a national defense fuel reserve.²⁶⁸⁰ Higher U.S. consumption of crude oil or refined petroleum products increases the magnitude of these external economic costs, thus increasing the true economic cost of supplying transportation fuels above the resource costs of producing them. Conversely, *reducing* U.S. consumption of crude oil or refined petroleum products (by reducing motor fuel use) can reduce these external costs.

The NPRM stated that while these costs are considerations, the United States has significantly increased oil production capabilities in recent years to the extent that the U.S. is currently producing enough oil to satisfy nearly all of its energy needs and is projected to continue to do so or become a net energy exporter. This has added new stable supply to the global oil market and reduced the urgency of the U.S. to conserve energy. The NPRM referred readers to the balancing discussion for more detail on this issue.

Securing America's Energy Future commented that continuing to raise stringency would be good for energy security, spur innovation, and "advance the administration's energy dominance agenda."²⁶⁸¹ CARB argued that the proposal would "significantly diminish U.S. energy security," "...contrary to the President's recent executive order to promote national security, and contrary to the intent of Congress in EPCA."²⁶⁸²

Several commenters disagreed with the NPRM's suggestion that increases in U.S. oil production reduced the foreign policy implications relevant to the need of the U.S. to conserve energy. ACEEE commented that because the market for oil is global, "...regardless of actual imports, the nation is still affected by what happens to oil worldwide, and oil remains a foreign policy concern...."²⁶⁸³ Securing America's Energy Future commented that increased U.S. production "...has reduced some of the negative consequences of oil dependence, energy security is primarily a function of consumption, not production."²⁶⁸⁴ IPI argued that "...the agencies falsely and inconsistently argue that the need to conserve energy has diminished

²⁶⁸⁰ While the U.S. maintains a military presence in certain parts of the world to help secure global access to petroleum supplies, that is neither the primary nor the sole mission of U.S. forces overseas. Moreover, the scale of oil consumption reductions associated with CAFE standards would be insufficient to alter any existing military missions focused on ensuring the safe and expedient production and transportation of oil around the globe. Chapter 7 of the PRIA discussed this topic in more detail.

²⁶⁸¹ Securing America's Energy Future, NHTSA-2018-0067-12172, at 6.

²⁶⁸² CARB, NHTSA-2018-0067-11783, at 316.

²⁶⁸³ ACEEE, NHTSA-2018-0067-12122, main comments, at 2.

²⁶⁸⁴ Securing America's Energy Future, NHTSA-2018-0067-12172, at 6.

because U.S. reliance on foreign oil has decreased,” disagreeing with the NPRM’s assumption that monopsony and military security costs resulting from the proposal would be zero.²⁶⁸⁵ The States and Cities commenters raised similar points, stating that “U.S. military and foreign policy institutes” place emphasis on “global oil market stability and the stability of major oil-exporting nations,” which the States and Cities argued had not changed as U.S. exports have risen.²⁶⁸⁶ The States and Cities commenters further argued that if a quarter of U.S. oil consumed is still imported, then increases in consumption would necessarily raise imports, and thus also monopsony and military security costs associated with those imports.²⁶⁸⁷

CARB questioned whether it was accurate to assume that the U.S. would ever reach net exporter status, and commented that even if becoming a net exporter helped to insulate the Nation from the effects of reducing CAFE stringency, it would not lead to greater energy security until at least 2029, the first year for which AEO 2018 forecasts that the U.S. will stop being a net importer.²⁶⁸⁸ CARB further argued that increased domestic oil production did *not* insulate the U.S. from risk, and that in fact “...current conditions are more prone to risk due to lower available spare oil production capacity in major oil producing countries, meaning that a supply disruption is more likely to have a more pronounced effect on oil prices and U.S. energy security.”²⁶⁸⁹

Mr. Bordoff commented that geopolitical risk can still affect global oil prices, citing U.S. withdrawal from the Iran nuclear agreement and the reimposition of sanctions on Iranian oil sales; the collapse of Libyan oil production following conflict there; ongoing problems in Venezuela; a variety of short-term production outages in other producing areas; and even situations where geopolitics can result in lower prices rather than higher prices.²⁶⁹⁰

IPI stated that “...the *protective value* that the SPR offers given its size does automatically change as total U.S. petroleum consumption changes,” and argued that it was not sufficient to consider only “the budgetary costs for maintaining [the size of] the SPR.” IPI thus argued that “The agencies have failed to assess how much the relative protective value of the SPR will change as total U.S. consumption rises following the proposed rollback, and therefore have failed entirely to consider one important element of the national need to conserve energy.”²⁶⁹¹

Total energy independence for any country is only possible if it does not participate in the global energy markets, either because it consumes no energy (which is unrealistic) or because it

²⁶⁸⁵ IPI, NHTSA-2018-0067-12213, Appendix, at 2-3.

produces enough energy to meet all of its energy needs and uses only energy that is produced domestically. As discussed above, NHTSA agrees with commenters that the oil market is global, and that events and situations abroad can affect oil prices even as U.S. oil production increases. The fact that the U.S. became a net oil exporter, at least on a weekly basis, in November 2019, and the evidence indicates that it will become a net oil exporter on a longer-term basis in MY 2020 does not change geopolitics in many parts of the world. Striving for energy independence in a global market necessarily means *reducing* risks, because even if the U.S. consumed only domestically-produced petroleum and continued to export, the U.S. economy would still be subject to oil price fluctuations due to external events and situations. The NPRM was clear on all of these points.²⁶⁹² The NPRM and PRIA repeatedly emphasized that changes in the oil market meant that the risk of damage to the U.S. economy and of additional pain for U.S. drivers is *lower* than it was at the beginning of the CAFE program, not that it was eliminated entirely. NHTSA agrees with commenters that risk still exists, and that both production and consumption of oil are relevant to how big that risk might be. NHTSA simply believes, as explained in the NPRM and as explained again below, that the risk is lower than it would have been in the absence of the rapid growth in U.S. oil production, and that the lower risk means that the need of the U.S. to conserve energy, from this perspective, is less dire than it was at earlier points in the program.

The analyses for both the NPRM and the final rule account for the ongoing economic risk of participating in the global oil market by placing a value on energy security. The energy security value is made of several components. While commenters are correct that neither the NPRM nor the final rule analyses attributed a positive cost to the monopsony or military security components, the agencies do employ a cost for macroeconomic shock risk as part of energy security. Section VI discusses these estimates in more detail; for purposes of this discussion, NHTSA only notes that these issues are accounted for in the agencies' cost-benefit analysis, and to the extent that zero values are used for some elements, the reason for that is explained at length in those sections and public comments received on these issues did not present new information to change the agencies' minds on those values.

With regard to the comment that NHTSA should be accounting for the "protective value" of the SPR along with the literal cost of maintaining it, NHTSA is not in a position at this time to attempt to estimate such a value, and notes that the commenter provided no suggestions as to how to do so. The Department of Energy's website states that the maximum number of days of import protection provided by the SPR is 143 days, and that it takes 13 days from Presidential decision for SPR fuel to enter the market.²⁶⁹³ The 1973 OPEC oil embargo lasted from October 1973 to March 1974, roughly 150 days. As explained, NHTSA continues to believe that the effect of increased U.S. oil production is to stabilize, broadly, global oil markets. The longer a sustained spike in prices due to geopolitical events continues, the greater incentive U.S. shale

²⁶⁹² See 83 FR at 43213-15.

²⁶⁹³ See <https://www.energy.gov/fe/services/petroleum-reserves/strategic-petroleum-reserve/spr-quick-facts-and-faqs>.

production has to respond. NHTSA believes that it is foreseeable that the SPR could be utilized to help mitigate a price shock in the interim, for the majority of foreseeable shock situations.

(5) *Factors that NHTSA is prohibited from considering*

The NPRM explained that EPCA also provides that in determining the level at which it should set CAFE standards for a particular model year, NHTSA may not consider the ability of manufacturers to take advantage of several EPCA provisions that facilitate compliance with CAFE standards and thereby reduce the costs of compliance.²⁶⁹⁴ As discussed further in Section IX below, NHTSA cannot consider compliance credits that manufacturers earn by exceeding the CAFE standards and then use to achieve compliance in years in which their measured average fuel economy falls below the standards. NHTSA also cannot consider the use of alternative fuels by dual fuel vehicles nor the availability of dedicated alternative fuel vehicles—including battery-electric vehicles—in any model year. EPCA encourages the production of alternative fuel vehicles by specifying that their fuel economy is to be determined using a special calculation procedure that results in those vehicles being assigned a higher equivalent fuel economy level than they actually achieve.

The NPRM further explained that the effect of the prohibitions against considering these statutory flexibilities in setting the CAFE standards is that the flexibilities remain voluntarily-employed measures. If NHTSA were instead to assume manufacturer use of those flexibilities in setting new standards, higher standards would appear less costly and therefore more feasible, which would thus effectively require manufacturers to use those flexibilities in order to meet higher standards. By keeping NHTSA from including them in our stringency determination, the provision ensures that these statutory credits remain true compliance flexibilities.

Additionally, for the non-statutory fuel economy improvement value program that NHTSA developed by regulation, the NPRM stated that NHTSA does not consider these subject to the EPCA prohibition on considering flexibilities. EPCA is very clear as to which flexibilities are not to be considered. When the agency has introduced additional flexibilities such as A/C efficiency and “off-cycle” technology fuel economy improvement values, NHTSA has considered those technologies as available in the analysis. Thus, today’s analysis includes assumptions about manufacturers’ use of those technologies, as detailed in Section VI.

Michalek and Whitefoot commented that “[w]e find [the statutory prohibition on considering certain flexibilities in determining maximum feasible CAFE standards] problematic because the automakers use these flexibilities as a common means of complying with the regulation, and ignoring them will bias the cost-benefit analysis to overestimate costs.”²⁶⁹⁵ IPI

²⁶⁹⁴ 49 U.S.C. 32902(h).

²⁶⁹⁵ Michalek and Whitefoot, NHTSA-2018-0067-11903, at 10-11.

commented that “it is not clear that the statutory prohibition on considering credit availability was intended to apply to banked credits,” because 49 U.S.C. 32902(h)(3) was

added...as a ‘conforming amendment’ to EISA, which was the statute that gave NHTSA authority to allow credit trading and transferring; meanwhile, banking and borrowing have been part of NHTSA’s authority since EPCA in 1975. In 1989, e.g., NHTSA explicitly relied on the availability of ‘credit banks’ to justify maintaining the MY 1990 standard at 27.5 mpg instead of lowering its stringency. NHTSA has not explained why it now believes it may not more fully consider banking.²⁶⁹⁶

NHTSA agrees, as explained in the NPRM, that if the agency was able to consider the compliance flexibilities in determining maximum feasible standards, more-stringent standards would appear less costly and therefore more feasible. NHTSA is nevertheless bound by the statutory prohibition on considering the above-mentioned flexibilities. As for IPI’s disagreement that 32902(h)(3) should apply to banked credits because it was labeled a “conforming amendment,” NHTSA looks to the specific statutory language provided, which prohibits “[consideration], when prescribing a fuel economy standard, [of] the trading, transferring or availability of credits. . . .” (Emphasis added.) IPI’s suggested interpretation would render “availability” as surplusage. If Congress had meant the prohibition to apply only to traded and transferred credits, it would have said so. Instead, Congress also prohibited consideration of the “availability of credits,” which must be read reasonably to refer to “what credits are available,” i.e., banked credits. The fact that NHTSA considered the availability of banked credits in 1989, prior to establishment of this statutory prohibition, has no bearing in a post-EISA world.

Nonetheless, NHTSA notes that it is informed by the “real-world” analysis presented in the FRIA, which accounts for credit availability and usage, and manufacturers’ ability to employ alternative fueled vehicles—for purpose of conformance with E.O. 12866. Under the real-world analysis, compliance does, in fact, appear less costly. For example, today’s “real world” analysis shows manufacturers’ costs averaging about \$1,420 in MY 2029 under the final standards, as compared to the \$1,640 shown by the “standard setting” analysis. However, for purposes of determining maximum feasible CAFE levels, NHTSA considers only the “standard-setting” analysis shown in the NPRM, consistent with Congress’s direction.

f) EPCA/EISA requirements that no longer apply post-2020

The NPRM explained that Congress amended EPCA through EISA to add two requirements not yet discussed in this section relevant to determination of CAFE standards during the years between MY 2011 and MY 2020 but not beyond. First, Congress stated that, regardless of NHTSA’s determination of what levels of standards would be maximum feasible, standards must be set at levels high enough to ensure that the combined U.S. passenger car and

²⁶⁹⁶ IPI, NHTSA-2018-0067-12213, Appendix, at 19.

light truck fleet achieves an average fuel economy level of not less than 35 mpg no later than MY 2020.²⁶⁹⁷ And second, between MYs 2011 and 2020, the standards must “increase ratably” in each model year.²⁶⁹⁸ Neither of these requirements apply after MY 2020, so given that this rulemaking concerns the standards for MY 2021 and after, the NPRM stated that they are not relevant to this rulemaking.

CARB commented that because the proposal did not “provide for improved efficiency of motor vehicles” over the long term, “Stagnating the standards violates Congressional direction to ratably increase fuel economy when the technology for doing so has been demonstrated to exist (which it does...) or could be developed in the necessary time.”²⁶⁹⁹

NHTSA notes, again, that the statutory language is clear that Congress only directed ratable increases in stringency through MY 2020. After MY 2020, the statutory language is clear that standards simply need be “maximum feasible, as determined by the Secretary.” Some commenters may have disagreed that the proposal represented maximum feasible levels, but there is no statutory basis for arguing that the “ratable increase” requirement extends beyond MY 2020.

g) *Other considerations in determining maximum feasible standards*

The NPRM explained that NHTSA has historically considered the potential for adverse safety consequences in setting CAFE standards. This practice has been consistently approved in case law. As courts have recognized, “NHTSA has always examined the safety consequences of the CAFE standards in its overall consideration of relevant factors since its earliest rulemaking under the CAFE program.” *Competitive Enterprise Institute v. NHTSA*, 901 F.2d 107, 120 n. 11 (D.C. Cir. 1990) (“*CEI-I*”) (citing 42 Fed. Reg. 33534, 33551 (June 30, 1977)). The courts have consistently upheld NHTSA’s implementation of EPCA in this manner. *See, e.g., Competitive Enterprise Institute v. NHTSA*, 956 F.2d 321, 322 (D.C. Cir. 1992) (“*CEI-II*”) (in determining the maximum feasible fuel economy standard, “NHTSA has always taken passenger safety into account”) (citing *CEI-I*, 901 F.2d at 120 n. 11); *Competitive Enterprise Institute v. NHTSA*, 45 F.3d 481, 482-83 (D.C. Cir. 1995) (“*CEI-III*”) (same); *Center for Biological Diversity v. NHTSA*, 538 F.3d 1172, 1203-04 (9th Cir. 2008) (upholding NHTSA’s analysis of vehicle safety issues associated with weight in connection with the MYs 2008-2011 light truck CAFE rulemaking). Thus, NHTSA explained that in evaluating what levels of stringency would result in maximum feasible standards, NHTSA assesses the potential safety impacts and considers them in balancing the statutory considerations and to determine the maximum feasible level of the standards.

The attribute-based standards that Congress requires NHTSA to set help to mitigate the negative safety effects of the historical single number standards originally required in EPCA, and in past rulemakings, NHTSA constrained its modeling so as not to consider possible mass

²⁶⁹⁷ 49 U.S.C. 32902(b)(2)(A).

²⁶⁹⁸ 49 U.S.C. 32902(b)(2)(C).

²⁶⁹⁹ CARB, NHTSA-2018-0067-11873, Detailed Comments, at 84.

reduction in lower weight vehicles in its analysis, which affected the resulting assessment of potential adverse safety impacts. That analytical approach did not reflect, however, the likelihood that automakers may pursue the most cost-effective means of improving fuel efficiency to comply with CAFE requirements. For the NPRM, as for the final rule, the modeling did not limit the amount of mass reduction that is applied to any segment, but rather considered that automakers may apply mass reduction based upon cost-effectiveness, similar to most other technologies. NHTSA does not, of course, mandate the use of any particular technology by manufacturers in meeting the standards. The NPRM and today's final rule, like the Draft TAR, also considered the safety effect associated with the additional vehicle miles traveled due to the rebound effect.

NHTSA explained that the NPRM considered the safety effects of vehicle scrappage rates on the fleet as a whole. The NPRM also explained NHTSA's consideration of the effect of additional expenses in fuel savings technology on the affordability of vehicles—the likelihood that increased standards will result in consumers being priced out of the new vehicle market and choosing to keep their existing vehicle or purchase a used vehicle. Since new vehicles are significantly safer than used vehicles, slowing fleet turnover to newer vehicles results in older and less safe vehicles remaining on the roads longer. NHTSA stated that this significantly affects the safety of the United States light duty fleet, as described more fully in the safety section of the NPRM and in Chapter 11 of the PRIA. Furthermore, as fuel economy standards become more stringent, and more fuel efficient vehicles are introduced into the fleet, fueling costs are reduced. This results in consumers driving more miles, which results in more crashes and increased highway fatalities.

A number of commenters disagreed with a variety of aspects of the NPRM's analysis of safety, and several also disagreed with how NHTSA considered safety along with the other factors in the proposal. The States and Cities commenters, for example, agreed that "NHTSA has historically considered safety impacts when setting maximum feasible standards," but argued that:

in the Proposed Rollback, NHTSA departs from its past practice by relying on completely novel and unsupported theories regarding the linkages between fuel economy and safety that do not reflect reality. In the past, NHTSA has considered the safety of the technologies that improve fuel economy. [citations omitted] In the Proposed Rollback, however, NHTSA has linked safety concerns with rebound and scrappage effects of more stringent fuel economy standards. [citations omitted] As discussed [elsewhere], these theories are unsupported, implausible, and contradicted by numerous experts—rendering them arbitrary and capricious. The agency has also failed to acknowledge or adequately justify its break with past analyses of safety. *See Fox Television*, 556 U.S. at 515.”²⁷⁰⁰

²⁷⁰⁰ States and Cities, NHTSA-2018-0067-11735, at 77.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

EDF commented that NHTSA cannot “...lawfully rely upon the repercussions of increased driving as a justification.... The fact that the standards do not ‘compel’ this driving prevents such reliance, and...[EPCA/EISA] nowhere indicate that [NHTSA] can refuse to comply with [its] statutory obligations by pointing to a projection that individuals might drive more and in doing so, some of them will get into traffic accidents.”²⁷⁰¹ EDF further argued that:

It is especially unlikely that Congress intended for NHTSA to consider potential increases in driving (or... ‘VMT’). Under basic economic theory and under the Agency’s traditional analysis (including their analysis of this proposal), an improvement in fuel economy—which makes driving cheaper—would be expected to lead to some increase in driving for households that are sensitive to and conscious of that effect on their budgets. Thus, consideration of VMT impacts could be used to undermine *any* fuel economy standard. Because VMT is ‘a factor [that] is both so indirectly related to [fuel economy] and so full of potential for canceling the conclusions drawn from [a fuel economy analysis] . . . it would surely have been expressly mentioned in [the statute] had Congress meant it to be considered.’ *Whitman v. Am. Trucking Associations*, 531 U.S. 457, 469 (2001).”²⁷⁰²

Other comments on safety as part of the legal justification varied. NESCAUM claimed that NHTSA’s safety justification “is disputed by EPA’s technical staff based on their identification of flaws in NHTSA’s analysis,” suggesting that it was therefore invalid and not a basis for decision-making.²⁷⁰³ Global commented that there was no policy reason for freezing the level of standards due to mass reduction concerns (i.e., safety), given footprint standards.²⁷⁰⁴ IPI argued that it was inappropriate to account for vehicle safety-related deaths and injuries “without an adequate discussion of the health and safety impacts of the Proposed Rule’s increased emissions or without an accurate estimate of the actual safety impact of the rollback versus the 2012 standards.”²⁷⁰⁵

NHTSA agrees with commenters that the safety analysis conducted to inform this rulemaking (both NPRM and final rule) is different from—broader than—past safety analyses conducted to inform CAFE and CO₂ rulemakings. NHTSA disagrees, however, that the agency failed to acknowledge or explain this fact. The NPRM directly acknowledges and explains the evolution of the safety analysis over time and why, specifically, the NPRM included the safety effects of rebound and scrappage phenomena.²⁷⁰⁶ The NPRM also expressly sought comment on these elements of the safety analysis and the safety analysis generally, before explaining how

²⁷⁰⁶ See 83 FR at 43106-07.

they worked and describing their tentative findings in considerable detail. It is inaccurate for commenters to claim that the agency did not acknowledge or explain these changes. Commenters' disagreement with the substance of the safety analysis does not create a valid process complaint here. Section VI discusses in detail the comments received on the substance of the safety analysis, including a number of comments citing deliberative feedback provided by some members of EPA staff during NPRM development, and contains the agencies' responses. With regard to the comment from EDF, as explained above, the premise that vehicles may be driven more or less in response to more or less stringent CAFE (or CO₂) standards is called the rebound effect, and it is discussed at length in Section VI above. The rebound effect has been factored into rulemaking cost-benefit analyses and reduced CAFE and CO₂ standard benefits in such analyses for well over a decade,²⁷⁰⁷ and EPA and NHTSA have written repeatedly about and considered the magnitude of this effect. NHTSA is aware that some commenters disagree that a rebound effect even exists for fuel economy, and understands how such commenters would correspondingly disagree that VMT-related safety effects could arise from differences in CAFE standards. But NHTSA does not agree that the rebound effect is zero, and correspondingly believes that safety effects from additional driving (due to exposure to crashes) exist and are capable of quantification for analytical purposes.

Moreover, if EDF were correct that agencies may consider only the behavior that regulations directly "compel," then CAFE analysis would be challenged to consider even fuel savings—the purpose of CAFE standards—because the standards do not compel Americans to drive, or to buy new vehicles, or to buy any vehicles at all. Reasonable assumptions about how much Americans drive (depending on how much it costs to drive, among other things), and what vehicles Americans buy and how often they buy them (depending on how much those vehicles cost, among other things), are useful and important for including in analyses that help decision-makers distinguish between different levels of potential CAFE standards. Circular A-4 additionally directs agencies to consider ancillary effects of rulemakings.²⁷⁰⁸ NHTSA believes that it is reasonable to consider these effects as part of the safety analysis, and to consider safety effects as part of its determination of maximum feasible standards.

²⁷⁰⁷ See, e.g., 68 FR 16868, 16878 (Apr. 7, 2003).

²⁷⁰⁸ See OIRA, "Regulatory Impact Analysis: A Primer," at 7, https://www.reginfo.gov/public/jsp/Utilities/circular-a-4_regulatory-impact-analysis-a-primer.pdf ("In addition to the direct benefits and costs of each alternative, the list should include any important ancillary benefits and countervailing risks. An ancillary benefit is a favorable impact of the alternative under consideration that is typically unrelated or secondary to the purpose of the action (e.g., reduced refinery emissions due to more stringent fuel economy standards for light trucks). A countervailing risk is an adverse economic, health, safety, or environmental consequence that results from a regulatory action and is not already accounted for in the direct cost of the action (e.g., adverse safety impacts from more stringent fuel-economy standards for light trucks). As with other benefits and costs, an effort should be made to quantify and monetize both ancillary benefits and countervailing risks.")

2. Administrative Procedure Act

To be upheld under the “arbitrary and capricious” standard of judicial review in the APA, an agency rule must be rational, based on consideration of the relevant factors, and within the scope of the authority delegated to the agency by the statute. The agency must examine the relevant data and articulate a satisfactory explanation for its action including a “rational connection between the facts found and the choice made.”²⁷⁰⁹

Statutory interpretations included in an agency’s rule are subject to the two-step analysis of *Chevron, U.S.A. v. Natural Resources Defense Council*.²⁷¹⁰ Under step one, where a statute “has directly spoken to the precise question at issue,” *id.* at 842, the court and the agency “must give effect to the unambiguously expressed intent of Congress.”²⁷¹¹ If the statute is silent or ambiguous regarding the specific question, the court proceeds to step two and asks “whether the agency’s answer is based on a permissible construction of the statute.”²⁷¹²

If an agency’s interpretation differs from the one that it has previously adopted, the agency need not demonstrate that the prior position was wrong or even less desirable. Rather, the agency would need only to demonstrate that its *new* position is consistent with the statute and supported by the record and acknowledge that this is a departure from past positions. The Supreme Court emphasized this in *FCC v. Fox Television*.²⁷¹³ When an agency changes course from earlier regulations, “the requirement that an agency provide a reasoned explanation for its action would ordinarily demand that it display awareness that it *is* changing position,” but “need not demonstrate to a court’s satisfaction that the reasons for the new policy are *better* than the reasons for the old one; it suffices that the new policy is permissible under the statute, that there are good reasons for it, and that the agency *believes* it to be better, which the conscious change of course adequately indicates.”²⁷¹⁴ The APA also requires that agencies provide notice and comment to the public when proposing regulations,²⁷¹⁵ as we did when publishing the NPRM for this rulemaking.

a) Requests to extend the comment period

On August 2, 2018, the agencies published the NPRM on the agencies’ respective websites, soliciting public comments.²⁷¹⁶ On August 24, 2018, the *Federal Register* published

²⁷⁰⁹ *Burlington Truck Lines, Inc., v. United States*, 371 U.S. 156, 168 (1962).

²⁷¹⁰ 467 U.S. 837 (1984).

²⁷¹¹ *Id.* at 843.

²⁷¹² *Id.*

²⁷¹³ 556 U.S. 502 (2009).

²⁷¹⁴ *Id.*, at 1181.

²⁷¹⁵ 5 U.S.C. 553.

²⁷¹⁶ <https://www.nhtsa.gov/corporate-average-fuel-economy/safe>; <https://www.epa.gov/newsreleases/us-epa-and-dot-propose-fuel-economy-standards-my-2021-2026-vehicles>.

the NPRM, which began a 60-day public comment period.²⁷¹⁷ The public comment period would have ended on October 23, 2018, but the agencies extended the comment period until October 26, 2018.²⁷¹⁸ In the *Federal Register* notice extending the comment period, the agencies explained that they were denying requests for an extension of the comment period by at least 60 days, explaining that “[a]utomakers will need maximum lead time to respond to the final rule[.]”²⁷¹⁹ Although the comment period ultimately closed on October 26, 2018, the agencies’ dockets remained open, and the agencies continued to accept and consider comments, to the extent possible, for more than one year after the comment period began.²⁷²⁰

After publishing the NPRM, the agencies received a number of requests to extend the comment period, generally for an additional 60 days.²⁷²¹ For example, seventeen States and the District of Columbia jointly requested a 60-day extension of the comment period.²⁷²² That request cited the voluminous record, the complexity of the material, and the profound potential impact on human health and the environment, among other things.²⁷²³ The City of Los Angeles and New York State Department of Environmental Conservation also requested a 60-day extension, for similar reasons.²⁷²⁴ In addition, 32 United States Senators jointly requested a 60-day extension of the comment period.²⁷²⁵ The Senators argued that an extension was appropriate to ensure adequate public participation with such an important rule.²⁷²⁶ Several non-government organizations similarly requested a 60-day extension of the comment period due to the complexity of the issues and the importance of the proposed rule.²⁷²⁷ Other organizations also requested a 60-day extension, stressing the complexity of the issues and the significance of the proposed rule’s impact on the environment.²⁷²⁸ The American Lung Association also requested a

²⁷¹⁷ 83 FR 42986 (Aug. 24, 2018).

²⁷¹⁸ See 83 FR 48578 (Sept. 26, 2018) (extending comment period).

²⁷¹⁹ *Id.*

²⁷²⁰ The agencies notified the public of this possibility in the NPRM, stating that: “To the extent practicable, we will also consider comments received after” the close of the comment period. 83 FR 42986, 43471 (Aug. 24, 2018).

²⁷²¹ See 83 FR 48578 (Sept. 26, 2018).

²⁷²² See comments from the State of California et al., Request for an extension, Docket No. NHTSA-2018-0067-3458.

²⁷²³ See *id.*

²⁷²⁴ Also for similar reasons, the Minnesota Pollution Control Agency and the Minnesota Department of Transportation submitted a joint request for a 120-day extension of the comment period. See comments from the Minnesota Pollution Control Agency and Minnesota Department of Transportation, Docket No. NHTSA-2018-0067-3580.

²⁷²⁵ See comments from 32 U.S. Senators (Kamala D. Harris et al.), Docket No. NHTSA-2018-0067-5643.

²⁷²⁶ See *id.*

²⁷²⁷ See, e.g., comments from the Alliance of Automobile Manufacturers, Docket No. NHTSA-2018-0067-3619; Communities for a Better Environment, Docket No. EPA-HQ-OAR-2018-0283-1095; Consumer Federation of America, NHTSA-2018-0067-3400; Edison Electric Institute, received by mail; and South Coast Air Quality Management District, Docket No. EPA-HQ-OAR-2018-0283-0885.

²⁷²⁸ See, e.g., comments from the Environmental Law and Policy Center, NHTSA-2018-0067-2728; Georgetown Climate Center, Docket No. NHTSA-2018-0067-3610; Center for Biological Diversity, Conservation Law Foundation, Earthjustice, Environmental Defense Fund, Natural Resources Defense Council, Public Citizen,

60-day extension of the comment period, asserting that it needed more time to analyze the impact of the proposed rule on human health.²⁷²⁹ The California Air Resources Board (CARB) likewise requested a 60-day extension, in part, based on information that it asserted should have been included in the NPRM.²⁷³⁰ New York University School of Law’s Institute for Policy Integrity similarly requested a 60-day extension based on information that it contended should have been included in the NPRM’s “sensitivity analysis table for the ‘Cumulative Changes in Fleet Size, Travel (VMT), Fatalities, Fuel Consumption and CO₂ Emissions through MY2029.’”²⁷³¹

The agencies do not believe a further extension of the comment period was warranted under the circumstances.²⁷³² The APA does not specify a minimum number of days for a comment period.²⁷³³ Two Executive Orders also provide direction to Federal agencies with respect to the length of a comment period for a proposed rule.²⁷³⁴ Executive Order 12,866 states that “[e]ach agency shall (consistent with its own rules, regulations, or procedures) provide the public with meaningful participation in the regulatory process In addition, each agency should afford the public a meaningful opportunity to comment on any proposed regulation, which in most cases should include a comment period of not less than 60 days.”²⁷³⁵ Additionally, Executive Order 13,563 reaffirmed Executive Order 12,866’s directive that comment periods should generally not be less than 60 days, stating: “To the extent feasible and permitted by law, each agency shall afford the public a meaningful opportunity to comment through the Internet on any proposed regulation, with a comment period that should generally be at least 60 days.”²⁷³⁶ More recently, in December of 2018, the Department of Transportation implemented DOT Order 2100.6, which provides its operating administrations, including NHTSA, with direction on appropriate rulemaking processes and procedures.²⁷³⁷ While not yet effective at the time the proposal was published, the Order provides that “the comment period for significant DOT rules should be at least 45 days.”²⁷³⁸ The 63 day comment period for the proposal far exceeded this amount.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Consistent with these principles, courts give broad discretion to agencies in determining the reasonableness of a comment period. Courts have frequently upheld comment periods that were significantly less than the 63-day comment period here. *See Connecticut Light & Power Co. v. Nuclear Regulatory Comm'n*, 673 F.2d 525, 534 (D.C. Cir. 1982) (upholding a 30-day comment period and stating that “neither statute nor regulation mandates that the agency do more”); *see also North American Van Lines v. ICC*, 666 F.2d 1087, 1092 (7th Cir. 1981) (upholding a 45-day comment period).²⁷³⁹ In addition to the length of a comment period, courts consider the number of comments received and whether comments had an effect on an agency’s final rule, in assessing whether the public had a meaningful opportunity to comment.²⁷⁴⁰

These principles are easily satisfied here. Here, the agencies initially provided a 60-day comment period and then further extended it to ensure compliance with the Clean Air Act. The Clean Air Act requires that the record of proceedings allowing oral presentation of data, views, and arguments on a proposed rule be kept open for 30 days after completion of a proceeding to provide an opportunity for submission of rebuttal and supplementary information.²⁷⁴¹ Because the final “proceeding allowing oral presentation of data, views, and arguments” was expected to be on September 26, 2018, the comment period for the proposed rule was extended by three days to meet that requirement.²⁷⁴²

The 63-day comment period was consistent with what the law requires.²⁷⁴³ While the agencies understand and agree with commenters about the importance and complexity of the issues here, the public docket demonstrates that the public had a meaningful opportunity to comment on the proposed rule.²⁷⁴⁴ The agencies received a total of more than 750,000 public comments, many of which commented on detailed, technical portions of the proposed rule. For instance, the California Air Resources Board provided 415 pages of detailed comments involving very specific aspects of the proposal,²⁷⁴⁵ and the Auto Alliance filed 202 pages of detailed comments, and commissioned a separate econometric study analyzing the effects of multiple alternatives.²⁷⁴⁶ This is clear evidence that the public had not only the opportunity to review and comment on the proposal, but to do so with an extraordinary level of detail.

²⁷³⁹ In certain circumstances, particularly urgent ones, courts have even upheld comment periods of less than 30 days. *See Omnipoint Corp. v. FCC*, 78 F.3d 620, 629–30 (D.C. Cir. 1996) (holding that a 14-day comment period was sufficient given the “urgent necessity for rapid administrative action under the circumstances”); *see also Fla. Power & Light Co. v. United States*, 846 F.2d 765, 772 (D.C. Cir. 1988) (upholding a 15-day comment period given a deadline that Congress imposed on the Nuclear Regulatory Commission to finalize its rule).

²⁷⁴⁰ *See Florida Power & Light, Co. v. United States*, 846 F.2d 765, 772 (D.C. Cir. 1988); *see also Conference of State Bank Sup’rs v. Office of Thrift Supervision*, 792 F. Supp. 837, 844 (D.D.C. 1992).

²⁷⁴¹ 42 U.S.C. 7607(d)(5).

²⁷⁴² *See* 83 FR 48578, 48581 (Sept. 26, 2018).

²⁷⁴³ In any event, the two Executive Orders explicitly state that they do not create any enforceable right or benefit by a party against any federal agency. *See* Executive Order 12,866 § 10; *see also* Executive Order 13,563 § 7(d).

²⁷⁴⁴ *See Rural Cellular Ass’n v. FCC*, 588 F.3d 1095, 1101 (D.C. Cir. 2009).

²⁷⁴⁵ NHTSA-2018-0067-11873.

²⁷⁴⁶ NHTSA-2018-0067-12073.

Finally, notwithstanding the sufficiency of the agencies' 63-day comment period, the agencies published their NPRM on their websites on August 2, 2018, more than three weeks before the comment period formally opened on August 24, and this effectively provided the public with 22 additional days in which to review the proposal and draft comments. The agencies' public dockets also remained open for more than one year after the start of the comment period, and the agencies considered late comments received, to the extent practicable.

b) Other comments on public participation

Several commenters objected to NHTSA's 15-page limit on primary comments, asserting that it impacted the public's ability to meaningfully participate in the rulemaking process.²⁷⁴⁷ However, as certain of the commenters acknowledged, the NPRM also explicitly stated that commenters could also submit attachments—without any page limit.²⁷⁴⁸ Thus, the page limit on primary comments did not prevent commenters from presenting any information they deemed relevant to the agencies. Both primary comments and their attachments are available in the agencies' public dockets, and were considered by the agencies in this rulemaking as demonstrated by the responses to comments discussed throughout this final rule.

NHTSA's 15-page limit simply prescribed the form that comments should take: a concise summary comment of up to 15 pages, with optional attachments with no page limit. Many commenters submitted extensive attachments to their comments, including commenters that objected to the 15-page limit for primary comments. For example, several States and cities that jointly commented submitted a 13-page primary comment, accompanied by 145 pages of "detailed comments" and three appendices totaling 101 additional pages.²⁷⁴⁹ The 15-page limit had the effect of creating executive summaries of otherwise voluminous comments, which increased efficiency during the rulemaking process. This was NHTSA's stated purpose for the 15-page limit. As explained in the NPRM: "NHTSA established this limit to encourage you to write your primary comments in a concise fashion."²⁷⁵⁰ In any event, no commenter was prevented from submitting information to the agencies based on NHTSA's page limitation for primary comments. The agencies strongly disagree that public participation was impeded by NHTSA's specification that primary comments were limited to 15 pages.

²⁷⁴⁷ See States of California et al., Attachment1_States and Cities Detailed Comments, Docket No. NHTSA-2018-0067-11735, at 46; Center for Biological Diversity, et al., NHTSA-2018-0067-12088; CARB, NHTSA-2018-0067-1187; Environmental Defense Fund, NHTSA-2018-0067-12108; BlueGreen Alliance, NHTSA-2018-0067-12440; Connecticut Department of Energy and Environmental Protection (DEEP), EPA-HQ-OAR-2018-0283-4202.

²⁷⁴⁸ 83 FR 43470 (Aug. 24, 2018) (citing 49 CFR 553.21).

²⁷⁴⁹ States of California et al., NHTSA-2018-0067-11735.

²⁷⁵⁰ 83 FR 43470 (Aug. 24, 2018).

On August 2, 2018, the agencies published a joint Notice of Proposed Rulemaking (NPRM) on the agencies' respective websites, which solicited public comments on "The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks."²⁷⁵¹ The NPRM indicated that the public may submit written comments by any of the following methods: online through the Federal eRulemaking Portal at www.regulations.gov, by fax, by mail, or by hand delivery. The NPRM also notified the public that the agencies planned to hold three joint public hearings, and would accept oral and written comments at the hearings. The NPRM indicated that the agencies planned to hold the hearings in Washington, D.C.; the Detroit, Michigan area; and the Los Angeles, California area, but indicated that the specific addresses and dates for the hearings would be announced in a supplemental *Federal Register* notice.²⁷⁵² On August 24, 2018, the agencies published a notice in the *Federal Register*, which provided new locations for two of the three hearings and added dates for each hearing.²⁷⁵³ That notice informed the public that the agencies planned to hold three joint public hearings during the comment period: 1) on September 24, 2018 in Fresno, California; 2) on September 25, 2018 in Dearborn, Michigan; and 3) on September 26, 2018 in Pittsburgh, Pennsylvania.²⁷⁵⁴

The agencies also received several comments with respect to the sufficiency of the agencies' public hearings during the comment period. For example, the South Coast Air Quality Management District asserted that EPA failed to meet its obligation to hold public hearings under the Clean Air Act, claiming that an EPA "political appointee" did not have the legal authority to change hearing locations.²⁷⁵⁵ The comment also claimed that holding certain of the hearings in smaller metropolitan areas than originally announced resulted in 15 million fewer potential participants in the hearings.²⁷⁵⁶ Additionally, the comment noted that the NPRM and the notice that set the new locations of two of the public hearings were both published in the *Federal Register* on the same day, yet those documents contained conflicting hearing locations (the NPRM listed the originally planned hearing locations).²⁷⁵⁷

Similarly, seventeen States and the District of Columbia submitted a joint comment requesting that the agencies reinstate the hearing locations that were initially listed in the NPRM, with the stated goal of maximizing the number of public participants.²⁷⁵⁸ Similarly, a group of

²⁷⁵¹ <https://www.nhtsa.gov/corporate-average-fuel-economy/safe>; <https://www.epa.gov/newsreleases/us-epa-and-dot-propose-fuel-economy-standards-my-2021-2026-vehicles>. The Agencies subsequently published the NPRM in the *Federal Register* on August 24, 2018. 83 FR 42986 (August 24, 2018).

²⁷⁵² 83 FR 42986 (August 24, 2018).

²⁷⁵⁸ See comments from the State of California et al., Request for an extension, Docket No. NHTSA-2018-0067-3458.

environmental organizations jointly submitted a comment stating that the new hearing locations failed to maximize the potential participants for the agencies' public hearings.²⁷⁵⁹ That group also asserted that the agencies failed to provide a reason for the agencies' denial of requests to hold more than three public hearings.²⁷⁶⁰

The agencies more than satisfied their legal obligation with respect to holding public hearings, and the three hearings provided substantial additional opportunity for public participation. While the agencies understand that some commenters were disappointed with some aspects of the process, those commenters did not demonstrate that the agencies' process was legally deficient, nor that any party suffered prejudice from the changes the agencies made to their public hearing arrangement.

The APA does not require agencies to hold public hearings during the rulemaking process, unless the opportunity for a public hearing is required by a governing statute.²⁷⁶¹ NHTSA's governing fuel economy statute does not require a public hearing during the rulemaking process.²⁷⁶² The Clean Air Act requires EPA to "give interested persons an opportunity for the oral presentation of data, views, or arguments, in addition to an opportunity to make written submissions" 42 U.S.C. 7607(d)(5)(ii). The agencies' three joint public hearings satisfied this statutory requirement.

The agencies note that it was clear from the NPRM that the hearings were not yet finalized. No addresses or dates were announced for the hearings, and the NPRM indicated that information on the hearings would be forthcoming in a supplemental *Federal Register* notice. The NPRM (signed by the EPA Administrator) indicated that three hearings would be held, and the fact that specific details about those hearings were announced in a later notice signed by a different political appointee does not itself make the hearings themselves invalid. The Clean Air Act does not mandate hearings in any particular location and the public was aware from the NPRM that additional information on the hearings would be forthcoming. To the extent that any

²⁷⁵⁹ See comments from the Center for Biological Diversity, Conservation Law Foundation, Environmental Defense Fund, Earthjustice, Environmental Law and Policy Center, Natural Resources Defense Council, Public Citizen, Inc., Sierra Club, and Union of Concerned Scientists, Appendix A - Coalition Comment Letter (10-26-2018), Docket No. NHTSA-2018-0067-12000, at 213. A number of other commenters also requested that the Agencies hold additional public hearings. See, e.g., comments from the Georgetown Climate Center, 20180906 - GCC Comments to NHTSA and EPA, Docket No. NHTSA-2018-0067-3610; The City of Los Angeles, Docket No. NHTSA-2018-0067-4159, at 2-3; California Air Resources Board, 2018-09-11 SAFE Rule DEIS – CARB Req Add Info, Docket No. NHTSA-2018-0067-4166, at 1; Northeast States for Coordinated Air Use Management, NESCAUM SAFE rule request for comment extension and hearing_20180824, Docket No. NHTSA-2018-0067-2158, at 1-2.

²⁷⁶⁰ *Id.*

²⁷⁶¹ See 5 U.S.C. 553(c). Absent a statutory requirement, the APA gives agencies the discretion whether or not to hold a public hearing, stating that "the agency shall give interested persons an opportunity to participate in the rule making through submission of written data, views, or arguments with or without opportunity for oral presentation." *Id.*

²⁷⁶² See 49 U.S.C. 32902.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

individual person or group was inconvenienced by the change in location announced in the supplemental notice, they still had ample time to submit public comments through any of the multiple other available methods indicated in the NPRM.²⁷⁶³

The agencies regret any confusion that resulted from publication of the NPRM in the *Federal Register* on the same date as publication of the notice that updated the hearing locations and provided additional information, including hearing dates. However, because the NPRM did not include dates for the hearings, and the NPRM informed interested parties to look for an additional notice that would announce specific dates and addresses for the hearings, no one could have relied on the NPRM to the exclusion of the supplemental notice.²⁷⁶⁴

The agencies ultimately held three public hearings, as was originally announced. There is no Clean Air Act requirement for a particular number of hearings, and by holding the hearings in locations throughout the United States (including in California), the agencies offered a meaningful opportunity for participation. Moreover, the public docket remained open for two months subsequent to the announcement of the final hearing locations, providing any interested party who was unable to attend a public hearing ample opportunity to submit comments in writing. As evidence of this meaningful opportunity to comment on the proposed rule, the agencies received a total of more than 750,000 public comments.

Several commenters also asserted that the agencies delayed posting the hearing transcripts to the public docket until October 25, which was one day before the close of the public comment period.²⁷⁶⁵ The Environmental Defense Fund claimed that this was inconsistent with the Clean Air Act's requirements that "[t]he transcript of public hearings, if any, on the proposed rule shall also be included in the docket promptly upon receipt from the person who transcribed such hearings." 42 U.S.C. 7607(d)(4)(B).²⁷⁶⁶ As one commenter acknowledged, the transcripts were certified by the reporters on September 26, 2018 (Pittsburgh hearing), September 27, 2018 (Dearborn hearing), and October 1, 2018 (Fresno hearing).²⁷⁶⁷ The agencies made the transcripts publicly available within a reasonable period. Moreover, it was reasonable for the agencies to have an opportunity to review the transcripts for errors prior to making them publicly available. While the concern expressed by these commenters was an inadequate ability to offer responsive comments to the transcripts, the rulemaking process would be never-ending if every commenter had an opportunity to respond to every other commenter. There is no such

²⁷⁶³ Executive Order 13,563 offers guidance to agencies with respect to how to maximize public participation. The Executive Order states that agencies should "afford the public a meaningful opportunity to comment through the Internet on any proposed regulation" The vast majority of the comments the agencies received in this rulemaking were submitted through the internet.

²⁷⁶⁴ Additionally, as a matter of fairness, the agencies gave interested parties notice about the change in public hearing locations one month prior to the first public hearing. See 83 FR 42817 (August 24, 2018).

²⁷⁶⁵ Environmental Defense Fund, NHTSA-2018-0067-12108, NHTSA-2018-0067-12327, NHTSA-2018-0067-12371; State of California et al., NHTSA-2018-0067-11735.

²⁷⁶⁷ State of California et al., NHTSA-2018-0067-11735.

requirement in the APA, the Clean Air Act, or otherwise. The public had sufficient opportunity to comment on the agencies' proposals, as described above.

A few commenters requested that the agencies host a workshop or webinar to help commenters better understand the agencies' modeling and analyses.²⁷⁶⁸ The commenters pointed to similar activities undertaken by EPA for other complex rulemakings. While the agencies did not conduct a live workshop or webinar regarding the proposal, they did make extensive information publicly available beyond the contents of the NPRM. To assist the public, NHTSA hosted a dedicated webpage with information on the modeling.²⁷⁶⁹ The webpage included a video introduction to the CAFE model.²⁷⁷⁰ The webpage enabled members of the public to download the model software, its system documentation, source code, and input files.²⁷⁷¹ Many commenters commented in detail on the modeling and analyses. However, the agencies recognize that public stakeholders vary in their experience and understanding of the modeling and analyses and will continue to consider ways to facilitate public participation in future rulemakings, which could include the use of workshops or webinars.

Some comments criticized the agencies for the agencies' untimeliness in adding materials to the rulemaking dockets, for example, identifying material "that was not added to the rulemaking docket until the end of the original comment period or, in some cases, added either after that period already had closed or not at all."²⁷⁷²

The critical question is "whether the final rule changes critically from the proposed rule rather than on whether the agency relies on supporting material not published for comment."²⁷⁷³ In other words, "[t]he question is typically whether the agency's final rule so departs from its proposed rule as to constitute more surprise than notice."²⁷⁷⁴ To that end, agencies are allowed—as the agencies here did—to rely on supplemental data that clarified, expanded on, or confirmed information in the proposed rule, even if that supplemental data was not disclosed in the proposed rule.²⁷⁷⁵ In any event, the commenters have failed to show how they were prejudiced by any information posted later than they would have preferred.²⁷⁷⁶

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Some commenters noted that certain aspects of the CAFE model used for the proposal were not previously subject to peer review.²⁷⁷⁷ Certain commenters asserted that the proposal was legally flawed because the full CAFE model was not peer reviewed prior to the proposal.²⁷⁷⁸ In support of this argument, commenters cited the Information Quality Act and related OMB guidance that states that “each agency shall have a peer review conducted on all influential scientific information that the agency intends to disseminate.”²⁷⁷⁹ Commenters also cited EPA’s Peer Review Handbook, which states: “For highly influential scientific assessments, external peer review is the expected procedure.”²⁷⁸⁰

The agencies agree that peer review is appropriate for the CAFE model, and the CAFE model has been peer reviewed. As discussed in the NPRM, and as certain commenters acknowledged, the CAFE model was peer reviewed in 2017.²⁷⁸¹ NHTSA included peer review materials in the public docket as well as on its webpage regarding the model.²⁷⁸² As described in those materials: “In 2017, the Volpe Center arranged for a formal peer review of the version of the CAFE model released and documented in 2016 All of the peer reviewers supported much about the model’s general approach, and supported many of the model’s specific characteristics. Peer reviewers also provided a variety of general and specific recommendations regarding potential changes to the model, inputs, outputs, and documentation. NHTSA and Volpe Center staff agree with many of these recommendations and have either completed or begun work to implement many of them; implementing others would require further research, testing, and development not possible at this time, but we are considering them for future model versions.”²⁷⁸³

However, certain new elements of the CAFE model were not completed at the time of the 2017 peer review.²⁷⁸⁴ NHTSA subsequently obtained a peer review of significant new elements added to the model after the 2017 peer review.²⁷⁸⁵ As described in the new peer review charge, included in a July 2019 report included in the rulemaking docket, NHTSA explained:

²⁷⁷⁷ See, e.g., Center for Biological Diversity et al., NHTSA-2018-0067-12000; Environmental Defense Fund, NHTSA-2018-0067-12327; Environmental Defense Fund et al., NHTSA-2018-0067-12371; Environmental Defense Fund et al., NHTSA-2018-0067-12406; Center for Biological Diversity, Environment America, Environmental Defense Fund, Environmental Law Policy Center, Public Citizen, Inc., Sierra Club, and Union of Concerned Scientists, NHTSA-2018-0067-12439; States of California et al., NHTSA-2018-0067-11735.

²⁷⁸⁵ NHTSA-2018-0067-0055.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

To inform the proposed rule announced in August 2018, DOT staff introduced significant new elements to the model, including methods to estimate changes in vehicle sales volumes, vehicle scrappage, and automotive sector labor usage. Each of these regulatory actions involved consideration of and response to significant public comment on model results, as well as comments on the model itself. In addition to DOT staff's own observations, these comments led DOT staff to make a wide range of improvements to the model. Insofar as a formal peer review could identify additional potential opportunities to improve the model, DOT sponsored a review of the entire model in 2017. At this time, DOT seeks review of some of the significant new elements added to the model after that review.

This subsequent peer review of the new elements was not complete at the time the proposal was published, and therefore materials concerning the peer reviewers' comments and NHTSA's responses were not available until later.²⁷⁸⁶ Although the comment period on the proposal had closed at that time, the agencies continued to receive comments on the new peer review materials, which they have considered in issuing this final rule.²⁷⁸⁷ Of course, the new elements of the modeling were also described in detail in the NPRM and commenters also directly commented on them in great detail. Thus, the public was fully apprised of all aspects of the modeling and had a robust opportunity to provide comment.

To the extent commenters are suggesting the Information Quality Act required a full peer review of all aspects of the CAFE model *prior* to the proposal, the agencies disagree.²⁷⁸⁸ Peer review of the new elements of the CAFE model helped ensure that the model is scientifically sound, and the peer reviewers provided feedback that helped improve the model and may help develop additional improvements to the model in the future. In this sense, the peer review of the new elements of the model functioned similarly to public comments from commenters with specific scientific expertise. Much of the feedback from the peer reviewers were in fact similar in nature to comments received from public commenters on the model. By engaging in both peer review and notice-and-comment procedures, the agencies ensured that they had information from a wide variety of sources, including those with specific expertise, to validate and improve the model.²⁷⁸⁹ The technical aspects of the model, including improvements made to the model

²⁷⁸⁶ NHTSA-2018-0067-0055 (July 2019 report).

²⁷⁸⁷ See, e.g., Center for Biological Diversity et al., NHTSA-2018-0067-12439; Environment America et al., NHTSA-2018-0067-12441.

²⁷⁸⁸ See, e.g., Center for Biological Diversity et al., NHTSA-2018-0067-12000; Environment America et al., NHTSA-2018-0067-12441.

²⁷⁸⁹ The timing of the peer review of new elements of the model also did not require a second cycle of notice and comment. See, e.g., *Alto Dairy v. Veneman*, 336 F.3d 560, 569-70 (7th Cir. 2003) ("The law does not require that every alteration in a proposed rule be reissued for notice and comment. If that were the case, an agency could 'learn from the comments on its proposals only at the peril of subjecting itself to rulemaking without end.'").

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

following the proposal, are described in detail in this final rule. Moreover, as the Center for Biological Diversity noted, the Information Quality Act does not create third-party rights.²⁷⁹⁰

The agencies also disagree that EPA needed to obtain a separate peer review of the CAFE model.²⁷⁹¹ The peer review addressed aspects of the model relevant to the analysis by both agencies under their respective statutory schemes. The agencies have expertise in their statutory requirements and discussed in detail both in the proposal and this final rule how the CAFE model was used to inform the decisionmaking under both EPCA and the CAA.

c) *Other APA comments*

Some commenters argued that EPA's Revised Determination was arbitrary and capricious.²⁷⁹² These commenters alleged that the record supporting the Revised Determination was not available for public review or comment, in violation of EPA's own regulations and the APA. These commenters also argued that, in making the Revised Determination, EPA ignored the findings and analysis in the TAR and the Technical Support Document and contradicted the pre-existing record without explanation. Commenters also contended that EPA did not provide a detailed basis for its Revised Determination that adequately assessed the required factors. Lastly, these commenters argued that the Revised Determination did not have a reasoned basis under the APA, particularly in light of the agency's change in position and the reliance interests at stake.

The agencies reject these arguments. EPA's Revised Determination was procedurally and substantively proper.

EPA regulations require that the Administrator determine whether the standards for MY 2022 to 2025 are "appropriate" under Section 202(a) of the Clean Air Act. 40 C.F.R. § 86.1818–12(h) ("Section 12(h)"). The Administrator's determination must be based upon a record that includes the following:

- (i) A draft Technical Assessment Report addressing issues relevant to the standard for the 2022 through 2025 model years;
- (ii) Public comment on the draft Technical Assessment Report;
- (iii) Public comment on whether the standards established for the 2022 through 2025 model years are appropriate under section 202(a) of the Clean Air Act; and

²⁷⁹⁰ Center for Biological Diversity et al., NHTSA-2018-0067-12000.

²⁷⁹¹ Center for Biological Diversity et al., NHTSA-2018-0067-12000.

²⁷⁹² See, e.g., comments from the States and Cities, Attachment 1, Docket No. NHTSA-2018-0067-11735, at 35-42; CBD et. al, Appendix A, Docket No. NHTSA-2018-0067-12000, at 214-228.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

(iv) Such other materials the Administrator deems appropriate.²⁷⁹³

In making his determination, the Administrator must consider relevant factors, including but not limited to:

(i) The availability and effectiveness of technology, and the appropriate lead time for introduction of technology;

(ii) The cost on the producers or purchasers of new motor vehicles or new motor vehicle engines;

(iii) The feasibility and practicability of the standards;

(iv) The impact of the standards on reduction of emissions, oil conservation, energy security, and fuel savings by consumers;

(v) The impact of the standards on the automobile industry;

(vi) The impacts of the standards on automobile safety;

(vii) The impact of the greenhouse gas emission standards on the Corporate Average Fuel Economy standards and a national harmonized program; and

(viii) The impact of the standards on other relevant factors.²⁷⁹⁴

The Administrator must “set forth in detail the bases for the determination..., including the Administrator’s assessment of each of the factors” identified.²⁷⁹⁵

The record for the Revised Determination included all of the required elements, including the draft TAR on which the public had the opportunity to comment. The record also included “[s]uch other materials the Administrator deems appropriate,” as expressly provided.²⁷⁹⁶ Since the Original Determination was made, EPA developed a “significant record” of relevant information, including additional data and assessments indicating that “[m]any of the key assumptions EPA relied upon” for the Original Determination “were optimistic or have significantly changed and thus no longer represent realistic assumptions.”²⁷⁹⁷ In determining that the current standards for MY 2022-2025 were not appropriate, “[t]he Administrator considered the complete record, including all comments provided on the reconsideration.”²⁷⁹⁸ Based on his consideration of “the complete record,” the Administrator then set forth the bases for the

²⁷⁹³ 40 CFR 86.1818-12(h)(2).

²⁷⁹⁸ 83 FR 16077, 16079 (Apr. 13, 2018).

determination, including his assessment of each of the enumerated factors, as required by Section 12(h).

The public has had multiple opportunities to comment on the record supporting the Revised Determination. The draft TAR was available for public comment. The Proposed Determination was available for public comment. The notice declaring EPA's intention to reconsider the Original Determination was available for public comment, and EPA held a public hearing on the matter. The SAFE Rule proposal itself was available for public comment, and there were three public hearings on it. The agencies have considered all the comments that were submitted in promulgating this final rule. No further opportunity for public comment is required.²⁷⁹⁹

EPA did not ignore the findings and analysis in the draft TAR and the Technical Support Document in issuing the Revised Determination, as these comments contend. Indeed, in the Revised Determination, the agency noted instances in which the draft TAR did not consider certain evidence or when assumptions and projections from the draft TAR had not been borne out.²⁸⁰⁰ In other instances, EPA relied on data from comments that had in turn relied on data from the draft TAR.²⁸⁰¹

Note also that some of these commenters' arguments have already been considered and dismissed by the D.C. Circuit in a challenge brought by many of the same commenters seeking to vacate the Revised Determination. Petitioners in that case alleged, as here, that EPA violated the procedural and substantive requirements imposed by Section 12(h) and that the Revised Determination was arbitrary and capricious under the Administrative Procedure Act. In its ruling, the Court confirmed that "EPA has not erased the Draft Technical Assessment Report, Technical Support Document, or any of the other prior evidence it collected."²⁸⁰² The Revised Determination did not "eliminate any part of the existing administrative record."²⁸⁰³ Instead, the Revised Determination "simply announced its intention to revisit the information collected in

²⁷⁹⁹ See *City of Waukesha v. E.P.A.*, 320 F.3d 228, 245-46 (D.C. Cir. 2003).

²⁸⁰⁰ 83 FR 16077, 16082 (Apr. 13, 2018) ("Manufacturers of Emission Controls Association (MECA) noted that automakers have announced plans to adopt 48-volt mild hybrids at a faster rate than originally planned and commented on new technologies that will be in production prior to 2021 but were not considered in the draft TAR, including dynamic cylinder deactivation, variable compression ratio and electric boost."); *id.* ("The petroleum industry noted that high octane fuel is available today for vehicles that require it and commented that EPA has no basis for including octane number as a factor in the Mid-term Evaluation because it was not considered in the prior rulemakings or the draft TAR."); *id.* at 16085 ("With respect to energy security, the situation of the United States is dramatically different than it was at the time the 2012 standards were promulgated, and even significantly different from its situation in 2016 when the draft TAR was developed.").

²⁸⁰¹ See, e.g., 83 FR 16077, 16083 (Apr. 13, 2018) ("The Alliance referenced work by Ford suggesting that the standards would reduce sales volumes by four percent using cost estimates from the draft TAR.").

²⁸⁰² *California v. EPA*, 940 F.3d 1342, 1351 (D.C. Cir. 2019).

²⁸⁰³ *Id.*

those earlier proceedings, along with new information gathered since then, to devise the standards that it finds appropriate.”²⁸⁰⁴

The D.C. Circuit also reaffirmed EPA’s authority to change the previous standards, provided that it offers a “reasoned basis” for departing from the facts and circumstances that underlay the previous standards when they were set in 2012.²⁸⁰⁵ By detailing the new evidence that was considered and the changed circumstances that have developed since the previous standards were promulgated, the agencies have provided the necessary “reasoned basis” for the new standards throughout this rule.

EPA, like any agency, is not bound to adhere to conclusions based on outdated information. Indeed, the regulation provides that in making the appropriateness determination, the Administrator must “consider the information available,” not just the information that was available in the past.²⁸⁰⁶ And agencies always have authority under the Administrative Procedure Act to revisit previous decisions in light of new facts, as long as they provide notice and an opportunity for comment—as the agencies did here. Indeed, it is the best practice to do so when changed circumstances so warrant.²⁸⁰⁷

“Changing policy does not, on its own, trigger an especially ‘demanding burden of justification.’”²⁸⁰⁸ “Agencies are free to change their existing policies as long as they provide a reasoned explanation for the change.”²⁸⁰⁹ Providing this explanation “would ordinarily demand that [the agency] display awareness that it *is* changing position.”²⁸¹⁰ Beyond that, however, “[w]hen an agency changes its existing position, it ‘need not always provide a more detailed justification than what would suffice for a new policy created on a blank slate.’”²⁸¹¹ The agency “need not demonstrate to a court’s satisfaction that the reasons for the new policy are *better* than the reasons for the old one.”²⁸¹² For instance, “evolving notions” about the appropriate balance of varying policy considerations constitute sufficiently good reasons for a change in position.²⁸¹³ A change in policy is “well within an agency’s discretion”: agencies are permitted to conduct a

“reevaluation of which policy would be better in light of the facts,” without “rely[ing] on new facts.”²⁸¹⁴

To be sure, providing “a more detailed justification” is appropriate in some cases.²⁸¹⁵ But when “a more detailed justification” is needed, all that is required is for the agency to explain how “new information arising after” the previous determination “informed its conclusion” that a change was appropriate: “explanations relying on new data are sufficient to satisfy the more detailed explanatory obligation.”²⁸¹⁶ As one of the critical comments itself noted, “[a]gencies must use ‘the best information available’ in reaching their conclusions, and cannot lawfully rely on outdated information as circumstances change.”²⁸¹⁷ Indeed, the Original Determination recognized that stage in the process was designed to be based on “the latest available data and information.”²⁸¹⁸ Accordingly, when new information became available, the agencies relied on it expressly, resulting in a fully-explained change in their analysis and ultimately their conclusions.

While “[i]t would be arbitrary or capricious to ignore such matters,”²⁸¹⁹ the agencies have not ignored them. EPA satisfied these standards in the Revised Determination. The agencies jointly issued a notice publicly announcing EPA’s intention to reconsider the Original Determination.²⁸²⁰ And the Revised Determination expressly and repeatedly acknowledged that it represented a change from the Original Determination, appropriately justifying the change by citing shifts in policy priorities or new facts and changed circumstances that became apparent since the Original Determination.²⁸²¹ The agencies are fully cognizant of the facts and circumstances that have changed since the Original Determination, expressly acknowledged

them in the Revised Determination and SAFE Rule NPRM, and adapted to accept them now in the final rule.

Several commenters also invoked requests to the agencies under the Freedom of Information Act (“FOIA”) regarding material sought in connection with the rulemaking.²⁸²² These comments ranged from simple references to existing FOIA requests to the agencies, to the actual submission of the FOIA requests as a comment posted to the rulemaking docket.²⁸²³ These commenters sought a variety of information, which included calendars and internal correspondence of specific agency personnel, communications with non-governmental stakeholders, and technical materials and clarifications relating to aspects of the agencies’ analysis.²⁸²⁴

To the extent these requests sought substantive material, those matters are addressed in other sections herein that pertain to the respective underlying issues implicated. Although the submission of FOIA requests through an online rulemaking docket is a very unusual form of submitting a FOIA request to an agency, the agencies nevertheless processed the comments that requested materials by invoking FOIA as formal FOIA requests. As such, once identified, those comments were forwarded to the agencies’ respective FOIA offices, which commenced the intake process of the letters as FOIA requests. In turn, the agencies’ FOIA offices transmitted receipt acknowledgement letters to the requestors and conducted searches for the applicable material. The agencies responded to the requestors by producing the responsive non-exempt records identified, applying the appropriate FOIA standards applicable to the records and requests. Like all other typical FOIA requests, the requestors were provided with an opportunity to administratively appeal the FOIA decision and, if desired, subsequently seek judicial review of the agencies’ decisions. Several commenters availed themselves of this procedure.²⁸²⁵

Thus, the agencies fully satisfied their obligations under the governing FOIA provisions. In fact, other commenters noted the agencies’ responses to these FOIA requests and incorporated information disclosed in the responses into their comments.²⁸²⁶ Moreover, several of the FOIA requests submitted as comments requested information that had already been published on the agencies’ websites for the rulemaking or in the rulemaking dockets.

²⁸²⁵ See generally, e.g., New York v. U.S. Env’tl. Prot. Agency and Nat’l Highway Traffic Safety Admin., Case No. 1:19-cv-00712 (S.D.N.Y.) (FOIA litigation concerning a FOIA request submitted as a comment from the Office of the Attorney General of the State of New York, NHTSA-2018-0067-3613).

²⁸²⁶ See James H. Stock, Kenneth Gillingham & Wade Davis, EPA-HQ-OAR-2018-0283-6220, at p. 6.

Although the agencies fulfilled their obligations under all applicable FOIA law, the agencies also stress that FOIA compliance is wholly irrelevant to conformity to governing APA standards in the rulemaking process. FOIA arises from an independent statutory framework, which contains unique provisions for judicial review.²⁸²⁷ These provisions for judicial review provide “an adequate form of relief” such that the APA is not typically even an appropriate mechanism to seek the disclosure of further information requested under FOIA.²⁸²⁸ Likewise, the APA’s principles governing rulemaking procedures, including disclosures of information for such rulemakings, exist as autonomous statutory and jurisprudential concepts totally untethered from the principles of disclosure under FOIA.

Similarly, as an independent statutory framework from the APA, the susceptibility of materials and records for production under FOIA has no bearing on whether such materials should have been made public under the APA as part of a rulemaking. The scope of materials for production under FOIA arises from the Agency’s reasonable interpretation of the language of the FOIA request, as well as the exemptions potentially applicable to the records under the applicable FOIA statutes and implementing regulations.²⁸²⁹ In contrast, in an APA review of rulemaking procedures, separate standards exist to govern the scope of materials an agency must make available during the rulemaking process.²⁸³⁰ Thus, records may be responsive to a FOIA request, but not appropriate for publication under the APA—even if the FOIA request concerns the proposed rule in question. The FOIA requests at issue here are illustrative of this distinction. For example, one of the specific FOIA requests identified by commenters describes the requests as pertaining to the NPRM, but seeks Outlook calendars of DOT and NHTSA personnel.²⁸³¹ While such materials may be responsive to the underlying FOIA requests, which expressly mention the calendars, an employee’s entire list of calendar appointments—including appointments unrelated to the rulemaking—is clearly not contemplated by the APA as material necessary for publication along with a proposed rule. Thus, while the agencies sought to comply with their independent statutory obligations under FOIA, to the extent commenters invoke purported FOIA noncompliance, the agencies consider such arguments irrelevant to the rulemaking analysis. Likewise, any production of records in connection with any FOIA request that invokes the proposed rule is not a recognition by the agencies that the material should have also been made available during the rulemaking under the APA.

Several commenters also criticized the agencies, and specifically the EPA, for not publishing an updated version of the Optimization Model for Reducing Emissions of Greenhouse

²⁸³¹ See *Environmental Defense Fund, NHTSA-2018-0067-12397*.

Gases from Automobiles (“OMEGA”) along with the proposed rule.²⁸³² As described in further detail in Section IV herein, OMEGA is a fleet compliance model developed by the EPA and used in previous rulemakings. While many commenters raised technical arguments comparing the OMEGA model to the CAFE Model utilized in this rulemaking, such technical analysis and comments are addressed elsewhere in this final rule analysis. *See* Section IV. Likewise, while several comments refer to FOIA requests for OMEGA model materials, the Agencies’ discussion of FOIA comments are addressed above.

Most other commenters who raised more procedural arguments concerning the unavailability of an updated version of the OMEGA model argued that an updated version of the model should have been released because the EPA utilized the model during an interagency review of the proposed rule.²⁸³³ In considering these comments, the agencies emphasize that neither NHTSA, the EPA, nor any other interagency reviewer relied upon the OMEGA model for the preparation of either the proposed or the final versions of the SAFE Vehicles Rule. Instead, as clearly expressed in rulemaking descriptions and documents accompanying both this final rule and the proposed rule, the agencies relied on a separate model to perform the analysis that helped to inform the agencies regarding potential effects of various fuel economy standards. This independent model, the CAFE Model, was developed by the Department of Transportation’s Volpe National Transportation Systems Center.

In fact, most commenters discussing the OMEGA model understood and expressly acknowledged that the agencies relied upon the CAFE Model rather than the OMEGA model for this rulemaking.²⁸³⁴ Several commenters even paradoxically argued *both* that the agencies unreasonably failed to utilize the OMEGA model *and* that the agencies denied meaningful opportunity for comment by utilizing but failing to publish an updated OMEGA model.²⁸³⁵ Nevertheless, the analysis and universe of documents published for the proposed rule made abundantly clear that the CAFE Model—not the OMEGA model—performed the applicable analysis for this rulemaking. Likewise, the agencies’ proposed rule published voluminous analyses and supporting documents to describe the CAFE Model and explain the underlying methodologies incorporated into the model’s operation for this rulemaking. The agencies also released the full version of the CAFE Model employed in this rulemaking, as well as its respective inputs and outputs, in order to provide commenters with ample opportunities to understand the model’s function and operation.

The extensive comments on the modeling conducted for this rulemaking confirm that the agencies provided the public with sufficient information to comment on the modeling process for the rulemaking. Comments regarding the OMEGA and CAFE models were expansive, spanning

²⁸³⁵ *See, e.g.*, Environmental Defense Fund, NHTSA-2018-0067-12108.

hundreds of pages of technical analysis and submissions from a variety of commenters. Many of these comments even consisted of detailed and technical comparisons of the CAFE model used in this rulemaking with past versions of OMEGA models used for prior rulemakings.²⁸³⁶ Even if certain of these commenters disagreed with the Agencies' ultimate approach to the modeling, they evidently understood the applicable methodologies and performance of the CAFE Model for this rulemaking sufficiently to substantively engage with the Agencies on these topics through their comments. Therefore, the agencies consider the detailed comments on the OMEGA and CAFE models as clear indicia that the extensive information, materials, and explanations provided by the agencies in the proposed rule enabled significant opportunity for the public to comment on the modeling for the rule.

To the extent that commenters allege an insufficient opportunity to comment by claiming that the EPA actually utilized the OMEGA model in the rulemaking process, the agencies consider such comments unfounded.²⁸³⁷ The agencies did not rely on the OMEGA model during the rulemaking process, including during the analysis for the proposed and final rules. In past rulemakings, the EPA developed a complete final version of the OMEGA model to perform the rulemaking analysis. Here, the EPA did not even finalize a completed updated version of the OMEGA model, much less rely on such a model in the course of the rulemaking. Therefore, no completed version of an updated OMEGA model even existed for the agencies to publish as part of the notice of proposed rulemaking.

To the extent commenters argue that the EPA *should* have updated the model for this rulemaking, the APA's facilitation of a meaningful opportunity to comment neither requires nor contemplates a mandate that the agencies develop computational modeling alternatives for the public, which were not even incorporated into the agencies' own rulemaking analysis.²⁸³⁸ In fact, doing so would actually detract from the notice and comment process because it would convolute the rulemaking docket and inhibit the public's ability to identify the modeling materials actually used in the rulemaking process. Thus, such extraneous materials would only dilute the rulemaking docket with voluminous and complex materials, such as modeling files, input files, and statistical figures, that had no influence on the rulemaking in question. Indeed, several commenters already claimed that the voluminous and complex supporting materials in the rulemaking docket required significant time for review, so the introduction of extensive totally extraneous material would have been only counterproductive to the process.²⁸³⁹

Moreover, requiring the EPA to perform the work necessary to fully update the OMEGA model solely for a public release—when it did not otherwise intend to consider the model in the

²⁸³⁶ See, e.g., California Air Resources Board, NHTSA-2018-0067-11873; Union of Concerned Scientists, NHTSA-2018-0067-12039; Alliance of Automobile Manufacturers, NHTSA-2018-0067-12073.

²⁸³⁷ See, e.g., Center for Biological Diversity, NHTSA-2018-0067-12000.

²⁸³⁸ See, e.g., Center for Biological Diversity et al., NHTSA-2018-0067-12000.

²⁸³⁹ See, e.g., Institute for Policy Integrity, NHTSA-2018-0067-5641; Northeast States for Coordinated Air Use Management, NHTSA-2018-0067-2158.

rulemaking—would divert valuable and finite agency resources away from actual rulemaking analyses in favor of efforts that further no progress in the rulemaking.²⁸⁴⁰ Such an approach would detract from the agencies’ opportunities to devote time to other considerations that actually influenced the rulemaking, such as the substantive analysis incorporated into the proposed rule and the drafting of extensive language to explain to the public the methodologies applied by the agencies for the proposal. Such an inefficient allocation of resources undermines both the rulemaking process envisioned by the APA and the very notice and comment procedures utilized by these commenters.

Several commenters also argued that even if the agencies did not rely on the model for this rulemaking, the OMEGA model still informed the EPA’s analysis and interagency review by providing general background experience in regulating greenhouse gas emissions—either through the agency’s work with prior versions of the model or ongoing efforts to update the OMEGA model for purposes unrelated to this rulemaking. However, even assuming the model provided background experience to the EPA in regulating in this arena, federal jurisprudence makes clear that “[t]he Administrative Procedure Act does not require that every bit of background information used by an administrative agency be published for public comment.” *See B. F. Goodrich Co. v. Dep’t of Transp.*, 541 F.2d 1178, 1184 (6th Cir. 1976). This is particularly the case when, as here, “[t]he basic data upon which the agency relied in formulating the regulation was available...for comment.” *Id.*; *see also Am. Min. Cong. v. Marshall*, 671 F.2d 1251, 1261 (10th Cir. 1982) (“These documents consist of background information and data as well as several internal memoranda. There is nothing to indicate that the Secretary actually relied on any of these documents in promulgating the rule or that the data they contain was critical to the formulation of the rule.”). In fact, publishing such background information not only exceeds the requirements of the APA, but would actually affirmatively undermine the APA’s notice and comment procedure. If every piece of information ever referenced by the agencies or upon which the Agencies drew regulatory experience were required to be published, rulemaking dockets would expand to an absurd scope of nearly infinite materials, spanning arguably back to even the school textbooks the rulemaking personnel used to learn the underlying disciplines employed in the rulemaking analysis. Clearly such a scope would frustrate rather than further the provision of proper notice to the public about a proposed rule.²⁸⁴¹

Moreover, even assuming the premise of several commenters’ challenges—that the EPA consulted updates to the OMEGA model during the interagency review—such a predicate still would not require the publication of the model during the rulemaking process.²⁸⁴² As the

²⁸⁴⁰ *See, e.g.*, Environmental Defense Fund, NHTSA-2018-0067-12108.

²⁸⁴¹ To the extent commenters seek to understand the manner in which the OMEGA model informed prior rulemaking efforts, the EPA has released the full versions of prior OMEGA models and applicable materials along with the prior rulemakings. In fact, several commenters referenced such materials in submitting detailed comments comparing the CAFE Model with the OMEGA model. Manufacturers of Emission Controls Association, NHTSA-2018-0067-11994. Thus, any commenters that were interested in such extraneous background information had ample opportunity to access the material.

²⁸⁴² *See, e.g.*, Environmental Defense Fund, NHTSA-2018-0067-12406.

agencies have made clear, the OMEGA model did not affect any part of the rule, including the methodologies and analysis underlying the formulation of the rule. Therefore, even if consulted, the OMEGA model would exist as, at most, supplementary material which had no influence on the rulemaking methodologies, all of which were fully disclosed. *See, e.g., Chamber of Commerce of U.S. v. S.E.C.*, 443 F.3d 890, 900 (D.C. Cir. 2006) (“When the agency relies on supplementary evidence without a showing of prejudice by an interested party, the procedural requirements of the APA are satisfied without further opportunity for comment, provided that the agency’s response constitutes a logical outgrowth of the rule initially proposed”) (internal citations omitted).

3. National Environmental Policy Act

As discussed above, EPCA requires NHTSA to determine the level at which to set CAFE standards for each model year by considering the four factors of technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy. The National Environmental Policy Act (NEPA) directs that environmental considerations be integrated into that process.²⁸⁴³ To explore the potential environmental consequences of this rulemaking action, NHTSA prepared a Draft Environmental Impact Statement (“DEIS”) for the NPRM and a Final Environmental Impact Statement (“FEIS”) for the final rule. The purpose of an EIS is to “provide full and fair discussion of significant environmental impacts and [to] inform decisionmakers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment.”²⁸⁴⁴

As explained in the NPRM, NEPA is “a procedural statute that mandates a process rather than a particular result.”²⁸⁴⁵ The agency’s overall EIS-related obligation is to “take a ‘hard look’ at the environmental consequences before taking a major action.”²⁸⁴⁶ Significantly, “[i]f the adverse environmental effects of the proposed action are adequately identified and evaluated, the agency is not constrained by NEPA from deciding that other values outweigh the environmental costs.”²⁸⁴⁷ The agency must identify the “environmentally preferable” alternative but need not adopt it.²⁸⁴⁸ “Congress in enacting NEPA . . . did not require agencies to elevate environmental concerns over other appropriate considerations.”²⁸⁴⁹ Instead, NEPA requires an agency to develop and consider alternatives to the proposed action in preparing an EIS.²⁸⁵⁰ The statute and

²⁸⁴³ NEPA is codified at 42 U.S.C. 4321–47. The Council on Environmental Quality (CEQ) NEPA implementing regulations are codified at 40 CFR parts 1500–08.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

implementing regulations do not command the agency to favor an environmentally preferable course of action, only that it make its decision to proceed with the action after taking a hard look at the potential environmental consequences and consider the relevant factors in making a decision among alternatives.²⁸⁵¹

NHTSA received many comments on the DEIS. Among the comments received, many commenters stated that the baseline/no-action standards were the environmentally preferable alternative and argued that the environmental benefits of the proposal were (1) insufficient and/or (2) incorrectly assessed in a variety of ways. Comments regarding the environmental analyses presented in this preamble are addressed in Section VI above, while those regarding the DEIS are addressed in Chapter 10 of the FEIS.

When preparing an EIS, NEPA requires an agency to compare the potential environmental impacts of its proposed action and a reasonable range of alternatives. In the DEIS, NHTSA analyzed a No Action Alternative and eight action alternatives. In the FEIS, NHTSA analyzed the same No Action Alternative and seven action alternatives, including a new alternative (the Preferred Alternative) within the range of the alternatives considered in the DEIS and FEIS.²⁸⁵² The alternatives represent a range of potential actions the agency could take, and they are described more fully in Section V above, below in this section, and Chapter 2 of the FEIS. The environmental impacts of these alternatives, in turn, represent a range of potential environmental impacts that could result from NHTSA's setting maximum feasible fuel economy standards for passenger cars and light trucks.

To derive the direct and indirect impacts of the action alternatives, NHTSA compared each action alternative to the No Action Alternative, which reflects baseline trends that would be expected in the absence of any further regulatory action other than finalizing the augural standards. More specifically, the No Action Alternative in the DEIS and FEIS assumed that NHTSA would not amend the CAFE standards for MY 2021 passenger cars and light trucks. In addition, the No Action Alternative assumed that NHTSA would finalize the MY 2022-2025 augural CAFE standards that were described in the 2012 final rule. Finally, for purposes of its analysis, NHTSA assumed that the MY 2025 augural standards would continue indefinitely. The augural standards also serve as a proxy for EPA's CO₂ standards for MYs 2022-2025, which were also finalized in the 2012 final rule. The No Action Alternative provides an analytical baseline against which to compare the environmental impacts of other alternatives presented in the EIS.²⁸⁵³

²⁸⁵¹ 40 CFR 1505.2(b).

²⁸⁵² In its scoping notice, NHTSA indicated that the action alternatives analyzed would bracket a range of reasonable annual fuel economy standards, allowing the agency to select an action alternative in its final rule from any stringency level within that range. 82 FR 34740, 34743 (July 26, 2017).

²⁸⁵³ See 40 CFR 1502.2(e), 1502.14(d). CEQ has explained that "[T]he regulations require the analysis of the no action alternative even if the agency is under a court order or legislative command to act. This analysis provides a benchmark, enabling decision makers to compare the magnitude of environmental effects of the action alternatives

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

For the DEIS, NHTSA analyzed eight action alternatives, Alternatives 1 through 8, which ranged from amending the MY 2021 standards to match the MY 2020 standards and holding those standards flat for passenger cars and light trucks through MY 2026 (Alternative 1) to maintaining the existing MY 2021 standards and subsequently requiring average annual increases in fuel economy by 2.0 percent (passenger cars) and 3.0 percent (light trucks) (Alternative 8). The action alternatives analyzed in the DEIS also reflected different options regarding air conditioning efficiency and off-cycle technology adjustment procedures, with some alternatives phasing out these adjustments in MYs 2022-2026. For the FEIS, NHTSA analyzed seven action alternatives, Alternatives 1 through 7, which range from amending the MY 2021 standards to match the MY 2020 standards and holding those standards flat for passenger cars and light trucks through MY 2026 (Alternative 1) to maintaining the existing MY 2021 standards and subsequently requiring average annual increases in fuel economy by 2.0 percent (passenger cars) and 3.0 percent (light trucks) (Alternative 7) from year to year. The primary differences between the action alternatives for the DEIS and FEIS is that the FEIS did not analyze alternatives that phased out the air conditioning efficiency and off-cycle technology adjustments (see Section V above for further discussion), and the FEIS added an alternative under which fuel economy increased at 1.5 percent per year for both cars and light trucks (Alternative 3). Both of the ranges of action alternatives, as well as the No Action Alternative, in the DEIS and FEIS encompassed a spectrum of possible standards NHTSA could determine was maximum feasible based on the different ways the agency could weigh EPCA's four statutory factors. Throughout the FEIS, estimated impacts were shown for all of these action alternatives, as well as for the No Action Alternative. For a more detailed discussion of the environmental impacts associated with the alternatives, *see* Chapters 3-8 of the FEIS, as well as Section VII above.

NHTSA's FEIS describes potential environmental impacts to a variety of resources, including fuel and energy use, air quality, climate, land use and development, hazardous materials and regulated wastes, historical and cultural resources, noise, and environmental justice. The FEIS also describes how climate change resulting from global carbon emissions (including CO₂ emissions attributable to the U.S. light duty transportation sector under the alternatives considered) could affect certain key natural and human resources. Resource areas are assessed qualitatively and quantitatively, as appropriate, in the FEIS, and the findings of that analysis are summarized here.²⁸⁵⁴

[See 40 CFR 1502.14(c).] . . . Inclusion of such an analysis in the EIS is necessary to inform Congress, the public, and the President as intended by NEPA. [See 40 CFR 1500.1(a).]" Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, 46 FR 18026 (Mar. 23, 1981).

²⁸⁵⁴ The impacts described in this section come from NHTSA's FEIS, which is being publicly issued simultaneously with this final rule. As described in Section VII.A.4.c.1 above, the FEIS is based on "unconstrained" modeling rather than "standard setting" modeling; NHTSA conducts modeling both ways in order to reflect the various statutory requirements of EPCA and NEPA. The preamble employs the "standard setting" modeling in order to ensure that the decision-maker does not consider things that EPCA/EISA prohibit, but as a result, the impacts reported here may differ from those reported elsewhere in this preamble. However, NHTSA considers the impacts reported in the FEIS, in addition to the other information presented in this preamble, as part of its decisionmaking process.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

As the stringency of the alternatives increases, total U.S. passenger car and light truck fuel consumption for the period of 2020 to 2050 decreases. Total light-duty vehicle fuel consumption from 2020 to 2050 under the No Action Alternative is projected to be 3,371 billion gasoline gallon equivalents (GGE). Light-duty vehicle fuel consumption from 2020 to 2050 under the action alternatives is projected to range from 3,598 billion GGE under Alternative 1 to 3,456 billion gallons GGE under Alternative 7. Under the Alternative 3, light-duty vehicle fuel consumption from 2020 to 2050 is projected to be 3,571 GGE. All of the action alternatives would increase fuel consumption compared to the No Action Alternative, with fuel consumption increases that range from 226 billion GGE under Alternative 1 to 85 billion GGE under Alternative 7.

The relationship between stringency and air pollutant emissions is less straightforward, reflecting the complex interactions among the tailpipe emissions rates of the various vehicle types, the technologies assumed to be incorporated by manufacturers in response to the CAFE standards, upstream emissions rates, the relative proportions of gasoline and diesel in total fuel consumption, and changes in VMT from the rebound effect. In general, emissions of criteria and toxic air pollutants increase across all action alternatives, with some exceptions. Further, the action alternatives would result in increased incidence of PM_{2.5}-related adverse health impacts (including increased incidences of premature mortality, acute bronchitis, respiratory emergency room visits, and work-loss days) due to the emissions increases.²⁸⁵⁵

For CO (in 2025), NO_x (in 2025), and SO₂, emissions generally decrease under the action alternatives compared to the No Action Alternative. For CO in 2025, the largest decrease occurs under Alternative 1 and the emissions decreases get smaller from Alternative 1 through Alternative 7. For NO_x in 2025, the largest decrease occurs under Alternative 6. For SO₂ in 2025, the largest decrease occurs under Alternative 6; however, SO₂ emissions under Alternative 7 are greater than under the No Action Alternative. For SO₂ in 2035, the largest decrease occurs under Alternative 2. For SO₂ in 2050, the largest decrease occurs under Alternative 1 and the emissions decreases get smaller from Alternative 1 through Alternative 7. Across all criteria pollutants, action alternatives, and analysis years, the smallest decrease in emissions is less than 0.1 percent and occurs for NO_x under Alternative 7 in 2025; the largest decrease is 12 percent and occurs for SO₂ under Alternative 2 in 2050.

For CO (in 2035 and 2050), NO_x (in 2035 and 2050), PM_{2.5}, and VOCs, emissions show increases across action alternatives compared to the No Action Alternative, with the largest increases occurring under Alternative 1 (except CO in 2035, for which the largest increase occurs under Alternative 4). The emissions increases get smaller from Alternative 1 through Alternative 7. Exceptions to this trend are for PM_{2.5} and VOCs in 2025, which show the smallest emissions increase under Alternative 6. Across all criteria pollutants, action

²⁸⁵⁵ As discussed in Section X.E.1, NHTSA also performed a national-scale photochemical air quality modeling and health benefit assessment for the FEIS, which is included as Appendix E. This analysis affirms the estimates that appeared in the DEIS and explains conclusions that may be drawn from the FEIS air quality discussion.

alternatives, and analysis years, the smallest increase in emissions is 0.1 percent and occurs for SO₂ under Alternative 7 in 2025; the largest increase is 12 percent and occurs for VOCs under Alternative 1 in 2050.

Under each action alternative in 2025 compared to the No Action Alternative, decreases in emissions would occur for all toxic air pollutants except for DPM, for which emissions would increase by as much as 2 percent. For 2025, the largest relative decreases in emissions would occur for 1,3-butadiene, for which emissions would decrease by as much as 0.5 percent. Percentage reductions in emissions of acetaldehyde, acrolein, benzene, and formaldehyde would be less. Under each action alternative in 2035 and 2050 compared to the No Action Alternative, increases in emissions would occur for all toxic air pollutants. The largest relative increases in emissions would occur for DPM, for which emissions would increase by as much as 9 percent. Percentage increases in emissions of acetaldehyde, acrolein, benzene, 1,3-butadiene, and formaldehyde would be less.

In addition, the action alternatives would result in increased incidence of PM_{2.5}-related adverse health impacts due to the emissions increases. Increases in adverse health outcomes include increased incidences of premature mortality, acute bronchitis, respiratory emergency room visits, and work-loss days. In 2025 and 2035, all action alternatives except for Alternative 6 would result in increased adverse health impacts nationwide compared to the No Action Alternative as a result of increases in emissions of NO_x, PM_{2.5}, and DPM. The increases in adverse health impacts are largest for the least stringent alternative (Alternative 1). The increases get smaller from Alternative 1 to Alternative 4, get larger from Alternative 4 to Alternative 5, then smaller from Alternative 5 to Alternative 6, and larger again from Alternative 6 to Alternative 7. In 2050, all action alternatives would result in decreased adverse health impacts nationwide compared to the No Action Alternative as a result of decreases in emissions of SO_x. The decreases in adverse health impacts get smaller from Alternative 1 to Alternative 7.

The action alternatives would increase U.S. passenger car and light truck fuel consumption and CO₂ emissions compared with the No Action Alternative, resulting in minor increases to the anticipated increases in global CO₂ concentrations, temperature, precipitation, and sea level, and minor decreases in ocean pH that would otherwise occur, as described below. They could also, to a small degree, increase the impacts and risks of climate change. Uncertainty exists regarding the magnitude of impact on these climate variables, as well as to the impacts and risks of climate change. Still, the impacts of the action alternatives on global mean surface temperature, precipitation, sea level, and ocean pH would be extremely small in relation to global emissions trajectories. This is because of the global and multi-sectoral nature of climate change. These effects would be small, would occur on a global scale, and would not disproportionately affect the United States.

According to the FEIS, passenger cars and light trucks are projected to emit 85,900 million metric tons of carbon dioxide (MMTCO₂) from 2021 through 2100 under the No Action Alternative. Alternative 1 would increase these emissions by 10 percent through 2100 (approximately 8,800 MMTCO₂). Alternative 7 would increase these emissions by 4 percent through 2100 (approximately 3,100 MMTCO₂). Emissions increases would be highest under

Alternative 1 and would decrease across the action alternatives, with emissions being the lowest under the No Action Alternative.

In the FEIS, NHTSA presented two different analyses based on these emissions changes to illustrate potential impacts to certain climate variables. In the first analysis, to represent the direct and indirect impacts of this action, NHTSA used the Global Change Assessment Model (GCAM) Reference scenario (i.e., future global emissions assuming no additional climate policy [“business-as-usual”]) to represent the reference case emissions scenario. Under that analysis, total global CO₂ emissions from all sources are projected to be 4,950,865 MMTCO₂ under the No Action Alternative from 2021 through 2100, which means that the action alternatives are expected to increase global CO₂ emissions between 0.06 (Alternative 7) and 0.17 (Alternative 1) percent by 2100. The estimated CO₂ concentrations in the atmosphere for 2100 would range from 789.89 parts per million (ppm) under Alternative 1 to approximately 789.11 ppm under the No Action Alternative, indicating a maximum atmospheric CO₂ increase of approximately 0.78 ppm compared to the No Action Alternative.

Changes in CO₂ emissions translate to changes in global mean surface temperature, sea levels, global mean precipitation, and ocean pH, among other things. Under the first analysis, global mean surface temperature is projected to increase by approximately 3.48°C (6.27°F) under the No Action Alternative by 2100. Implementing the lowest-emissions action alternative (Alternative 7) would increase this projected temperature rise by 0.001°C (0.002°F), while implementing the highest-emissions alternative (Alternative 1) would increase projected temperature rise by 0.003°C (0.005°F). Projected sea-level rise in 2100 ranges from a low of 76.28 centimeters (30.03 inches) under the No Action Alternative to a high of 76.35 centimeters (30.06 inches) under Alternative 1. Alternative 1 would result in an increase in sea level equal to 0.07 centimeter (0.03 inch) by 2100 compared with the level projected under the No Action Alternative, compared to an increase under Alternative 7 of 0.02 centimeter (0.001 inch) compared with the No Action Alternative. Global mean precipitation is anticipated to increase by 5.85 percent by 2100 under the No Action Alternative. Under the action alternatives, this increase in precipitation would be increased further by 0.01 percent. Finally, ocean pH in 2100 is anticipated to be 8.2715 under Alternative 7, about 0.0001 less than the No Action Alternative. Under Alternative 1, ocean pH in 2100 would be 8.2712, or 0.0004 less than the No Action Alternative.

In the second analysis, NHTSA used the GCAM6.0 scenario instead of the default scenario to represent the reference case emissions scenario. The GCAM6.0 scenario assumes a moderate level of global GHG reductions and corresponds to stabilization, by 2100, of total radiative forcing and associated CO₂ concentrations at roughly 678 ppm. By assuming a moderate level of global GHG reduction, NHTSA attempts to capture the cumulative impacts of this action (i.e., the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions). In the FEIS, NHTSA documented a number of domestic and global actions that indicate that a moderate reduction in the growth rate of global GHG emissions is reasonably foreseeable in the future.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

Under the second analysis, compared with projected total global CO₂ emissions of 4,044,005 MMTCO₂ from all sources from 2021 to 2100, the incremental impact of this rulemaking is expected to increase global CO₂ emissions between 0.08 (Alternative 7) and 0.22 (Alternative 1) percent by 2100. Estimated atmospheric CO₂ concentrations in 2100 range from a low of 687.3 ppm under the No Action Alternative to a high of 688.04 ppm under Alternative 1. Alternative 7, the lowest CO₂ emissions alternative, would result in CO₂ concentrations of 687.55 ppm, an increase of 0.26 ppm compared with the No Action Alternative. Global mean surface temperature increases for the action alternatives compared with the No Action Alternative in 2100 range from a low of 0.001°C (0.002°F) under Alternative 7 to a high of 0.004°C (0.007°F) under Alternative 1. Global mean precipitation is anticipated to increase by 4.77 percent by 2100 under the No Action Alternative. Under the action alternatives, this increase in precipitation would be increased further by 0.01 percent. Projected sea-level rise in 2100 ranges from a low of 70.22 centimeters (27.65 inches) under the No Action Alternative to a high of 70.30 centimeters (27.68 inches) under Alternative 1, indicating a maximum increase of sea-level rise of 0.07 centimeter (0.03 inch) by 2100. Sea-level rise under Alternative 7 would be 70.25 centimeters (27.66 inches), a 0.03 centimeter (0.01-inch) increase compared to the No Action Alternative. Ocean pH in 2100 is anticipated to be 8.2721 under Alternative 7, about 0.0001 less than the No Action Alternative. Under Alternative 1, ocean pH in 2100 would be 8.2719, or 0.0004 less than the No Action Alternative.

For several other resources, NHTSA is unable to provide a quantitative measurement of potential impacts. Instead, the FEIS presents a qualitative discussion on potential impacts. In most cases, NHTSA presents the findings of a literature review of scientific studies, such as in Chapter 6, where NHTSA provides a literature synthesis focusing on existing credible scientific information to evaluate the most significant lifecycle environmental impacts from some of the fuels, materials, and technologies that may be used to comply with the alternatives. In Chapter 7, NHTSA discusses land use and development, hazardous materials and regulated waste, historical and cultural resources, noise, and environmental justice. Finally, in Chapter 8, NHTSA discusses cumulative impacts related to energy, air quality, and climate change, and provides a literature synthesis of the impacts on key natural and human resources of changes in climate change variables. In these chapters, NHTSA concludes that impacts would be proportional to changes in emissions that would result under the alternatives. As a result, among the action alternatives, Alternative 1 would have the highest impact on these resources while Alternative 7 would have the lowest.

Based on the foregoing, NHTSA concludes from the FEIS that the No Action Alternative is the overall environmentally preferable alternative because, assuming full compliance were achieved regardless of the agency's assessment of the costs to industry and society, it would result in the largest reductions in fuel use and CO₂ emissions among the alternatives considered. In addition, the No Action Alternative would result in the lowest overall emissions levels of criteria air pollutants (with the exception of sulfur dioxide) and of the toxic air pollutants studied by NHTSA. Impacts on other resources (especially those described qualitatively in the FEIS) would be proportional to the impacts on fuel use and emissions, as further described in the FEIS,

with the No Action Alternative expected to have the fewest negative impacts.²⁸⁵⁶ Although the CEQ regulations require NHTSA to identify the environmentally preferable alternative,²⁸⁵⁷ the agency need not adopt it, as described above. The following section (Section VIII.B.4) explains how NHTSA balanced the relevant factors to determine which alternative represented the maximum feasible standards, including why NHTSA does not believe that the environmentally preferable alternative is maximum feasible.

4. Evaluating the EPCA factors and other considerations to arrive at the proposed standards

In the NPRM, NHTSA began its discussion of the tentative balancing of factors by explaining that “NHTSA well recognizes that the decision it proposes to make in today’s NPRM is different from the one made in the 2012 final rule that established standards for MY 2021 and identified “augural” standard levels for MYs 2022-2025. Not only do we believe that the facts before us have changed, but we believe that those facts have changed sufficiently that the balancing of the EPCA factors and other considerations must also change. The standards we are proposing today reflect that balancing.”²⁸⁵⁸ NHTSA highlights this discussion at the outset in response to the number of commenters who claimed that NHTSA had not acknowledged or explained in the NPRM how or why the proposal was different from past work or policy decisions.

The NPRM balancing discussion went on to explore the definition of “to conserve” in the context of what “energy conservation” and “the need of the U.S. to conserve energy” should be interpreted to mean, in recognition of the major structural changes in global oil markets since EPCA was originally passed, and even since the 2012 final rule that set forth the augural standards. NHTSA examined these changes from both a demand perspective and a supply perspective. On the demand side, U.S. demand and global demand have both changed over time. The NPRM discussed the fact that the U.S. consumes a much smaller share of global oil output than it did at the CAFE program’s outset, both because U.S. fleet fuel economy has improved, and because other countries that were not major petroleum consumers in the 1970s have rapidly increased their share of consumption, and continue to do so. A more globalized market means that risk of price spikes is spread around—making the U.S. in particular less likely to bear a disproportionate burden of price spikes. The NPRM also discussed the decreasing energy intensity of the U.S. economy over time and the improving balance of payments in petroleum, including the likelihood that the U.S. is poised to become a net petroleum exporter in the near future. Related to the decreasing energy intensity of the U.S. economy, on the demand side, the NPRM discussed the proliferation of fuel-efficient vehicle options in the market in response to CAFE increases over time, and the fact that consumers who wish to purchase more fuel efficient vehicles have largely done so, and may continue to do so over time if they wish.

²⁸⁵⁶ Among the action alternatives considered, Alternative 7 would be the environmentally preferable alternative, as it is closest in stringency to the No Action Alternative.

²⁸⁵⁷ 40 CFR 1505.2(b).

²⁸⁵⁸ 83 FR at 43213.

On the supply side, the NPRM explained, vast increases in U.S. petroleum production, largely from shale formations, have introduced a major new stable supply into the global market. Shale oil production costs may be higher than the cost (for example, to OPEC members) to produce traditional oil, but that itself acts as a lever on global prices. Prices of goods like oil are affected by demand and supply—given that global demand trends increase relatively steadily, if OPEC States want to increase revenues by selling more of the total oil consumed globally, they have to try to control global supply volume by controlling production volumes (to avoid shale production increasing in response to higher prices). In short, the higher global prices trend, the more U.S. shale production increases in response, and as supply increases, prices fall. The NPRM discussed the responsiveness of U.S. shale production and suggested it could be higher than traditional producers in some instances. Traditional oil producers seeking to maintain market share have a new incentive to keep prices below a certain threshold, and U.S supply helps to buffer the impact of geopolitical events. The NPRM looked at then-current EIA oil price forecasts, under which U.S. gasoline prices were not forecast to exceed \$4/gallon through 2050, and acknowledged that while price shocks could still occur, NHTSA tentatively concluded that from the supply side, it is possible that the oil market conditions that created the price shocks in the 1970s may no longer exist.

In light of these changes in global oil markets, the NPRM tentatively concluded that many aspects of the need of the U.S. to conserve energy had improved enough over time to merit further consideration of what the need of the United States is to conserve oil today and going forward. With regard to environmental considerations, the NPRM returned to the definition of “to conserve” and suggested that differences of thousandths of a degree Celsius in 2100 resulting from higher levels of carbon dioxide emissions under the proposal as compared to the augural standards might not rise to the level of “wasteful,” given the other considerations discussed. With regard to consumer costs, the NPRM discussed the interplay of oil market conditions with prior arguments about consumer “myopia” with regard to the benefits of fuel savings, and tentatively concluded that U.S. consumers may be valuing fuel savings appropriately and purchasing the vehicles they want to purchase—i.e., that using CAFE standards as a tool to compel consumers to save money may not be necessary.

Given the discussion above, NHTSA tentatively concluded that the need of the U.S. to conserve energy may no longer function as assumed in previous considerations of what CAFE standards would be maximum feasible. In that discussion, NHTSA stated that the overall risks associated with the need of the U.S. to conserve oil have entered a new paradigm with the risks substantially lower today and projected into the future than when CAFE standards were first issued and in the recent past. NHTSA explained that the effectiveness of CAFE standards in reducing the demand for fuel combined with the increase in domestic oil production have contributed significantly to the current situation and outlook for the near- and mid-term future. NHTSA tentatively concluded that the world has changed, and the need of the U.S. to conserve energy, at least in the context of the CAFE program, has also changed.

Of two other factors under 32902(g), the NPRM explained that the changes were perhaps less significant. NHTSA suggested that all of the alternatives appear as though they could narrowly be considered *technologically* feasible, in that they could be achieved based on the

existence or the projected future existence of technologies that could be incorporated on future vehicles. With regard to the effect of other motor vehicle standards of the Government on fuel economy, the NPRM explained that it was similarly not heavily limiting during this rulemaking time frame. The NPRM analysis projected that neither safety standards nor Tier 3 compliance obligations appeared likely to make it significantly harder for industry to comply with more stringent CAFE standards, and that EPA's CO₂ standards should have no greater effect on difficulty in meeting CAFE standards than already existed.

For economic practicability, the NPRM considered the traditional definition used by the agency, and expressed concern that all of the alternatives considered in the proposal could raise economic practicability concerns. NHTSA stated that it believed there could be potential for unreasonable elimination of consumer choice, loss of U.S. jobs, and a number of adverse economic consequences under nearly all if not all of the regulatory alternatives considered in the NPRM. NHTSA explored consumer choice issues given a foreseeable future of relatively low fuel prices and the likelihood that more stringent CAFE standards could cause automakers to add technology to new vehicles that consumers do not want, or prevent the addition of technology to new vehicles that consumers do want, and suggested that there could be risk that such elimination of consumer choice could be unreasonable. NHTSA explained its assumption, based on repeated manufacturer input, that fuel-saving technologies that paid for themselves within 2.5 years would be added regardless of CAFE stringency, meaning that the power of CAFE standards (by themselves) to compel fuel savings was reduced. NHTSA suggested that requiring more technology to be added than consumers were willing to pay for could have dampening effects on vehicle sales, particularly given forecasted relatively low gas prices, increasing the likelihood of automaker non-compliance with more stringent standards due to difficulty in selling higher-fuel-economy models. NHTSA examined the levels of electrification necessary to meet the various regulatory alternatives evaluated in the NPRM and compared them with information about consumers' willingness to purchase vehicles with these technologies and even to spend money on fuel economy improvements generally. NHTSA suggested that if the market for higher fuel-economy vehicles exists and is already possibly saturated, increasing fuel economy requirements could create economic practicability concerns by affecting sales and consumer choice.

NHTSA recognized that automakers cross-subsidize regulation-driven cost increases and expressed concern about their ability to do that under sustained, ongoing increases over many years, and the corresponding concern that continued cross-subsidizing could create affordability problems for lower-income consumers if manufacturers pass costs forward to consumers more broadly rather than concentrating them in high-volume, higher-profit vehicles. NHTSA suggested that higher vehicle prices and monthly vehicle payments could outweigh, for at least some new vehicle purchasers, the benefit of fuel savings, because vehicle payments are fixed costs and fuel costs may be less fixed. NHTSA expressed concern that as vehicles get more expensive in response to higher CAFE standards, it will become more and more difficult for finance companies and dealers to continue creating loan terms that keep monthly payments low and do not result in consumers' still owing significant amounts of money on the vehicle by the time they can be expected to be ready for a new vehicle. This situation may imply a bubble in

new vehicle sales, the effects of which could fall disproportionately on new and low-income buyers. NHTSA suggested that these effects could impact both fleet-wide safety (by slowing fleet turnover) and consumer choice. The NPRM also expressed concern that the sales and employment analyses were unable to capture (1) the risk that manufacturers and dealers may not be able to continue keeping monthly new vehicle payments low, or (2) the risk that manufacturing could shift overseas as manufacturing costs rise.

NHTSA also examined the net benefits of the various regulatory alternatives, and noted that the analysis showed that consumers recoup only a portion of the costs associated with increasing stringency under all of the alternatives, because the fuel savings resulting from each of the alternatives was substantially less than the costs associated with the alternative, meaning that net savings for consumers improved as stringency decreased. NHTSA explained that it recognized that this was a significantly different analytical result from the 2012 rule, which showed the opposite trend, and explained that the result was different because the facts and analysis underlying the result were also different, and enumerated the noteworthy differences, such as payback assumptions; fleet composition; what levels of technologies had already been applied; the costs and effectiveness values for some of those technologies; fuel price forecasts; the value of the rebound effect; the value of the social cost of carbon; accounting for price impacts on fleet turnover; not limiting mass reduction to only the largest vehicles; and the value of a statistical life having increased. NHTSA explained that all of these changes, together, meant that the standards under any of the regulatory alternatives (compared to the preferred alternative) were more expensive and had lower benefits than if they had been calculated using the inputs and assumptions of the 2012 analysis. This assessment, in turn, contributed to the agency's decision to reevaluate what standards might be maximum feasible in the model years covered by the rulemaking. NHTSA explained that it had thus both relied on new facts and circumstances in developing the proposal and reasonably rejected prior analyses relied on in the 2012 final rule.²⁸⁵⁹

NHTSA then considered that “maximum feasible” may change over time as the agency assessed the relative importance of each factor that Congress requires it to consider, and tentatively concluded that proposing CAFE standards that hold the MY 2020 curves for passenger cars and light trucks constant through MY 2026 would be the maximum feasible standards for those fleets and would fulfill EPCA's overarching purpose of energy conservation in light of the facts before the agency and as the agency expected them to be in the rulemaking time frame. NHTSA recognized that this was a different interpretation from the 2012 final rule and explained that the context of that rulemaking was meaningfully different from the current context, because the facts had changed the importance of the need of the U.S. to conserve energy, and NHTSA recognized that under that circumstance, while more stringent standards may be possible, insofar as production-ready technology exists that the industry could physically employ to reach higher standards, it was not clear that higher standards would be economically

²⁸⁵⁹ See *FCC v. Fox Television Stations*, 556 U.S. at 514-515; see also *NAHB v. EPA*, 682 F.3d 1032 (D.C. Cir. 2012).

practicable in light of current U.S. consumer needs to conserve energy. Therefore, NHTSA stated, it viewed the determination of maximum feasible standards as a question of the appropriateness of standards given that their need—either from the societal-benefits perspective in terms of risk associated with fuel price shocks or other related catastrophes, or from the private-benefits perspective in terms of consumer willingness to purchase new vehicles with expensive technologies that may allow them to save money on future fuel purchases—seems likely to remain low for the foreseeable future. NHTSA also considered the effects of the standards on highway safety and expressed concern that because more stringent standards could depress sales and slow fleet turnover, and because higher fuel economy leads to more driving and more exposure to crash risk, all regulatory alternatives would improve safety as compared to the augural standards.

Hundreds of thousands of comments addressed stringency and, thus, the agency’s evaluation of what standards were maximum feasible. Most of those focused on the augural standards: many individual commenters supported reducing the stringency of the standards from augural levels—some citing estimates of cost, and some citing concerns about consumer choice. Many comments by other individual commenters supported retaining stringency at augural levels or increasing stringency beyond that level—generally citing concerns about climate change and increased fuel costs under less stringent standards. A few commenters, like CEI, expressly supported the proposal, and even suggested that stringency should be decreased further. Many other commenters, including environmental and consumer groups, health advocacy organizations, and a number of State organizations, argued that the proposal was flawed and/or that the augural standards should be finalized because more stringent standards help to reduce climate change and address other air quality issues.²⁸⁶⁰ The Congressional Tri-Caucus commenters supported maintaining the augural standards, stating that they contribute to employment and protect low income communities and communities of color.²⁸⁶¹

The Alliance and Global Automakers both supported final standards that increased in stringency year over year. The Alliance stated that it could support stringency increases between 0 percent per year and 2-3 percent per year “along with the inclusion of appropriate flexibilities.”²⁸⁶² Global stated that increases should be “meaningful”²⁸⁶³ and suggested that “[i]n order for the U.S. auto industry to remain competitive and continue to export vehicles to the rest of the world, industry is best served by a reasonable, steady ramp rate that accounts for investments made and the global nature of the market. Steady increases allow for long-term

planning and create an environment of security that fosters ongoing investment in vehicle technology and consumer confidence in purchasing new vehicles. It also provides a level playing field upon which automakers can compete.”²⁸⁶⁴ Toyota made similar points, and argued that while the standards set in 2012 are beyond maximum feasible today, the “statutes support an adjustment to those standards that reflect the realities of the market, consumer choice, and the pace of technological advancement acceptable to consumers.”²⁸⁶⁵ Mazda stated that it supported “increasing requirements for fuel efficiency..., if they are sensible and achievable under changing market conditions.”²⁸⁶⁶

NADA commented that it was willing to support standards that increased in stringency (i.e., more stringent than the proposal) if they were economically practicable and technologically feasible, based on the evidence before the agencies; if they ensured consumer choice and “the strongest possible rate of fleet turnover”; and if passenger car and light truck standards increased at the same rate.²⁸⁶⁷ The Alliance for Vehicle Efficiency (AVE) argued that compliance shortfalls are evidence that the current rate of stringency increase is beyond maximum feasible, and that the assumptions that enabled those rates to be chosen “are no longer feasible based on consumer adoption.”²⁸⁶⁸ AVE suggested that a rate of increase of 2.5 percent per year for both cars and trucks, retroactively imposed beginning in MY 2018, would be feasible given sufficient flexibilities.²⁸⁶⁹

NADA also stressed the importance of flexibilities as a compliance tool for meeting standards that increase faster than the proposal.²⁸⁷⁰ The Minnesota agencies supported maintaining standards at the augural levels, commenting that automakers has simply “requested additional flexibility..., not a wholesale rollback of the standards,” and suggesting that additional flexibilities would enable augural levels.²⁸⁷¹ IPI disagreed with the suggestion in the NPRM that heavy automaker reliance on credits for compliance might indicate that standards were beyond maximum feasible, arguing that automakers must be either using credits about to expire, or counting on future standards being cheaper to meet due to rising consumer demand for fuel economy, technology costs decreasing over time, and the cost-effectiveness of EPA’s EV multiplier incentive.²⁸⁷²

With regard to analysis of costs and benefits, IPI argued that the final rule needed, like the 2012 rule, to cite costs and benefit expressly in discussing balancing of statutory factors, but

with a “proper” accounting of costs and benefits. IPI claimed that in the NPRM the factors were balanced “in a way that conflicts with the...controlling statute[] and weighed...without regard for the accuracy of the accompanying cost-benefit analysis.”²⁸⁷³ IPI stated that “...the agencies’ analysis produced biased and irrational results at each of the steps in that causal chain, leading to a Proposed Rule that vastly overstates the benefits of the rollback and understates the benefits society foregoes with the rollback,” and that “[a] full and balanced analysis of all the costs and benefits that the agencies are charged with considering would reveal—as the midterm review recently confirmed—that the baseline standards will deliver massive net social benefits, and the proposed rollback is unjustified.”²⁸⁷⁴

With regard to net benefits, the States and Cities commenters stated that prior analyses had concluded that the net benefits of the augural standards were extremely high,²⁸⁷⁵ while the Alliance stated that “[t]he NERA-Trinity Assessment confirms the Agencies’ findings that Alternatives 1, 5, and 8 result in increased net benefits relative to the no-action alternative augural CAFE standards.”²⁸⁷⁶ Michalek and Whitefoot commented that “maximizing net benefits is among the most important factors to consider in policy selection because it is an effort to weigh a variety of policy implications on a common basis and seek decisions that are beneficial to society overall,” but also cautioned that estimates are inherently uncertain and should be transparent and clearly justified; that sensitivity analysis is necessary; that a net benefits analysis will not be able to capture distributional effects or changes in behavior caused by the policy; and that “it is not clear that there is necessarily any relationship between MNB and setting the ‘maximum feasible’ criteria while considering ‘economic practicability.’”²⁸⁷⁷ IPI disagreed with the NPRM’s suggestion that feasibility concerns could lead NHTSA not to maximize net benefits, stating that “if a standard were truly not feasible, then its costs would be prohibitively high, and a full and fair cost-benefit analysis would reflect that.”²⁸⁷⁸

CARB argued that “[a]lthough EPCA provides NHTSA with some discretion with respect to balancing the four factors, that discretion is nevertheless constrained by EPCA’s overriding mandate of conserving energy.”²⁸⁷⁹ CARB further stated that EPCA “envision[s] the promulgation of increasingly stringent requirements to ensure the continued reductions of both emissions and fuel consumption from motor vehicles.”²⁸⁸⁰ Michalek and Whitefoot similarly commented that the requirement that standards be maximum feasible necessarily means that stringency must increase over time, because technology capabilities and cost are constantly improving; international regulations are constantly increasing in stringency; and if standards are

held constant, automakers will always exceed them.²⁸⁸¹ The States and Cities commenters cited the CAS language from the D.C. Circuit that “[i]t is axiomatic that Congress intended energy conservation to be a long term effort that would continue through temporary improvements in energy availability,” and argued that “[w]hile NHTSA purports to acknowledge this purpose and the importance of improving fuel economy over time, NHTSA proposes to do the opposite: roll back fuel economy standards for a period of at least *six years*.”²⁸⁸² The States and Cities commenters further argued that NHTSA had “departed sharply from its past interpretations and practice without an adequate explanation, often without even an acknowledgement,” citing *Fox Television*, insofar as the 2012 final rule justification had noted that less stringent regulatory alternatives would have conserved less energy than the then-finalized standards, as compared to “[w]ith the Proposed Rollback, NHTSA has radically changed positions—assuming energy conservation provides little, if any, benefits, for example—without explaining or even acknowledging this complete reversal of course.”²⁸⁸³ The States and Cities commenters concluded that it was “impermissible” for NHTSA to balance “the factors in a manner that contravenes EPCA’s central purpose of energy conservation.”²⁸⁸⁴

ACEEE commented that NHTSA did not have discretion to assess whether the need of the U.S. to conserve energy was as great as when EPCA was first passed, arguing that “[t]he statute does not ask for a determination on whether the nation needs to save energy. It assumes the need and directs that the need be taken into account along with other considerations.”²⁸⁸⁵ Securing America’s Energy Future commented that the need of the U.S. to conserve energy continued, and that “[a]lthough the nation is undoubtedly more energy secure than it was before the start of the U.S. shale oil revolution ten years ago,”²⁸⁸⁶ “[u]ntil the U.S. transportation sector is no longer beholden to oil, the country will be vulnerable to oil price volatility. Improving the fuel efficiency of the U.S. vehicle fleet is a valuable insurance policy against this volatility.”²⁸⁸⁷ IPI also commented that fuel efficiency standards act as insurance, but against unpredictable future fuel prices.²⁸⁸⁸ IPI stated that anticipating relatively low future fuel prices was not an appropriate basis for finalizing the proposal, both because fuel costs may rise in the future, and also because EPA’s Final Determination “found that that even with the lowest prices projected in AEO 2016 of close to \$2, the ‘lifetime fuel savings significantly outweigh the increased lifetime costs’ of the GHG standards.”²⁸⁸⁹ IPI further argued that “[i]n ignoring the [FD] analysis, the Proposed Rule has failed to provide a ‘reasoned explanation’ for dismissing the ‘facts and

circumstances that underlay’ the original rule, rendering its analysis arbitrary and capricious.”²⁸⁹⁰ IPI also argued that NHTSA had not adequately explained its “shift since 2012 in its interpretation and application of the need to conserve energy factor,” stating that “[a]ctual fuel savings, and the associated benefits to consumers, the environment, and society, were at the heart of NHTSA’s analysis of the need to conserve energy factor back in 2012. Now the agency ignores those conclusions from 2012 and relies on mistaken and inconsistent interpretations of petroleum import projections and the urgency of climate change to justify ignoring this statutory factor and giving primacy instead to economic practicability and safety effects. The failure to explain this shift in approach is arbitrary.”²⁸⁹¹

UCS argued that the need of the United States to conserve energy is “the most important of the four required factors” according to *CBD v. NHTSA*, and claimed that “NHTSA has manipulated the evaluation of the factors to produce a result that supports the preferred option in the NPRM.”²⁸⁹² The States and Cities commenters argued that it was “[c]ynical...” for NHTSA to justify the proposal on the basis that “the oil intensity of U.S. GDP has continued to decline” in part as a result of increasingly stringent CAFE standards, and on the basis that “[m]anufacturers have responded to fuel economy standards and to consumer demand over the last decade to offer a wide array of fuel-efficient vehicles in different segments and with a wide array of features.”²⁸⁹³

CARB and CBD *et al.* argued that if NHTSA’s analysis indicates that automakers will voluntarily exceed the standards, then the standards cannot be maximum feasible.²⁸⁹⁴ Robertson commented relatedly that standards should not be set below augural levels because “Much higher fuel economy and reduced emissions have been achieved by several lower priced makes and models using hybrid technology.”²⁸⁹⁵ Blue Planet Foundation stated that the augural standards are feasible because automakers have already invested in technologies, and electrification is projected to continue to grow cheaper over time, so that “even the up-front cost of an EV will begin to reach parity with gas-powered cars by 2024.”²⁸⁹⁶ ACEEE also cited the voluntary overcompliance in the NPRM analysis as evidence that there could not be diminishing returns from higher fuel efficiency standards, because “the list of [cost-effective] technology [must] continually regenerate itself” if manufacturers would continue applying it in the absence of future standards. Moreover, ACEEE argued, past analyses had always found plenty of available cost-effective technologies, and automakers would find a way to apply them.²⁸⁹⁷

²⁸⁹⁷ ACEEE, NHTSA-2018-0067-12122, main comments, at 9.

Based on the information before the agencies and considering carefully the comments received, NHTSA has determined that the preferred alternative identified in the proposal—amending the MY 2021 standards to match MY 2020, and holding those standards flat through MY 2026—does not represent the maximum feasible standards, and that the maximum feasible standards for MYs 2021-2026 passenger cars and light trucks increase in stringency by 1.5 percent per year from the MY 2020 standards. EPCA/EISA grants the Secretary (by delegation, NHTSA) discretion in how to balance the relevant statutory factors, while bearing in mind EPCA’s overarching purpose of energy conservation. Many commenters cited the Ninth Circuit’s language in *CBD v. NHTSA* that “the overarching purpose of EPCA is energy conservation,”²⁸⁹⁸ and the D.C. Circuit’s language in *CAS v. NHTSA* that “[i]t is axiomatic that Congress intended energy conservation to be a long term effort that would continue through temporary improvements in energy availability.”²⁸⁹⁹ NHTSA has considered those comments and those court decisions carefully as it made the decision set forth in the final rule.

NHTSA agrees with commenters that energy conservation remains important, and that changed conditions, even significantly changed conditions, do not obviate NHTSA’s obligation to set maximum feasible CAFE standards as directed by Congress. Many commenters disagreed strongly with NHTSA’s suggestion in the NPRM that increased U.S. petroleum production, and the U.S.’s likely imminent status as a net petroleum exporter, decreased the need of the U.S. to conserve energy. NHTSA agrees that there is still a need to conserve energy, and oil in particular. Like an insurance policy or a savings account, continuing to move the needle forward on CAFE helps position Americans better to weather certain types of possible future uncertainty. NHTSA believes that it is reasonable to be somewhat conservative about this risk, and thus to set CAFE standards that increase in stringency year over year through MY 2026.

That said, NHTSA believes that there are limits to how much uncertainty the CAFE program can mitigate—continuing to make progress is important, but it is also important to be transparent and realistic about what is being accomplished, even if NHTSA were able to set standards beyond levels that NHTSA considers maximum feasible. NHTSA also continues to believe that structural changes in global oil markets over the last 10 years, driven in part by changes in demand both in the U.S. and abroad, and in part by the significant growth in U.S. petroleum production, have led to a fundamental shift in the dynamics of global oil prices, which has in turn improved U.S. (and possibly, global) energy security. NHTSA believes that this shift is important to consider as NHTSA weighs the need of the Nation to conserve energy.

NHTSA acknowledges that price shocks can still happen. The large scale attack on Saudi Arabia’s Abqaiq processing facility—the world’s largest crude oil processing and stabilization plant—on September 14, 2019 caused “the largest single-day [crude oil] price increase in the past decade,” of between \$7 and \$8, according to EIA.²⁹⁰⁰ The Abqaiq facility has a capacity to

²⁸⁹⁸ *CBD*, 508 F.3d 508, 537 (9th Cir. 2007), opinion vacated and superseded on denial of reh’g, 538 F.3d 1172 (9th Cir. 2008).

²⁸⁹⁹ *CAS*, 793 F.2d 1322, 1340 (D.C. Cir. 1986).

²⁹⁰⁰ <https://www.eia.gov/todayinenergy/detail.php?id=41413>.

process 7 million barrels per day, or about 7 percent of global crude oil production capacity. By September 17, however, also according to EIA,

Saudi Aramco reported that Abqaiq was producing 2 million barrels per day, and they expected its entire output capacity to be fully restored by the end of September. In addition, Saudi Aramco stated that crude oil exports to customers will continue by drawing on existing inventories and offering additional crude oil production from other fields. Tanker loading estimates from third-party data sources indicate that loadings at two Saudi Arabian export facilities were restored to the pre-attack levels. Likely driven by news of the expected return of the lost production capacity, both Brent and WTI crude oil prices fell on Tuesday, September 17.²⁹⁰¹

Thus, the largest single-day oil price increase in the past decade was largely resolved within a week, and assuming very roughly that average crude oil prices were \$70/barrel in September 2019 (slightly higher than actual), an increase of \$7/barrel would represent a 10 percent increase as a result of the Abqaiq attack. Contrast this with the 1973 Arab oil embargo, which lasted for months and raised prices 350 percent.²⁹⁰² Saudi Arabia could have benefited, revenue-wise, from higher prices following the Abqaiq attack, but instead moved rapidly to restore production and tap reserves to *control* the risk of resulting price increases, likely recognizing that long-term sustained price increases would reduce their ability to control global supply (and thus prices, and thus their own revenues) by relying on their lower cost of production.²⁹⁰³ Even if the NPRM discussion was perhaps overconfident about the ability of U.S. shale producers to act as “swing” supply, as some commenters suggested, it seems clear from events that the *existence* of U.S. production has a stabilizing effect on global oil prices.²⁹⁰⁴

Even though the effect of significant supply disruptions appears much lower than was the case several years ago, the analysis for this final rule (like the NPRM analysis) does, in fact, explicitly account for the possible occurrence of price shocks. The cost penalty used to represent those shocks is based on arguably outdated work—more recent studies, cited by commenters, state plainly that “[i]n recent years, the United States has become much more self-reliant in producing oil, and a newer economics literature suggests that oil demand may be more elastic and U.S. GDP may be less sensitive to world oil price shocks than was previously estimated. These developments suggest somewhat lower security costs may be associated with U.S. oil

²⁹⁰⁴ The breakdown of the OPEC+ coalition as Russia and Saudi Arabia compete for market share is further evidence supporting the premise that U.S. shale production acts as a downward lever on oil price trends.

consumption.”²⁹⁰⁵ These more recent studies concede that the fact that “the world has not seen a major oil supply disruption since 2003,” and that therefore “we have no reliable method to quantify the effects of these disruptions,”²⁹⁰⁶ but even the range of uncertainty suggests that the risk has decreased relative to prior estimates. The fact that the price shock cost estimate employed in this final rule is at least twice as large as the upper bound of the range in Brown’s new estimates, and consistently close to the upper bound of the range of his more conservative estimates means that some amount of additional risk is well accounted for in today’s analysis. In truth, that risk is likely overestimated here.

Commenters (Bordoff, SAFE, CARB, IPI) argued that increased U.S. petroleum production, which improves the stability of the global supply and reduces the probability of supply interruptions, does not reduce U.S. exposure to petroleum price shocks, which are still determined by the dynamics of the global market. By reducing the probability of supply disruptions in the global market, the U.S. does reduce its vulnerability to price shocks. However, to the extent that the vulnerability to price shocks is a function of *exposure*, commenters are correct that looming petroleum independence does not entirely insulate the U.S. economy from the consequences of global oil price shocks. Some commenters further argued that the proposed standard would leave the U.S. more exposed to oil price shocks, which would harm consumers. Basic mathematics means that a less efficient on-road fleet necessarily would spend more on fuel than a more efficient on-road fleet in the event of a sudden, unexpected, and dramatic increase in oil price. The suggestion in these comments, however, is that finalizing the augural standards would sufficiently insulate U.S. consumers from harm during such an event, while finalizing any other regulatory alternative would not.

A continuous, but slow, price increase over several years is fundamentally different from the kinds of acute price shocks over which commenters have expressed understandable concern. Long-term price increases signal consumers to make investments in fuel economy, in both the new and used vehicle markets, and to diversify the vehicles in their household fleets. In a side analysis using outputs from the CAFE Model, the agencies examined the consequences of a gasoline price spike in 2030—increasing the price from \$3.40/gallon to \$6/gallon for eight months, then reverting back to \$3.40/gallon. By choosing a year so far in the future, we consider a larger gap in fleet fuel efficiency than is attributable to this action. If the agencies increase stringency again after MY 2026, the efficiency gap between the on-road fleet in the final standards and baseline would be smaller than simulated here. The analysis showed that even a nearly doubling of the fuel price, sustained for more than half a year, would result in less than one percent savings in fuel expenditures for that year under the final standards (relative to the proposal), compared to about 5 percent reduction in expenditures under the augural standards. This demonstrates that even though finalizing the augural standards would mitigate American drivers’ increase in fuel expenditures by more than the standards we are finalizing today, it

²⁹⁰⁵ Brown, Stephen, “New estimates of the security costs of U.S. oil consumption,” Energy Policy 113 (2018) 171-192, at 171. Cited in Securing America’s Energy Future, NHTSA-2018-0067-12172, at 29.

²⁹⁰⁶ Brown, at 181.

would only do so by a few percent. And as discussed below, NHTSA believes the augural standards are beyond maximum feasible at this time.

Some commenters raised the possibility that the U.S. might ban fracking at some point in the future, and suggested that therefore the need of the U.S. to conserve energy could not be assumed away. NHTSA acknowledges that the future is uncertain. Without the supply of U.S. oil in the global market, NHTSA agrees that it is foreseeable that conditions could revert somewhat to how global oil market conditions were before the ramp-up in U.S. supply—i.e., that the global market as a whole could be somewhat less stable and thus fuel prices could be somewhat more prone to increase unexpectedly and for longer periods. Pulling out of the market on the supply side means that we would lose the ability to influence the market on that side. Presumably, part of the policy objective of banning fracking would be to accelerate a transition to a post-oil transportation system. In that scenario, presumably decision-makers would consider higher oil prices an acceptable tradeoff for less driving and lower emissions. That said, the availability of shale oil production capacity does exist today, and is not realistically in question. And, even if the future availability of that capacity was realistically doubtful, any increase in fuel economy above current levels, like the final rule will require, will help somewhat to mitigate the economic pain to drivers of that event were it to occur, as shown above.

As noted above, Securing America's Energy Future commented that "[a]lthough the nation is undoubtedly more energy secure than it was before the start of the U.S. shale oil revolution ten years ago,"²⁹⁰⁷ "[u]ntil the U.S. transportation sector is no longer beholden to oil, the country will be vulnerable to oil price volatility. Improving the fuel efficiency of the U.S. vehicle fleet is a valuable insurance policy against this volatility."²⁹⁰⁸ (Emphasis added.) NHTSA agrees fully with this comment. Energy security concerns were the driving force behind the creation of the CAFE program, as discussed in the NPRM. U.S. energy security has improved, but the only way to resolve petroleum-related energy security concerns entirely would be for the U.S. vehicle fleet to stop using oil. And doing so would not avoid energy-related concerns entirely, but rather shift them away from petroleum (and the Middle East) and toward battery-related security (and lithium-, nickel-, cobalt-, and other metals-producing countries).²⁹⁰⁹

²⁹⁰⁷ Securing America's Energy Future, NHTSA-2018-0067-12172, at 17.

²⁹⁰⁸ *Id.*, at 7, 8.

²⁹⁰⁹ While progress is being made on developing and improving domestic sources for many of the minerals necessary for battery development, the U.S. is still heavily dependent on imports of both raw materials and batteries. Regarding minerals production and import dependence, *see* Schulz, K.J., DeYoung, J.H., Jr., Seal, R.R., II, and Bradley, D.C., eds., *Critical mineral resources of the United States – Economic and environmental geology and prospects for future supply*: U.S. Geological Survey Professional Paper 1802 (*see particularly* Chapter K, p. K1-K21 on lithium), available at https://www.commerce.gov/sites/default/files/2020-01/Critical_Minerals_Strategy_Final.pdf and <https://pubs.usgs.gov/pp/1802/k/pp1802k.pdf>. Regarding vehicle battery supply chains, *see* Coffin, D., and J. Horowitz, "The Supply Chain for Electric Vehicle Batteries," *Journal of International Commerce and Economics*, December 2018, available at https://www.usitc.gov/publications/332/journals/the_supply_chain_for_electric_vehicle_batteries.pdf.

*** EO 12866 Review – Draft – Do Not Cite, Quote or Release During Review ***

NHTSA does not interpret EPCA/EISA to mean that Congress expected the CAFE program to take the U.S. auto fleet off of oil entirely—indeed, EISA renders doing so impossible because it amended EPCA to prohibit NHTSA from considering the fuel economy of dedicated alternative fuel vehicles, including electric vehicles, when setting maximum feasible standards. This means that standards cannot be set that assume their increased usage for compliance. Reading that prohibition together with the obligation to set maximum feasible standards by considering (which is hard to do without balancing) factors like economic practicability with the need of the U.S. to conserve energy, NHTSA believes that Congress intended CAFE to try to mitigate the risk of gas lines, but not to shift the fleet entirely off of oil. Moreover, the EISA-added requirement that standards “increase ratably” for MYs through 2020 ceases to apply beginning in MY 2021. While NHTSA unquestionably has discretion to determine that standards should continue to increase post-MY 2020, NHTSA does not interpret EPCA/EISA as *requiring* that they do, as long as they are maximum feasible. Several commenters suggested that standards that do not continue to increase, by definition, cannot be maximum feasible, but NHTSA believes that this interpretation does not account for the clear requirement that maximum feasible standards be determined with reference to the four statutory factors. The statute does not preclude an interpretation that non-increasing standards could be maximum feasible, depending on the facts before the agency. Neither does the statute preclude an interpretation that amending standards downward can be maximum feasible, as has occurred in the past in response to changes in consumer demand.²⁹¹⁰

Nevertheless, for purposes of this final rule, NHTSA does believe that standards that increase in stringency are maximum feasible; the question remains by how much those standards should increase. While NHTSA agrees that CAFE standards must conserve energy, the improvement in energy security discussed above is entirely relevant to *how much energy should be conserved*. If the marginal improvement in energy security of increasing CAFE stringency from one regulatory alternative to another is very small, as it appears to be based on the above discussion, then other aspects of the need of the U.S. to conserve energy must be considered next to see what effect they have.

Consumer costs, as discussed above, is another aspect of the need of the U.S. to conserve energy. The final rule analysis estimates that all alternatives besides the baseline/augural standards would result in higher fuel costs for consumers, as follows:

Table VIII-2 - Estimated Average Fuel Costs Over the Useful Lives of MY 2029 Vehicles, Under Each Regulatory Alternative

Scenario Name	Lifetime Fuel Expenditures (2018 \$)*		Lifetime Increase (2018 \$)*	
	7% discount rate	3% discount rate	7% discount rate	3% discount rate
Augural Cafe Standards	13,525	17,300	-	-

*Rounded to nearest \$25

A number of commenters stated that the 2012 rulemaking had relied on fuel savings as part of its justification, and argued that the NPRM had not adequately grappled with the fact that the proposal would have cost consumers more in fuel expenditures than if NHTSA finalized the augural standards. In fact, NHTSA explained in the NPRM that while fuel costs would be higher, NHTSA believed that the higher upfront (and ongoing, if financed) costs of new vehicles and associated taxes and registration fees—as well as the opportunity cost associated with those upfront costs—would outweigh, for many consumers, the additional fuel costs that would be incurred if standards were less stringent than augural. That continues to be the case under the final rule analysis, as discussed below. In addition, Section VI.B.1.d.xii discusses how past rulemaking analyses assumed that consumers were ‘myopic’ and/or did not have adequate information about the benefits of fuel savings, which led them to choose to purchase less efficient vehicles than they otherwise would if they better understood the costs or savings they would accrue. As Section VI.B.1.d.xii explains, the agencies are less certain today that consumers improperly value fuel savings. Vehicle buyers today have more information about fuel costs than ever before, including right on the window sticker when considering a new vehicle purchase, and it is ultimately a private choice whether consumers prefer improvements in other vehicle attributes over additional fuel economy. When fuel costs are expected to rise manageably over time, it may be that consumers are comfortable choosing to absorb an additional \$1,350 over the vehicle’s lifetime, the estimated difference in lifetime expenditures between the proposal and if NHTSA was choosing to finalize the augural standards, and are even more comfortable choosing to absorb an additional \$1,125, the estimated difference in lifetime expenditures between the final standards and what the augural standards would have required. If fuel prices rise less than anticipated, as they have done since the 2012 final rule, buyers face an even smaller tradeoff between foregone fuel savings and the value of improvements in other aspects of new cars.

Every analysis of CAFE/CO₂ standards relies on hundreds of assumptions, and estimates of costs and benefits developed as part of those analyses, by their very nature, depend on those assumptions. Specifically, the net benefits associated with each alternative result from the assumptions used and the relationships between vehicle production, ownership, and usage in

which the assumptions interact. Put more simply, inputs affect outputs. As discussed in the section above on economic practicability, net benefits may be a consideration in the determination of maximum feasible standards, among the many other things the agency considers. While some commenters have asserted that the analysis for this rulemaking has “put a thumb on the scale by undervaluing the benefits and overvaluing the costs of more stringent standards,”²⁹¹¹ this final rule has identified a number of critical assumptions in the 2012 final rule that were problematic in the other direction (i.e., undervaluing the costs and overvaluing the benefits), for a variety of reasons. For example, the projected fuel prices in that analysis inflated the value of fuel savings relative to what has actually occurred. That assumption about projected fuel prices was solidly grounded at the time, but is no longer so, and continuing to use it would not be reasonable, even if the consequence is that the benefits of the all of the regulatory alternatives decrease as compared to what the 2012 analysis showed. Additionally, the assumption in 2012 that no market exists for fuel economy improvements at any fuel price or technology cost artificially inflated the value of fuel savings attributable to the standards in each regulatory alternative. The combination of assumptions and relationships (the examples above, and others) in the 2012 final rule produced estimates of net benefits that continued to increase with stringency from 1 percent per year through 6 percent per year.²⁹¹² Under some alternatives, benefits actually would have appeared to be infinite, growing faster than the discount rate, if the analysis had been extended far enough into the future. No market works this way, and there is no reasonable set of assumptions under which costs could *never* exceed benefits no matter how much technology was deployed or how much stringency was required. Rather than demonstrating meaningfully that more stringent standards are always more beneficial to society, the result from the 2012 analysis suggests that that analysis was critically flawed. That said, while the 2012 analysis appeared to show that more technology, at a faster pace, is always preferable from the perspective of net benefits, the agencies ultimately relied on other features of the analysis and considerations of impacts in choosing a preferred alternative. While today’s analysis produces an inflection point – a level of stringency where further increases reduce net benefits as the tradeoff between regulatory costs and resulting net benefits tips the other way – the agencies similarly rely on considerations beyond net benefits in choosing the preferred alternative.²⁹¹³

NHTSA also agrees with many commenters that environmental (both climate and air quality) concerns are relevant to the need of the U.S. to conserve oil, as explained above. As the Supreme Court stated in *Massachusetts v. EPA*, “[a] reduction in domestic emissions would slow the pace of global emissions increases,”²⁹¹⁴ and there is no question that CAFE standards directly affect CO₂ emissions. Besides providing information on differences between the regulatory

²⁹¹¹ See *CBD v. NHTSA*, 538 F.3d 1172, 1189 (9th Cir. 2008).

²⁹¹² The 7 percent per year alternative happened to be indistinguishable from the 6 percent alternative in that analysis.

²⁹¹³ See *CBD v. NHTSA*, 538 F.3d 1172, 1188 (9th Cir. 2008).

²⁹¹⁴ *Mass. v. EPA*, 549 U.S. at 526.

alternatives in terms of million metric tons, the NPRM also provided a chart illustrating the difference between the estimated atmospheric CO₂ concentration (789.76 ppm) in 2100 under the proposal as compared to the estimated level under the augural standards (789.11 ppm) in a scenario where no CO₂ emissions reduction measures are implemented throughout the planet.²⁹¹⁵ The NPRM noted that this translated to 3/1000ths of a degree Celsius increase in global average temperatures by 2100, relative to the augural standards. Many commenters strongly objected to the framing of these findings, as discussed above in the section on the environmental implications of the need of the U.S. to conserve energy. NHTSA does not believe that changing the framing changes the agency's findings.²⁹¹⁶ For this final rule, the Preferred Alternative would result in 922.5 million metric tons of CO₂ more than the estimated emissions if the augural standards were to be finalized (for MY 2017 – MY 2029 vehicles), which is 160.2 million fewer tons than if the proposed Preferred Alternative were to be finalized. It is reasonable to consider these raw million-metric-ton estimates in terms of their effects, namely, on estimated temperature change and sea level rise, which are the primary climate effects referred to and estimated. The FEIS accompanying today's rule estimates that, by 2100, global mean surface temperature will increase by 3.487 degrees (Celsius) under either the proposed or final standards, versus 3.484 degrees under the augural standards. The FEIS shows corresponding sea level rise in 2101 reaching 76.34 cm under the final standards, 76.35 cm under the proposed standards, and 76.28 cm under the augural standards. This is accounted for in economic terms (i.e., translated from fractions of a degree temperature rise and from millimeters of sea level rise, among other things, into dollar-based effects) in the measure of the social cost of carbon, described in Section VI.D.1.b.iii, and is discussed both quantitatively and qualitatively in the FEIS.

NHTSA is mindful of the language in *Massachusetts v. EPA* that “[a]gencies ... do not generally resolve massive problems in one fell regulatory swoop,”²⁹¹⁷ and acknowledges the concerns of many commenters that standards less stringent than augural may result in higher CO₂ emissions. In response, it is important to remember that even under the proposal, sales of new vehicles would, over time, have continued to improve the fuel economy and reduce the CO₂ emissions of the on-road fleet through fleet turnover effects, as discussed in Section IV. Under the final rule, those rates of improvement will likely be faster than they would have been if NHTSA were finalizing the proposal. Emissions are still being reduced under the final rule, and the on-road fleet will be less energy and carbon intensive than it is today. NHTSA is taking the

²⁹¹⁵ 83 FR at 42996-97 (Aug. 24, 2018).

²⁹¹⁶ In fact, NHTSA's analysis in Section 8.6.4.2 of the FEIS illustrates that the differences between alternatives are similar in reference to other GCAM scenarios. Regardless of whether there will be widespread global efforts to mitigate climate change, the impacts of this action are roughly the same.

²⁹¹⁷ *Mass. v. EPA*, 549 U.S. at 524.

impacts of CO₂ emissions into account, while also considering the other statutory factors in its balancing.

It is also important to note that the science of climate change and the models used to assess effects on climate variables (and other effects discussed in Section VII.A.4.g, and in the DEIS/FEIS) are subject to various types of uncertainty. In light of this, NHTSA also conducted climate sensitivity analyses in the FEIS.²⁹¹⁸ In these analyses, NHTSA considered a range of climate sensitivities (1.5°C, 2.0°C, 2.5°C, 3.0°C, 4.5°C, and 6.0°C) for a doubling of CO₂ compared to preindustrial atmospheric concentrations (278 ppm CO₂). Even under the least stringent alternative considered (the proposal) and assuming the highest level of climate sensitivity (6.0°C), the global mean surface temperature increase in 2100 was 0.006°C higher than under the augural standards. Thus, accounting for some of this uncertainty, impacts on global mean surface temperature resulting from this action remain very small.

This final rule does not directly involve the regulation of pollutants such as carbon monoxide, smog-forming pollutants (nitrogen oxides and unburned hydrocarbons), or “air toxics” (e.g., formaldehyde, acetaldehyde, benzene). Nevertheless, NHTSA recognizes that this rule is expected to impact such emissions indirectly (by reducing travel demand and accelerating fleet turnover to newer and cleaner vehicles on one hand while, on the other, increasing activity at refineries and in the fuel distribution system). Based on a review of Section VII.A.4.c. above and the FEIS, NHTSA believes these impacts are much smaller than impacts on fuel use and CO₂ emissions, and therefore factor in less to the need of the U.S. to conserve energy.²⁹¹⁹

For criteria pollutants, NHTSA estimates that emissions over the lifetimes of vehicles through MY 2029 under the alternatives will not change significantly. Tailpipe emissions of most pollutants will generally decrease, while upstream emissions will generally increase. Overall emissions under the action alternatives for most pollutants will increase over time. Changes are not uniform year-to-year, however, reflecting the complex interaction of the amount of highway travel, the distribution of that travel among different vehicles, upstream processes, etc. Generally, tailpipe air toxic emissions decrease while upstream air toxic emissions increase. Over the long term, however, the upstream emissions increase further while the decreases in tailpipe emissions become less pronounced. Overall, NHTSA anticipates that air toxic emission will increase over time under the action alternatives. Most alternatives result in cumulative increases in adverse health impacts associated with total upstream and tailpipe pollutant emissions. Although some alternatives would have resulted in decreases, the differences among alternatives across the lifetime of vehicles through MY 2029 are not large.

²⁹¹⁸ See Sections 5.4.2.3 and 8.6.4.2 of the FEIS.

²⁹¹⁹ For an explanation of how NHTSA considers environmental impacts and the differences between the preamble and FEIS analyses, see Section VII.A.4.c.1 above.

NHTSA also considered the various impacts reported qualitatively in the FEIS and described briefly above in Section VIII.B.3. Although the agency cannot compare the impacts of the alternatives quantitatively (except to the degree that they are otherwise covered by the agency's monetary cost-benefit analysis, such as through the social cost of carbon), NHTSA recognizes that such impacts would generally increase under all the action alternatives compared to the augural standards. In Chapter 8 of the FEIS, for example, NHTSA provides a qualitative discussion of the long-term impacts of climate change on key natural and human resources. While these impacts would be expected to increase under the action alternatives, the change is expected to be very small. In contrast, the FEIS also discusses some environmental impacts that would decrease with the lower stringencies considered in this rulemaking. For example, in Chapter 6 of the FEIS, NHTSA provides a literature review of potential lifecycle impacts as a result of manufacturer use of various materials and technologies to meet the standards. NHTSA can account for the benefits to tailpipe emissions of these technologies as part of its evaluation of technology effectiveness. However, as discussed in the FEIS, accounting for the upstream emissions associated with the processes used in the manufacture of these technologies can be complicated. Because the adoption of these materials and technologies would vary across alternatives, and each has varying upstream impacts, the agency cannot provide meaningful comparisons across alternatives. Still, any benefit to tailpipe CO₂, criteria pollutant, or air toxic emissions of more stringent alternatives would be offset by the increased upstream impacts reported in that section.²⁹²⁰

In total, environmental impacts factor into the need of the U.S. to conserve energy, but those impacts cannot be considered in isolation. While some impacts are more significant than others, NHTSA must consider how much weight to place on this factor as well as the relative weight of other factors.

Thus, even if the agency no longer interprets the need of the U.S. to conserve energy as necessarily boundless as it once did, as it explained in the NPRM and again in the discussion above, NHTSA continues to believe that the factor functions in the overall balancing to push toward increases in stringency, and notes that any increase in stringency over the last binding standards—not in question at this point, the standards for MY 2020—does conserve energy and reduce negative environmental impacts. In fact, fleet turnover over time means that less energy is being consumed by the fleet over time even if standards did *not* increase year over year. Even if new vehicles are not all as efficient as would have been required under more stringent standards, they are still more efficient on average than the older vehicles they are replacing,

²⁹²⁰ In most cases, tailpipe emissions benefits offset upstream environmental impacts associated with materials and technologies NHTSA considered in its analysis. However, in some cases, results may not align with conventional wisdom. For example, while EVs can offer significant life-cycle GHG emissions savings over conventional vehicles, this is highly dependent on the time and location of charging. In some regions, life-cycle impacts are similar for EVs and conventional vehicles.

particularly after a decade of successive increases in CAFE standard stringency, as Section IV above discusses. The on-road fleet has well over 250 million vehicles, dwarfing the roughly 16 million new vehicles sold each year. Comprehensive energy savings come from turning over legacy vehicles in the fleet so that overall fleet fuel economy increases. If the NPRM's preferred alternative were finalized, the fuel consumption of the passenger car and light truck fleet would have fallen from roughly 8.5 million barrels per day to roughly 7 million barrels per day by 2050 as the fleet turned over. Finalizing the 1.5 percent alternative reduces that number to 6.3 million barrels per day. That breaks the trend of increasing oil consumption over time, and conserves energy.

Looking at the other statutory factors, as discussed above in Section VIII.B.1.e, NHTSA continues to believe that technological feasibility is not inherently limiting in the timeframe covered by this rulemaking, and that all technologies reasonably applicable during the rulemaking timeframe have been considered as part of the analysis. Section VIII.B.1.e also discussed the effect of other motor vehicle standards of the Government on fuel economy. NHTSA has either accounted for the effects of such standards in its analysis, or (for certain standards that some commenters would urge the agency to consider) is not required to do so. The effect of other motor vehicle standards of the Government on fuel economy thus, also, does not drive the agency's decision in today's final rule.

Economic practicability remains a complex factor to consider and balance, as discussed above, encompassing a variety of different issues that are each captured to various degrees through the analysis. Estimated impacts on per-vehicle cost are one issue; estimated sales and employment impacts are issues; uncertainty surrounding future market conditions and consumer demand for fuel economy (versus consumer demand for other vehicle attributes) are other issues. Consumers may respond to per-vehicle cost increases by choosing to keep their current vehicle or buy used vehicles instead of new vehicles, with consequent effects on new vehicle sales and the overall fleet makeup; consumers may respond to new fuel-economy-improving technologies on certain models by choosing to buy other models, especially when fuel costs are not expected to increase significantly in the ownership timeframe and consumers value other vehicle attributes more than they value fuel economy. Either of these responses may cause manufacturers both to lose money and to face further difficulties in meeting the CAFE standards. While there are significant benefits for both manufacturers and consumers under attribute-based standards, manufacturers must still sell enough "target-beaters" to balance out sales of less-fuel-efficient vehicles and meet their overall fleet-average compliance obligations. If consumer demand shifts strongly away from target-beaters, CAFE compliance will be a struggle, even if the target-beaters are widely available. Section IV above discusses this phenomenon in more detail. And if consumers buy fewer new vehicles in response to per-vehicle cost increases, the fleet as a whole will turn over more slowly, and fuel conservation gains may also be slowed. NHTSA does not believe that that is EPCA's goal. Manufacturers struggling to sell new vehicles will have less capital to devote to further technological improvements; may choose to move manufacturing jobs outside the U.S. to places with lower labor costs; and so forth. A net benefits analysis may be informative to attempting to quantify some of the issues described above, but

not all of these issues lend themselves to clear quantification. The following discussion will evaluate what we believe we have reasonably been able to account for.

Per-vehicle cost estimates are relevant to NHTSA’s consideration of economic practicability because, when cost increases associated with more stringent standards are passed through to consumers as price increases, they affect consumers’ willingness and ability to purchase new vehicles, and thus influence vehicle sales and fleet turnover. A similar effect occurs in reverse when stringency is decreased.

[Table VIII-3](#)~~Table VIII-2~~ below shows the estimated effects on per-vehicle costs by regulatory alternative in MY 2029:

Table VIII-3 - Average Regulatory Costs (beyond MY 2017) in MY 2029

Scenario Name	Passenger Cars	Light Trucks	Combined
Augural CAFE Standards	2,325	3,275	2,775
0.00%/Y Pc And 0.00%/Y Lt During 2021-2026	1,350	1,425	1,375
0.50%/Y Pc And 0.50%/Y Lt During 2021-2026	1,375	1,450	1,400
1.50%/Y Pc And 1.50%/Y Lt During 2021-2026	1,475	1,825	1,650
1.00%/Y Pc And 2.00%/Y Lt During 2021-2026	1,450	1,950	1,675
1.00%/Y Pc And 2.00%/Y Lt During 2022-2026	1,600	2,300	1,925
2.00%/Y Pc And 3.00%/Y Lt During 2021-2026	1,650	2,400	2,000
2.00%/Y Pc And 3.00%/Y Lt During 2022-2026	1,775	2,750	2,225

*Rounded to nearest \$25

Generally speaking, per-vehicle costs increase as stringency increases. The agencies estimate that, by MY 2029, costs for additional fuel-saving technology (beyond that present on vehicles in MY 2017) would average about \$2,800 under the augural CAFE standards, as compared to about \$1,400 under the proposed CAFE standards, and about \$1,650 under the final CAFE standards for MYs 2021-2026. Similarly, the agencies estimate that, by MY 2029, costs for additional fuel-saving technology (beyond that present on vehicles in MY 2017) would average about \$2,600 under the augural CO₂ standards, as compared to about \$1,300 under the proposed CO₂ standards, and about \$1,600 under the final CO₂ standards for MYs 2021-2026.

Per-vehicle cost and fuel economy both affect sales estimates in the final rule analysis.

2030	16,353,639	366,774	360,008	296,225	287,777	225,528	210,734	148,850
Total	228,176,995	3,579,671	3,503,652	3,040,338	2,967,978	2,275,973	2,219,481	1,609,746

The final rule analysis indicates that industry sales decrease as stringency increases, and increase as stringency decreases. While sales under both the proposal and the final rule are comparable, each represents about a 1.5 percent reduction in total sales over the period from 2017 – 2030. In the context of 16-17 million new vehicle sales annually, NHTSA does not believe that the sales volume effects here, while significant, are necessarily determinative for economic practicability, even after accounting for fuel economy effects in the sales analysis as some commenters recommended. That said, NHTSA recognizes that the final rule sales analysis does not account for a number of factors that could cause differences between alternatives to result in changes in new vehicle sales (perhaps greater). For example, NHTSA remains concerned that significant increases in fixed upfront prices (which for many people translate to monthly financing costs) are harder for certain segments of new vehicle buyers to manage than fuel costs, which can be managed to some extent through vehicle switching or travel decisions. The sales analysis for this final rule indicates that more stringent standards tend to result in higher light truck sales and lower passenger car sales. While NHTSA does not have specific information (or a vehicle choice model) to inform the agency about which consumers (by income) buy which vehicles, and while NHTSA acknowledges that it does not account for price cross-subsidization by manufacturers to keep “entry-level” new vehicle (often, passenger car) prices low, NHTSA continues to be concerned about the possibility of a bubble in the market for new vehicles. As the Wall Street Journal reported in November 2019, “Some 33% of people who traded in cars to buy new ones in the first nine months of 2019 had negative equity, compared with 28% five years ago and 19% a decade ago, according to car-shopping site Edmunds.... Rising car prices have exacerbated an affordability gap that is increasingly getting filled with auto debt.”²⁹²¹ The sales analysis for this final rule does not directly account for these effects, but NHTSA is concerned that they may be considerable.

The sales analysis for this final rule also does not account for the potential consumer acceptance issue of more stringent standards effectively requiring the application of technologies not yet ready for widespread deployment. As widely noted, the 2012 rule assumed extremely high penetration of dual-clutch transmissions in response to standards. While the agencies stated throughout that final rule that the analysis was not meant to represent the expected response to the standards, Ford did apply DCTs to a number of vehicle models in its fleet, that resulted in major customer satisfaction issues and ultimately caused extensive buyback campaigns, customer service programs, and class-action litigation.²⁹²² Sales can be impacted as a result of standards if technologies applied in response to those standards have operational, maintenance, or customer acceptance problems, or if consumers are unwilling to pay for it. Manufacturer capital to develop and add new technologies and manage these rollout issues is finite, as discussed. Insufficient capital can also cause quality problems. The cost effects modeled in this final rule analysis, that drive the sales and scrappage analyses, only include technology costs and

²⁹²¹ AnnaMaria Andriotis and Ben Eisen, “A \$45,000 Loan for a \$27,000 Ride: More Borrowers are Going Underwater on Car Loans,” Wall Street Journal, November 9, 2019.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

RPE—they do not include the cost of stranded capital or lost consumer surplus, which are things that could drive up costs, drive down benefits, and therefore impact sales and scrappage beyond what today’s analysis shows.

As Section IV above notes, a great deal of fuel economy-improving technology has already been added to the fleet since 2012, which means that the amount of fuel economy-improving technology left to be added in response to higher standards is less than it was assumed to be in 2012. Looking at the technology penetration rates modeled in today’s analysis, it appears that the augural standards are projected to require nearly 20 percent total electrification in MY 2029, while the proposal would have required nearly 7 percent and the final standards would require nearly 8 percent. Table [xx] below shows projected electrification rates by 2029 for the regulatory alternatives—electrification refers to all models with strong hybrids, PHEVs, or full EVs:

Table VIII-5 - Electrification Rates by Alternative

Scenario Name	Strong Hybrid	Plug-In Hybrid	BEV	Total
Augural Cafe Standards	12.4%	6.5%	0.6%	19.6%
0.00%/Y Pc And 0.00%/Y Lt During 2021-2026	4.4%	1.8%	0.7%	6.9%
0.50%/Y Pc And 0.50%/Y Lt During 2021-2026	4.4%	1.9%	0.7%	6.9%
1.50%/Y Pc And 1.50%/Y Lt During 2021-2026	5.3%	1.9%	0.7%	7.9%
1.00%/Y Pc And 2.00%/Y Lt During 2021-2026	5.0%	1.9%	0.7%	7.6%
1.00%/Y Pc And 2.00%/Y Lt During 2022-2026	7.0%	2.4%	0.7%	10.0%
2.00%/Y Pc And 3.00%/Y Lt During 2021-2026	6.7%	2.5%	0.7%	9.9%
2.00%/Y Pc And 3.00%/Y Lt During 2022-2026	8.0%	3.4%	0.7%	12.1%

As the table shows, the analysis projects that meeting the augural standards could require over twice as much electrification as the final rule standards could require.²⁹²³ The current market penetration for all such vehicles is approximately 4 percent, and one can hardly argue that the technology is nascent, with hybrids having been first introduced with the Honda Insight in 1999 and Toyota Prius in 2000, plug in hybrids with the Chevrolet Volt in late-2010 and electric vehicles with the Tesla Roadster in 2008 and Nissan Leaf in late 2010. As Mr. Kreucher commented, consumers appear to be driven by fuel price. Given anticipated fuel prices during

²⁹²³ While NHTSA is prohibited by statute from considering battery electric vehicles as a compliance mechanism, we are aware that many OEMs will likely opt to produce a smaller number of fully electric vehicles rather than a large number of strong hybrid models.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

this timeframe and evidence in the market today of cannibalization within these vehicle segments (not to mention the continued phasing out of government incentives for these vehicles),²⁹²⁴ NHTSA is concerned that there could be consumer acceptance problems under more stringent alternatives, which could have sales impacts.

The final rule analysis also looked at employment effects under the different regulatory alternatives. A number of commenters argued that more stringent standards improved employment opportunities, as shown in the NPRM analysis and in other analyses, due to the need for workers to manufacture the additional technology needed to meet those more stringent standards. Similar to the NPRM analysis, the agencies' updated analysis shows labor utilization, on balance, increasing slightly with stringency, as this effect outweighs the opposing effect of changes in vehicle sales. ~~Table VIII-6~~~~Table VIII-5~~ below shows the estimated effects on U.S. auto industry employment by regulatory alternative in MY 2029:

Table VIII-6 - Estimated Industry Labor Utilization in 2029

Scenario Name	Person Years
Augural Cafe Standards	1,203,232
0.00%/Y Pc And 0.00%/Y Lt During 2021-2026	1,185,903
0.50%/Y Pc And 0.50%/Y Lt During 2021-2026	1,185,778
1.50%/Y Pc And 1.50%/Y Lt During 2021-2026	1,189,758
1.00%/Y Pc And 2.00%/Y Lt During 2021-2026	1,190,486
1.00%/Y Pc And 2.00%/Y Lt During 2022-2026	1,194,963
2.00%/Y Pc And 3.00%/Y Lt During 2021-2026	1,196,318
2.00%/Y Pc And 3.00%/Y Lt During 2022-2026	1,199,720

²⁹²⁴ 26 U.S.C. Section 30D provides for tax credits ranging from \$2,500 to \$7,500 for purchasers of qualifying plug-in hybrid (PHEV) and battery electric (BEV) vehicles, with a phaseout applying to vehicle manufactured by an automaker once they sell 200,000 qualifying vehicles. Both Tesla and General Motors have reached this threshold and the tax credit applicable to purchasers of new PHEV and BEV vehicles from those manufacturers has been reduced gradually and will phase out completely on January 1, 2020 for Tesla, and April 1, 2020 for General Motors.

The California Clean Vehicle Rebate Project was launched in 2010 to provide incentives of up to \$5,000 for purchasers or lessees of qualifying PHEV, BEV, and certain other alternative fuel vehicles. Since then, the program has undergone significant changes, including the addition of income eligibility criteria for certain incentives, and excluding eligibility toward the purchase or lease of a vehicle with an MSRP exceeding \$60,000.

Seperately, in 2005, California passed a law allowing hybrid electric vehicle (HEV), plug in hybrid electric vehicle (PHEV), and battery electric vehicle (BEV), and other qualifying alternative fuel vehicle owners to apply for a sticker allowing single-occupant access to High Occupancy Vehicle (HOV) lanes. HEV access was phased out in 2011, with elibility being limited to PHEV, BEV and other qualifying alternative fuel vehicle owners. Access is now limited to a four-year period, and only to individuals who do not receive a rebate under the California Clean Vehicle Rebate Project (unless meeting income eligibility requirements).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

It is important to note, however, that the reduction in person-years described in this table merely reflects the fact that, when compared to the standards set in 2012, fewer jobs will be specifically created to meet infeasible regulatory requirements. It is also important to note that the \$15 billion in avoided required technology costs (in MY 2029) can be invested by manufacturers into other areas, or passed on to consumers. Moreover, consumers can either take those cost savings in the form of a reduced vehicle price, or used toward the purchase of specific automotive features that they desire (potentially including a more-efficient vehicle), which would increase employment among suppliers and manufacturers.

Generally speaking, the agencies' analysis shows net labor utilization increasing with stringency, because the additional labor utilization involved with producing additional fuel-saving technology outweighs the foregone labor utilization involved with the foregone sales. As indicated above, for the scope of labor utilization accounted for in today's analysis, the agencies show about 1.20 million person-years under the augural CAFE standards and about 1.19 million person-years under either the proposed or final standards. As for sales, it is arguably instructive to consider these estimates in the broader context of U.S. employment. BLS data indicates that roughly 129 million people in the U.S. are employed full-time at the time of writing,²⁹²⁵ and that roughly 1.4 million people were employed in motor vehicle and motor vehicle equipment manufacturing in 2018.²⁹²⁶ The agencies estimate that, compared to the augural standards, the final standards will reduce automotive labor utilization associated with production of the MY 2029 fleet by about 1.1%, a slightly smaller reduction than the 1.4% estimated to occur under the proposed standards. For comparison, the Synapse Report cited often by commenters concluded that vehicle standards result in "nationwide employment increases of more than 100,000 in 2025 and more than 250,000 in 2035...these increases represent less than 0.2 percent of current U.S. employment levels."²⁹²⁷ Even at these levels, which NHTSA does not necessarily agree are accurate, the employment effects of standards are in the range of the average of more than 216,000 jobs added to the U.S. economy *during each month* of 2018.²⁹²⁸ That said, as for sales, NHTSA recognizes that the final rule labor utilization analysis does not account for a number of factors that could cause differences between alternatives to be different (perhaps greater), as discussed further below.

As discussed above, NHTSA's consideration of consumer demand as relevant to economic practicability has been upheld by the D.C. Circuit in *Center for Auto Safety v. NHTSA*. A number of commenters argued that consumers do, in fact, demand more fuel economy than the NPRM analysis assumed; that consumers will appreciate more widespread application of fuel

²⁹²⁵ <https://www.bls.gov/cps/cpsaat08.htm>.

²⁹²⁷ <https://www.synapse-energy.com/sites/default/files/Cleaner-Cars-and%20Job-Creation-17-072.pdf>, at ES-2.

²⁹²⁸ Payroll employment increased by 2.6 million jobs in 2018, an average of 216,667 per month. "The Employment Situation – December 2018," Bureau of Labor Statistics, available at: https://www.bls.gov/news.release/archives/empst_01042019.pdf.

economy-improving technologies that NHTSA appears to believe they will tolerate; that NHTSA was wrong to assume that fuel prices will remain relatively low in the future and continue to dampen consumer demand for fuel economy; and that vehicle manufacturers will not make tradeoffs between investments in fuel economy improvements and investments in other vehicle characteristics which consumers also demand, such that requiring manufacturers to meet more stringent standards will not impair consumer demand for new vehicles because less of those other characteristics will be available. Those commenters also often highlighted the CAS language stating that consideration of consumer demand may not undermine EPCA's goal of energy conservation.

NHTSA agrees with commenters that some consumers seek out vehicle models with higher fuel efficiency, and notes that those consumers have increasing numbers of relatively high-efficiency vehicle models to choose from in the current new-vehicle market. CAFE does not affect fuel economy improvements that are supported by consumer demand—market forces will take care of that. Instead, it specifically addresses fuel economy improvements that are *not* preferred by consumers, and the agency sets standards that require manufacturers to make fuel economy improvements that consumers are not otherwise seeking. Section IV.B.3 discusses at some length the fact that alternative powertrains and higher fuel-efficiency vehicle models have proliferated widely since 2011—consumers no longer lack for choice if fuel economy is what they want. NHTSA's concern regarding consumer demand is that in an era of relatively low gasoline prices—as EIA currently projects and NHTSA has no basis to second-guess—it does not appear likely that the market for higher fuel-economy vehicles and alternative powertrains in particular will increase significantly in the rulemaking timeframe, beyond the 30-month payback period that the agencies currently use as a proxy for market demand for fuel economy. It is worth citing the CAS case at greater length here in light of its parallels: as the D.C. Circuit stated in that case,

[T]he petitioners do not challenge the consideration of consumer demand per se, but rather the weight the agency has given the factor in downgrading standards when, they argue, the principal impracticability is paying a civil penalty [*note: today, using or purchasing credits*]. Until the model years at issue here, there has been little tension between consumer demand and the fuel conservation goals of EPCA. The agency now relies on market projections in a setting in which falling gas prices have relaxed consumer demand for fuel efficiency. Earlier consideration of consumer demand in setting standards could not have alerted Congress to the agency's current application of this factor. Because Congress has not spoken clearly on the issue before us, it must be determined whether the agency's interpretation represents a reasonable accommodation of the policies embodied in the statute.

...

The agency concluded that if manufacturers had to restrict the availability of larger trucks and engines in order to adhere to CAFE standards, the effects “would go beyond the realm of ‘economic practicability’ as contemplated in the Act.”[Citation omitted.] The original projections of technological feasibility for the 1985 model year standards were based on the

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

assumption that gasoline prices would remain high and consumer demand for fuel-efficient vehicles would remain strong. No one disputes that actual circumstances have deviated from these assumptions. NHTSA acted within the reasonable range of interpretations of the statute in correcting the 1985 standards to account for these changed conditions. Consideration of product mix effects was also reasonable in setting the standards for 1986, as there is no evidence that the same trends in consumer demand will not continue.

...

In short, while it may be disheartening to witness the erosion of fuel conservation measures in the face of changes in consumer priorities, this court is nonetheless compelled to uphold the agency's standards. They are the result of a balancing process specifically committed to the agency by Congress, and, in this case, the weight given to consumer demand was not outside the range permitted by EPCA.

CAS, 793 F.2d 1322, 1340-41 (D.C. Cir. 1986). As in the situation presented in the CAS case, the agencies believed in 2012 based on the evidence then before them that fuel prices would be significantly higher than the fuel prices currently projected today. Using the fuel prices currently projected, which are lower because of the structural changes to the global oil market described at length above, ~~Figure VIII-2~~²⁹²⁹ shows the difference in annual fuel consumption for a typical driver under the augural standards, proposed standards, and final standards. As the figure shows, the difference in annual consumption (for a user that drives 14K miles per year²⁹²⁹) is fewer than 40 gallons by MY 2030—the largest difference between the alternatives. Rising fuel prices over time increase the value of those forty gallons, but the diminishing returns to successive increases in fuel economy are nonetheless evident.²⁹³⁰

²⁹²⁹ Parts of the central analysis assume a typical new vehicle is driven 14,000 miles per year, for each of the first three years it is owned. In practice, the average is slightly higher, through affected by a smaller number of users that drive much more than average. There is no single value that is representative of all households, and the National Household Travel Survey has shown lower annual usage estimates than 14,000 miles per year for a typical new vehicle.

²⁹³⁰ In general, because fuel savings are subject to diminishing returns as CAFE standards become more stringent, and per-vehicle costs increase as CAFE standards become more stringent, the relationship between per-vehicle costs and the value of fuel savings is more of a curve than a line, although the slope of the curve is reduced by the fact that we rely on EIA's forecast of rising fuel prices over time.

Figure VIII-2 - Annual Fuel Consumption for a Typical Driver

Thus, on the supply side, greater and more stable global oil supply, which reduces projected fuel prices, means that the benefits of more stringent CAFE standards are lower than they appeared to be in 2012 when the agencies believed oil supply would be scarcer and less stable, and projected fuel prices were consequently higher.

On the demand side, while NHTSA agrees that some consumers do seek out higher fuel economy, those consumers have vastly more higher fuel-economy-vehicle options than they did when the agencies wrote the 2012 final rule, as shown in Section IV above. For the other consumers who are driven more by the economics of their vehicle-purchasing decisions, NHTSA believes that they are likely making reasonably informed decisions about the new vehicle attributes they want in light of expectations about future fuel costs. This can be illustrated by examining estimated payback periods under the different regulatory alternatives, because payback period directly compares estimated future fuel savings with estimated vehicle purchase and ownership costs. A number of commenters suggested that per-vehicle cost was not a meaningful metric in isolation, because consumers would also be saving money on fuel under more stringent standards. We discuss affordability issues further below, but we present [Table VIII-7](#) ~~Table VIII-6~~ here as a comparison of per-vehicle costs to lifetime fuel savings to illustrate the point raised by commenters:

Table VIII-7 - Fuel Savings and Consumer Costs in MY 2029

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

*Fuel savings are undiscounted for purposes of estimating payback period because payback periods and discount rates are interchangeable concepts, and today's analysis represents consumer willingness-to-pay for fuel economy by a 2.5 year desired payback period.

Table VIII-7Table VIII-6 shows the differences in regulatory costs, other registration costs (taxes and financing, though the cost of insurance also increases to cover more expensive vehicles), lifetime fuel savings, and the payback relative to a MY 2017 vehicle. It is important to compare apples to apples, so in this case, because we are considering fuel costs over a vehicle's full lifetime, we need to compare that against a broader lifetime cost of ownership, instead of comparing it simply to the estimated increase in initial purchase price. Under the augural standards, the analysis projects that it would take a full five years for the undiscounted value of fuel savings to offset the estimated upfront increase in purchase cost (relative to a MY 2017 vehicle). For reference, the average new car buyer holds on to that car for about six or seven years.²⁹³¹ Naturally, this payback period, and the fuel savings on which it is based, depend upon fuel prices. Higher fuel prices shorten payback periods, while declining fuel prices lengthen them. For this analysis, the agencies have employed fuel prices estimated using the version of NEMS used to produce AEO 2019, as discussed in Section VI.

Thus, all of the regulatory alternatives considered in today's analysis result in significantly longer payback periods than the 2.5 years assumed by the agencies, the industry, and the NAS—i.e., while fuel economy would foreseeably improve in the rulemaking timeframe in the absence of regulation, it would do so at a rate slower even than the proposal would have

²⁹³¹ IHS Markit estimates the average length of new vehicle ownership at about 79 months, see <https://www.forbes.com/sites/jimgorzelay/2018/01/12/the-long-haul-15-vehicles-owners-keep-for-at-least-15-years/#4e971b576237>.

required.²⁹³² NHTSA thus does not expect that consumer demand for fuel-efficient vehicles will grow significantly in the rulemaking timeframe without regulation to prop up manufacturer sales of significantly larger volumes of more fuel-efficient models.

Manufacturer compliance shortfalls given the pace of increase in standard stringency over time are also relevant to economic practicability, and were considered as part of the 2012 final rule. Some commenters argued that it was not reasonable for NHTSA to interpret automakers' fuel economy improvements over time as evidence that less stringent standards might be maximum feasible, suggesting that evidence of improvements means that improvements are possible, and that automakers' stated difficulties with meeting more stringent standards may be overstated. Fleet fuel economy improvements over time have been possible, NHTSA agrees. NHTSA does not agree, however, that improvements thus far constitute *de facto* evidence of automakers' ability to meet rapidly increasing standards indefinitely into the future. Section IV above illustrates this clearly—many more very fuel-efficient models are available now than in 2012, while fuel prices have been trending downward on an absolute basis over the same time period. Simultaneously and relatedly, the rate at which various manufacturer fleets have been falling short of their standards has been increasing steadily. As Section IV explains, at the time of the 2012 analysis, most manufacturers were in reasonable shape in terms of compliance. The total fleet outperformed CAFE standards by a full mile per gallon—reflecting the historical trend that the full fleet *always* exceeds the average fuel economy target.²⁹³³ Of the then 45 import passenger car, domestic passenger car, and light truck compliance fleets in the 2012 model year, 26 of the fleets exceeded their fuel economy targets, while 19 failed to meet their standard.²⁹³⁴ Of those 19 fleets that failed to meet their standard, the total shortfall was 41,033,802 credits—the equivalent of \$225,685,911 in penalties.²⁹³⁵ That is no longer the case. 2016 marked the first model year in CAFE history that the entire light duty fleet failed to meet its target.²⁹³⁶ This continued in the 2017 model year (the most recent full model year of compliance data).²⁹³⁷ In the 2017 model year, of the now 42 compliance fleets,

²⁹³² While presented at the industry level, technology application and compliance simulation occur at the level of each individual manufacturer's respective fleets. Some OEMs and fleets are able to increase CAFE more easily than others—starting from more favorable positions and adding less expensive technology, or taking advantage of credit provisions, to improve the fuel economy of their fleets. However, for several OEMs, even the proposed standards are binding, and the costs associated with bringing their fleets into compliance are significant. At the level of the industry average, the cost of compliance with the proposal—and as a corollary, with the other alternatives – exceeds the 2.5 year payback for fuel economy technology, even while a small amount of overcompliance occurs at the industry level.

²⁹³³ Data from CAFE Public Information Center (PIC), https://one.nhtsa.gov/cape_pic/CAFE_PIC_Home.htm, last accessed Dec. 27, 2019.

²⁹³⁴ NHTSA MY 2011-2019 Industry CAFE Compliance, https://one.nhtsa.gov/cape_pic/MY%202011-MY_2019_Credit_Shortfall_Report_v08.pdf.

²⁹³⁵ *Id.* While we denominate shortfalls in terms of credits, that is simply for convenience, and any given manufacturer's shortfall is measured in tenths of a mile per gallon for compliance purposes.

²⁹³⁶ Data from CAFE Public Information Center (PIC), https://one.nhtsa.gov/cape_pic/CAFE_PIC_Home.htm, last accessed Dec. 27, 2019.

²⁹³⁷ *Id.*

only 14 fleets exceeded their targets.²⁹³⁸ 25 failed to meet their target, with a total shortfall of 166,715,863 credits—the equivalent of \$1,133,430,584 in penalties.²⁹³⁹ Required manufacturer reporting data shows the situation continuing to get worse in the 2018 and 2019 model years,²⁹⁴⁰ despite manufacturers' increasing ability to utilize generous credit provisions related to alternative fueled vehicles and A/C efficiency and off-cycle adjustments.

Although each year has continued to see improvements in fuel economy performance, each successive increase in stringency requires many fleets not only to achieve the new level from the resulting increase, but to resolve deficits from the prior year as well. The problem is particularly marked in the light truck fleet, where sales of lower fuel-economy vehicles have proliferated over this time period, despite availability of higher fuel-economy models. But the passenger car fleet is facing compliance challenges as well, as more consumers have shifted away from sedans and into crossover utility vehicles that are considered passenger cars for compliance purposes. While the agencies' move toward footprint based standards account for vehicle length and track width—which certainly affect fuel economy as described above—they do not account for mass-intensive increases in vehicle ride height that crossover purchasers value, the additional frontal area and higher drag at highway speeds, or the additional power required to achieve similar performance as the equivalent sedan. These issues are further exacerbated by the fact that consumers are demanding more powerful engines than the baseline efficient four cylinder versions the agencies assumed consumers would find acceptable, instead opting to upgrade to more powerful powertrains.²⁹⁴¹ If the augural standards were finalized and energy prices remain as currently projected, the shortfall situation could well erase large portions of assumed fuel savings/emissions reduction benefits from higher standards.

In the current analysis, gasoline prices are projected to rise steadily from about \$2.50/gallon in 2017 to \$3.5/gallon by 2035. While CAFE can provide some insurance against unexpected and sudden price increases, in the case of sustained, consistent increases in gasoline prices, market demand for fuel economy would outpace the standards over time. In an earlier analysis, we considered the impact of a sudden gasoline price shock in a single year, where the price of gasoline jumped from \$3.40/gallon to \$6/gallon for most of a year. If instead of that one-year spike, the price of gasoline rose steadily from current levels to \$6/gallon by 2040, the response of both consumers and manufacturers in the marketplace would cause the industry to consistently over-comply with even the augural standards.²⁹⁴² The payback assumption in this analysis, where consumers are willing to pay for any fuel economy improvement that pays for itself in the first 2.5 years of vehicle usage, would likely be too short in a world with \$6/gallon gasoline, where the cost of operating a vehicle consumed a larger share of a household's budget and even

²⁹³⁸ NHTSA MY 2011-2019 Industry CAFE Compliance, https://one.nhtsa.gov/cape_pic/MY%202011-MY_2019_Credit_Shortfall_Report_v08.pdf.

²⁹³⁹ *Id.*

²⁹⁴⁰ *Id.*

²⁹⁴¹ Mr. Rykowski's comments for EDF, for example, stated that EPA's recent Fuel Economy and CO₂ Trends Reports show clearly that manufacturers have been improving vehicle performance at the expense of fuel economy. See NHTSA-2018-0067-12018, at 31.

²⁹⁴² We simulated this response in the CAFE Model, where all other inputs were identical to the central analysis.

longer payback periods could be seen as sound investments. Thus, if it turns out that fuel prices rise steadily over the next decade, over a significantly faster rate than currently projected, the market will end up demanding more efficient vehicles and the gap between the baseline and the preferred alternative will shrink further. However, we do not currently have information that projects \$6/gallon fuel in 2040 is likely, for the reasons discussed at length above.

Given the ongoing shortfall problem illustrated above, and given the payback period estimates, the proposal might appear to be the correct answer in the absence of other considerations. NHTSA believes that the bubble concerns may be significant, and the diminishing returns of higher standards identified in Section IV above calls into question the value of pushing that bubble. Compliance shortfalls represent a growing problem with the current standards and will continue to be a problem if stringency does not converge at least somewhat more closely with what the market appears willing to bear. If industry is unable to comply with standards, that non-compliance means that the standards are not achieving what they set out to achieve in terms of fuel savings or emissions reductions, or at least they are not achieving what NHTSA estimated they would achieve. The NPRM disagreed with the idea that “if you build it, they will come”—that manufacturers would find a way to market higher fuel-economy vehicles, and consumers would eventually buy them. Comments on that topic were mixed: some commenters agreed with the NPRM’s sentiment, while other commenters argued that manufacturers’ past ability to exceed standards combined with consumers’ growing interest in fuel economy/lower emissions meant that concerns about the market’s ability to bear further increases were misplaced. The shortfall discussion above and in Section IV suggests that the NPRM’s sentiment may be accurate, but this difference in perspective highlights the core philosophical question of the CAFE program—whether consumers should choose for themselves how much fuel economy they want, or whether the government should choose for them.

EPCA/EISA directs NHTSA to conserve energy and consider the need of the U.S. to conserve energy, while simultaneously directing NHTSA to set attribute-based standards whose outcome varies depending on what consumers choose to buy, and directing NHTSA to consider economic practicability. The greater the need of the U.S. to conserve energy, the more the government should decide for consumers how much fuel economy will be in their new vehicles. Based on the information before NHTSA in this final rule, NHTSA agrees with the commenters who suggested that increasing CAFE stringency can function as “insurance” against future oil price volatility, although as illustrated above, the short-term effects of that insurance may be relatively minor and the longer-term effects may be too uncertain to consider meaningfully.

In addition to the above, as explained in the NPRM and as discussed extensively by commenters, NHTSA considers safety effects in determining maximum feasible CAFE standards. A number of commenters objected to aspects of the safety analysis, as discussed in Section VI above, and some made suggestions for improvement. In response to those comments, NHTSA took a very conservative approach in making a number of changes to the safety analysis for this final rule:

- Commenters disagreed with certain aspects of the sales and scrappage effects on the safety analysis; in response to those comments, changes have been made and the scrappage effect on fatalities is lower now than it was in the NPRM;

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- Commenters disagreed with certain aspects of mass reduction; in response to those comments, changes have been made there;
- Commenters argued that additional technologies should be accounted for; in response to those comments, many of those technologies have been added;
- Commenters argued that the NPRM did not account for crash avoidance technologies; in response to those comments, the final rule accounts for the effects of crash avoidance technologies;
- Commenters argued that the NPRM did not account for the mortality/morbidity effects of criteria pollution differences between the alternatives; in response, the final rule accounts for these effects explicitly in these values.

Overall, the final rule analysis suggests that fatalities may be lower than the NPRM analysis showed; injuries may be greater; and the safety effects overall are less than the NPRM suggested, but they are still significant. Less-stringent standards remain better for safety and are projected to save thousands of lives and prevent tens of thousands of hospitalizations, even if the amount by which they are better is lower than previously estimated.

Balancing all of the factors and issues identified above, NHTSA concludes that the need of the U.S. to conserve energy is greater than discussed in the proposal, weighing towards standards increasing, but notes that the additional incremental fuel savings, emissions reductions, and environmental benefits of higher standards is not highly significant. Regardless of the NPRM's reliance on the dictionary meaning of "to conserve," when balanced against the other factors, NHTSA does not conclude that higher standards are feasible at this time, as discussed below. There is still risk to the U.S. from circumstances outside our control that the CAFE program can mitigate, but there must also be recognition of the limited extent to which this program can address that risk, certainly without exacerbating considerable challenges currently being faced by automakers, dealers, and consumers. Economic practicability seems to be best served by slower increases, as discussed above. And while these two factors weigh in different directions, NHTSA has discretion reasonably to accommodate conflicting statutory policies. Beginning with MY 2021, the first MY addressed by this rule, Congress eliminated the obligation to increase FE standards ratably.²⁹⁴³ Thus, the appropriateness of an increase, if any, is within NHTSA's discretion based on its balancing of statutory factors. NHTSA concludes that steady increases, at the same rate for cars and trucks as suggested by several commenters, are the way to move the needle forward on fuel economy, fuel savings, and emissions reductions without, NHTSA believes, pushing the market beyond a breaking point. As both the NPRM analysis and the final rule analysis show, after MY 2020 the proposed standards are not binding at the industry level (though some manufacturers, and fleets, remain below their standard after that model year) as a consequence of market demand for fuel economy at projected gasoline prices. However, the preferred alternative, while producing slightly higher achieved CAFE levels, tracks closely to the level produced by the combination of existing CAFE standards

²⁹⁴³ Previously applied for MYs 2011-2020.

(through MY 2020) and subsequent market demand for fuel economy represented by the proposal. As a kind of insurance policy against future fuel price volatility, standards that increase at 1.5 percent per year for cars and trucks will help to keep fleet fuel economy higher than they would be otherwise if fuel prices drop again, which is not impossible over the next several years, and will enable industry to choose how to spend the capital that would otherwise be spent meeting more stringent standards on more of what consumers are demanding, which could also include more fuel economy if the market heads unexpectedly in that direction. All things considered, NHTSA determines that an increase of 1.5 percent per year is maximum feasible for both passenger cars and light trucks for MYs 2021-2026.

IX. Compliance and enforcement

A. Introduction

1. Overview

The CAFE and CO₂ emissions standards are both fleet-average standards, and for both programs, determining compliance begins by testing vehicles on dynamometers in a laboratory over pre-defined test cycles under controlled conditions.²⁹⁴⁴ A machine is connected to the vehicle's tailpipe while it performs the test cycle, which collects and analyzes the resulting exhaust gases; a vehicle that has no tailpipe emissions has its performance measured differently, as discussed below. CO₂ quantities, as one of the exhaust gases, can be evaluated for vehicles that produce CO₂ emissions directly. Fuel economy is determined from the amount of CO₂ emissions, because the two are directly mathematically related.²⁹⁴⁵ Manufacturers generally perform their own testing, and EPA confirms and validates those results by testing a sample of vehicles at the National Vehicle and Fuel Emissions Laboratory (NVFEL) in Ann Arbor, Michigan. The results of this testing form the basis for determining a manufacturer's compliance in a given model year, through the following steps:

- Each vehicle model's performance on the test cycles is calculated;

²⁹⁴⁴ For readers unfamiliar with this process, it is similar to running a car on a treadmill following a program—or more specifically, two programs. 49 U.S.C. 32904(c) states that, in testing for fuel economy, EPA must “use the same procedures for passenger automobiles [that EPA] used for model year 1975 (weighted 55 percent urban cycle and 45 percent highway cycle), or procedures that give comparable results.” Thus, the “programs” are the “urban cycle,” or Federal Test Procedure (abbreviated as “FTP”) and the “highway cycle,” or Highway Fuel Economy Test (abbreviated as “HFET”), and they have not changed substantively since 1975. Each cycle is a designated speed trace (of vehicle speed versus time) that vehicles must follow during testing—the FTP is meant roughly to simulate stop and go city driving, and the HFET is meant roughly to simulate steady flowing highway driving at about 50 mph. The 2-cycle dynamometer test results differ somewhat from what consumers will experience in the real world driving environment because of the lack of high speeds, rapid accelerations, and hot and cold temperatures evaluations with the A/C operation. These added conditions are more so reflected in the EPA 5-cycle test results listed on each vehicle's fuel economy label and on the fueleconomy.gov website.

²⁹⁴⁵ Technically, for the CAFE program, carbon-based tailpipe emissions (including CO₂, CH₄, and CO) are measured, and fuel economy is calculated using a carbon balance equation. EPA uses carbon-based emissions (CO₂, CH₄, and CO, the same as for CAFE) to calculate the tailpipe CO₂ equivalent for the tailpipe portion of its standards.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- The number of vehicles of that model that were produced is divided by the performance;
- That number, in turn is summed for all the manufacturer's model types;
- The manufacturer's total product volume is then divided by the summed value of all the model types; and
- That number represents the manufacturer's fleet harmonic average performance.

That performance is then compared to the manufacturer's unique compliance obligation (standard). This compliance obligation is calculated using the same approach that is used to determine performance, except that the fuel economy or CO₂ target value (based on the footprint of each vehicle model) is used instead of the model's measured performance value. The fuel economy or CO₂ target values for each of the vehicle models in the manufacturer's fleet and production volumes are used to derive the manufacturer's fleet harmonic average standard. Using fuel economy targets to illustrate the concept, the following figure shows two vehicle models produced in a model year for which passenger cars are subject to a fuel economy target function that extends from about 30 mpg for the largest cars to about 41 mpg for the smallest cars:

Figure IX-1 - Illustration of Vehicle Models vs. Fuel Economy Targets

If these are the only two vehicle models the manufacturer produces, the manufacturer's required CAFE obligation is determined by calculating the production-weighted harmonic

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

average of the fuel economy target values applicable at the hatchback and sedan footprints (from the curve, about 41 mpg for the hatchback and about 33 mpg for the sedan). The manufacturer's achieved CAFE level is determined by calculating the production-weighted harmonic average of the hatchback and sedan fuel economy levels (in this example the values shown in the boxes in [Figure IX-1](#) ~~Figure I-1~~, 48 mpg for the hatchback and 25 mpg for the sedan). Depending on the relative mix of hatchbacks and sedans the manufacturer produces, the manufacturer's fleet may meet the standard, or perform better than the standard (if required CAFE is less than achieved CAFE) and thereby earn credits or perform worse than the standard (if required CAFE is greater than achieved CAFE) and thereby have a shortfall that may be made up, in whole or in part, using CAFE credits, discussed below, or be subject to civil penalties. Although the arithmetic is different for CO₂ standards (which do not involve harmonic averaging), the underlying concept is the same.

There are thus, two parts to the foundation of compliance with CAFE and CO₂ emissions standards: first, how well any given vehicle model performs relative to its target, and second, how many of each vehicle model a manufacturer produces. While no given model need precisely meet its target (and virtually no model exactly meets its target in the real-world), if a manufacturer finds itself producing large numbers of vehicles that fall well short of their targets, it will have to find a way of offsetting that shortfall, either by increasing production of vehicles that exceed their targets, or by taking advantage of compliance flexibilities and incentives, or the manufacturer will be subject to civil penalties. Given that manufacturers typically need to produce for sale vehicles that consumers want to buy, and not all consumers value fuel economy, their options for pursuing the former approach can often be limited.

The CAFE and CO₂ programs both offer a number of compliance flexibilities and incentives, discussed in more detail below. For example, starting in model year 2017, manufactures have flexibility to account for efficiency improvements in air conditioning (A/C) systems and/or for the application fuel economy improving technologies that increase fuel economy in the real-world, but that are, in whole or in part, not accounted for (e.g., stop-start technology, or high efficiency alternators) using the 1975-based 2-cycle compliance dynamometer test procedures.²⁹⁴⁶ These fuel economy improvements are added to the 2-cycle performance results and are included in the calculation of a manufacturer's fuel economy in determining compliance relative to standards. In addition, for MYs 2017 – 2025, there are also two levels of compliance incentives for full-size pickup trucks with mild-HEV or strong-HEV technology or that overperform standards by 15 percent or more, or by 20 percent or more.²⁹⁴⁷ These fuel economy improvements are also included in the calculation of a manufacturer's fuel economy.²⁹⁴⁸

²⁹⁴⁶ EPA regulations provided an equivalent program beginning in MY 2012.

²⁹⁴⁷ Manufacturers also must apply the technology to a minimum percentage of their full-size pickup truck production.

²⁹⁴⁸ NHTSA characterizes any programmatic benefit manufacturers can use to comply with CAFE standards that fully accounts for fuel use as a "flexibility" (e.g., credit trading) and any benefit that counts less than the full fuel use

Some flexibilities and incentives are expressly provided for by statute, and some have been implemented by the agencies through regulations, consistent with the statutory scheme. Compliance flexibilities and incentives for the CAFE and CO₂ programs have a great deal of theoretical attractiveness: if designed properly, they can help to reduce overall regulatory costs, while maintaining or improving programmatic benefits. If designed poorly, they may create significant potential for market distortion (for instance, when manufacturers—in response to an incentive to deploy a particular type of technology—produce vehicles for which there is no natural market, such vehicles must be discounted in order to sell).²⁹⁴⁹ Manufacturers' use of compliance flexibilities and incentives requires proper governmental and industry collaboration for manufacturers to achieve the most effective pathways to compliance.²⁹⁵⁰ Overly-complicated flexibility and incentive programs can result in greater expenditure of both private sector and government resources to track, account for, and manage. Moreover, flexibilities or incentives that tend to favor specific technologies could distort the market. By these means, compliance flexibilities or incentives could create an environment in which entities are encouraged to invest in such favored technologies and, unless those technologies are independently supported by market forces, encourage rent seeking in order to protect, preserve, and enhance profits of companies that seek to take advantage of the distortions created by government mandate. Further, to the extent that there is a market demand for vehicles with lower CO₂ emissions and higher fuel economy, compliance flexibilities and incentives may cause some manufacturers to fall behind the industry's pace if they become overly reliant on them rather than simply improving the efficiency of their vehicles to meet that market demand.

If standards are maximum feasible levels, as required by statute, then the need for extensive compliance flexibilities and incentives should be low. The agencies sought comments in the NPRM on whether and how each agency's existing flexibilities and incentives might be amended, revised, or deleted to avoid the inefficiencies and market distortions discussed above. Specifically, comments were sought on the appropriate level of compliance flexibility, including credit trading, in a program that is correctly designed to be maximum feasible, in accordance with the statute. Comments were also sought on whether to allow *all* incentive-based adjustments, except those that are mandated by statute, to expire, in addition to other possible simplifications to reduce market distortion, improve program transparency and accountability, and improve overall performance of the compliance programs. The agencies considered

as an "incentive" (e.g., adjustment of alternative fuel vehicle fuel economy). NHTSA flexibilities and incentives are discussed further in Section 9.D.

²⁹⁴⁹ While many manufacturers publicly discuss their commitment to certain technologies that reduce CO₂ emissions, consumer interest in them thus far remains low, despite often-large financial incentives from both manufacturers and the Federal and State governments in the form of tax credits (i.e., natural gas or fuel-cell vehicles). It is questionable whether continuing to provide significant compliance incentives for technologies that consumers appear not to want is an efficient means to achieve either compliance or national goals (*see, e.g.*, Congress' phase-out of the AMFA dual-fueled vehicle incentive in EISA, 49 U.S.C. 32906).

²⁹⁵⁰ For these reasons, in this final rule, NHTSA is asking manufacturers to provide more detailed information on the new incentives allowed for A/C and off-cycle technologies and on credit trades for better collaboration in understanding the economic impact of these flexibilities and incentives and for the government to provide better oversight of the CAFE program.

2. Light-Duty CAFE Compliance Data for MYs 2011-2019

To understand manufacturers' potential approaches to using compliance flexibilities and incentives, CAFE compliance data for MYs 2011 through 2019 is discussed in this section. NHTSA believes that providing these data is important because it gives the public a better understanding of current compliance trends and the potential impacts that increasing CAFE standards have had on those model years and future model years addressed by this rulemaking.

NHTSA uses data from CAFE reports submitted by manufacturers to EPA or directly to NHTSA to evaluate compliance with the CAFE program. The data for MYs 2011 through 2017 include manufacturers' final compliance data that have been verified by EPA.²⁹⁵¹ The data for MYs 2018 and 2019 include the most recent projections from manufacturers' mid-model year and final-model year reports submitted to EPA and NHTSA, as required by 49 CFR Part 537 and 40 CFR 600.512-12.²⁹⁵² Because the projections do not reflect final vehicle production levels, the EPA verified final CAFE values may be slightly different than the manufacturers' projections. MY 2011 was selected as the start of the data because it represents the first compliance model year for which manufacturers were permitted to trade and transfer credits.²⁹⁵³ MY 2019 is also important because it shows the projected performance of the fleet two years after manufacturers were allowed to use new flexibilities and incentives starting in MY 2017 to address increasing CAFE standards.

Figure IX-2 through Figure IX-5 provide a graphical overview of fuel economy performance and standards. Fuel economy performance includes three parts: (1) measured performance, on the 2-cycle dynamometer test; (2) performance increases for alternative fueled vehicles, under the Alternative Motor Fuels Act of 1988 (AMFA); and (3) performance adjustments for improved A/C systems and off-cycle technologies.^{2954,2955,2956} These Figures do not account for credits earned or expected to be earned from overcompliance in prior or future model years that were used or are available for complying with CAFE standards. Graphs are included for the total fuel economy performance (the combination of all passenger cars and light trucks produced for sale during the model year) as a single fleet, and for each of the three CAFE compliance fleets: domestic passenger car, import passenger car, and light truck fleets.

²⁹⁵¹ The data contain the latest information available from manufacturers except certain low volume manufacturers complying with standards under 49 CFR part 525.

²⁹⁵² MY 2018 data come from information received in manufacturers' final reports submitted to EPA according to 40 CFR 600.512-12 and MY 2019 data come from information received in manufacturers' mid-model year CAFE reports submitted to NHTSA according to 49 CFR part 537.

²⁹⁵³ 49 CFR 535.6(c).

²⁹⁵⁴ In the Figures, the label "CAFE with Capped AMFA" represents the maximum increase each year in the average fuel economy set to the limitation "cap" for manufacturers attributable to dual-fueled automobiles as prescribed in 49 U.S.C. 32906. The labels "A/C" and "off-cycle" represents the increase in the average fuel economy adjusted for A/C and off-cycle fuel consumption improvement values as prescribed by 40 CFR 600.510-12.

²⁹⁵⁵ The Alternative Motor Fuels Act (AMFA) allows manufacturers to increase their fleet fuel economy performance values by producing dual-fueled vehicles. Incentives are available for building advanced technology vehicles such as hybrids and electric vehicles, compressed natural gas vehicles and for building vehicles able to run on dual-fuels such as E85 and gasoline. For MYs 1993 through 2014, the maximum possible increase in CAFE performance is "capped" for a manufacturer attributable to dual-fueled vehicles at 1.2 miles per gallon for each model year and thereafter decreases by 0.2 miles per gallon each model year through MY 2019. 49 U.S.C. 32906.

²⁹⁵⁶ Consistent with applicable law, NHTSA established provisions starting in MY 2017 allowing manufacturers to increase fuel economy performance-based on fuel consumption benefits gained by technologies not accounted for during normal 2-cycle EPA compliance testing (called "off-cycle technologies" for technologies such as stop-start systems) as well as for A/C systems with improved efficiencies and for hybrid or electric full-size pickup trucks.

Figure IX-2 - Total Fleet Compliance Overview for MYs 2011 to 2019

Figure IX-3 - Domestic Passenger Car Compliance Overview for MYs 2011 to 2019

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Figure IX-4 - Import Passenger Car Compliance Overview for MYs 2011 to 2019

Figure IX-5 - Light Truck Compliance Overview for MYs 2011 to 2019

As shown in Figure I-2, manufacturers' fuel economy performance for the total fleet was better than the overall CAFE standard through MY 2015. On average, the total fleet exceeded the overall CAFE standards by approximately 0.9 mpg for MYs 2011 to 2015. Comparatively, as shown in Figure I-3 through I-5, for these same model years, domestic and import passenger cars exceeded standards on average by 2.1 mpg and 2.3 mpg, respectively. By contrast, for light trucks, manufacturers on average fell below standards by 0.3 mpg.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

For MYs 2016 through 2019, as shown in the Figures, NHTSA has determined that the combined CAFE performance, including all flexibilities and incentives, of the total fleet has or is expected to be worse than the applicable CAFE standards, and increasingly so. The domestic passenger car fleet is the only compliance category expected to continue to be better than CAFE standards through MY 2018. But even the overall domestic passenger car fleet is expected to be worse than standards in MY 2019. The data show MYs 2016 through 2019 standards involve significant compliance challenges for many vehicle manufacturers. This is evident in the fact that the total fleet falls below the applicable CAFE standards on average by 0.6 mpg for these model years. Compliance challenges become even more substantial when observing individual compliance fleets. The largest individual performance shortfalls (i.e. the difference between CAFE performance values and standards) exist for import passenger car manufacturers, with an expected shortfall of 2.5 mpg in MY 2019, followed by light truck manufacturers, with a shortfall of 1.4 mpg in MY 2016.

Table IX-5 provides the numerical final CAFE performance values and standards for MYs 2004 to 2017. Notably, there was an increase in total fleet fuel economy of only 0.1 mpg for MY 2014, and no increase for MY 2016. In MY 2016, the total fleet's performance fell below the CAFE standard by 0.5 mpg. An increase in the total fleet's CAFE performance for MY 2017 was largely due to manufacturers gaining benefits from A/C and off-cycle technologies. For MY 2017, the total fleet's CAFE performance without A/C and off-cycle allowances increased by 0.1 mpg compared to MY 2016. However, even combined with new flexibilities, the total fleet's CAFE performance, for MY 2017, still falls below the CAFE standard by 0.4 mpg.

Table IX-5 - CAFE Performance and Standards for MYs 2004 to 2017

Model Year	Domestic Passenger Car		Import Passenger Car		Light Truck		Total Fleet	
	CAFE (mpg)	Standard (mpg)	CAFE (mpg)	Standard (mpg)	CAFE (mpg)	Standard (mpg)	CAFE (mpg)	Standard (mpg)
2017	39.2	38.5	39.7	39.6	28.6	29.4	33.4	33.8
2016	37.3	36.5	38.2	37.4	27.4	28.8	32.2	32.7
2015	37.2	35.2	37.3	35.8	27.3	27.6	32.2	31.6
2014	36.3	34.0	36.9	34.6	26.5	26.3	31.7	30.5
2013	36.1	33.2	36.8	33.9	25.7	25.9	31.6	30.3
2012	34.8	32.7	36.0	33.4	25.0	25.3	30.8	29.8
2011	32.7	30.0	33.7	30.4	24.7	24.3	29.0	27.4
2010	33.1	27.5	35.2	27.5	25.2	23.4	29.3	25.4
2009	32.1	27.5	33.8	27.5	24.8	23.0	29.0	25.4
2008	31.2	27.5	31.8	27.5	23.6	22.4	27.1	24.7
2007	30.6	27.5	32.2	27.5	23.1	22.2	26.6	24.6
2006	30.3	27.5	29.7	27.5	22.5	21.6	25.8	24.2
2005	30.5	27.5	29.9	27.5	22.1	21.0	25.4	23.7
2004	29.9	27.5	28.7	27.5	21.5	20.7	24.6	23.4

Figure IX-6 provides a historical overview of the industry's use of CAFE compliance flexibilities for addressing performance shortfalls.²⁹⁵⁷ MY 2016 is the latest model year for which CAFE compliance determinations are complete, and credit application and civil penalty payment determinations made by the manufacturer. Historically, manufacturers have generally resolved credit shortfalls first by carrying forward any earned credits and then applying traded credits. In MYs 2014 and 2015, the amount of credit shortfalls is almost the same as the amount of carry-forward and traded credits. Manufacturers occasionally carryback credits or opt to transfer earned credits between their fleets to resolve performance shortfalls. Trading credits from another manufacturer and transferring them across fleets occurs far more frequently. Also, credit trading has generally taken the place of civil penalty payments for resolving performance shortfalls. Only a handful of manufacturers have made civil penalty payments since the implementation of the credit trading program.²⁹⁵⁸ NHTSA expects there may be sufficient credits in manufacturers' credit accounts to resolve all import passenger car and light truck performance shortfalls expected through MY 2019. By statute, manufacturers cannot use traded or transferred credits to address performance shortfalls for failing to meet the minimum domestic passenger car standards.²⁹⁵⁹ One domestic passenger car manufacturer paid civil penalties for failing to comply with the minimum domestic passenger car standards for MYs 2016 and 2017.²⁹⁶⁰ Additional manufacturers are expected to pay civil penalty payments for failing to comply with the minimum domestic passenger cars standards for MYs 2018 through 2019.

²⁹⁵⁷ The Figure includes all credits manufacturers have used in credit transactions to date. Credits contained in carryback plans yet to be executed or in pending enforcement actions are not included in the Figure.

²⁹⁵⁸ Six manufacturers have paid CAFE civil penalties since credit trading began in 2011. Fiat Chrysler paid the largest civil penalty total over the period, followed by Jaguar Land Rover and then Volvo. See Summary of CAFE Civil Penalties Collected, CAFE Public Information Center, https://one.nhtsa.gov/cafe_pic/CAFE_PIC_Fines_LIVE.html.

²⁹⁵⁹ Congress prescribed minimum domestic passenger car standards for domestic passenger car manufacturers and unique compliance requirements for these standards in 49 USC 32902(b)(4) and 32903(f)(2).

²⁹⁶⁰ Fiat Chrysler paid \$77,268,702.50 in civil penalties for MY 2016 and \$79,376,643.50 for MY 2017 for failing to comply with the minimum domestic passenger car standards for those MYs.

Figure IX-6 - Industry Use of Compliance Flexibilities and Civil Penalty Payments

The compliance data show that the rate at which industry has been increasing fuel economy, as shown by the actual fuel economy of the overall fleet, has not kept pace with the year-over-year increases in the stringency of the standards since MY 2010. The margin of CAFE overcompliance diminished steadily through MY 2015. In MY 2016, the fuel economy of the fleet was worse than standards, and the margin of the shortfall has or is projected to become worse through MY 2019. Manufacturers have increasingly used CAFE compliance flexibilities and paid more in civil penalties to address the growing CAFE shortfalls. The data show use of these flexibilities is likely to increase at least through 2019.

3. Shift in Sales Production from Passenger Cars to Light Trucks

The notable trend in the stagnant growth in the automotive industry's CAFE performance is likely related to an increase in the purchase of light trucks beginning with MY 2013. Light trucks had a sharp spike in sales, increasing by a total of 5 percent from MYs 2013 to 2014. In MY 2014, light trucks comprised approximately 41 percent of the total sales production volume of automobiles and has continued to grow ever since. In comparison, for model year 2014, domestic passenger cars represented 36 percent of the total fleet and import passenger cars represented 23 percent. Both domestic and import passenger car sales have continued to fall every year since MY 2013. [Figure IX-7](#) shows the sales production volumes of light trucks and domestic and import passenger cars for MYs 2004 to 2017. The proportion of light trucks in the fleet, being driven by consumer demand and lower fuel prices, raises some concern for the ability of that fleet to comply with future CAFE standards. Historically, light truck fleets have fallen below their associated CAFE standards and have had larger performance shortages than either import and domestic passenger car fleets. This trend is expected to continue, even with allowance for A/C and off-cycle flexibilities. For MY 2019, NHTSA expects even greater CAFE performance shortages in the light truck and import passenger car fleets than in prior model years, based upon manufacturer's MMY reports. The combined effect of these fuel

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

economy shortages will require manufacturers to rely heavily on compliance flexibilities or pay civil penalties.

Another important factor in automobile sales production impacting CAFE performance values involves increasing trends in the volume of small SUVs and pickup trucks. These vehicles as a percentage of total fleet increased from approximately 52 percent in MY 2012 to 63 percent in MY 2017. As shown in

Figure IX-8~~Figure I-8~~, small SUVs, with 4WD and 2WD drivetrains, in particular have surpassed the sales production volumes of all other vehicle classes over these the given model years. The number of small and standard SUVs sold in the U.S. for MY 2017 nearly doubled compared to sales in the U.S. for MY 2012. During that same period, passenger car sales production as a total of vehicle sales production decreased by approximately 11 percent. The combination of low gas prices and the increased utility that SUVs provide may explain the shift in sales production. Nonetheless, if the sales of these small SUVs and pickup trucks continue to increase, NHTSA expects there will be continued stagnation in the CAFE performance of the overall fleet.

Figure IX-7 - Sales Production Volumes for MYs 2004 to 2017

Figure IX-8 - Vehicle Class Production Changes for MYs 2012 to 2017

4. Vehicle Classification

Before manufactures can comply with CAFE and CO₂ standards, they must first determine how a vehicle is classified in accordance with 49 CFR Part 523, “Vehicle Classification.” In EPCA, Congress designated some vehicles as passenger automobiles and some as non-passenger automobiles. Vehicle classification, for purposes of the light-duty CAFE and CO₂ programs, refers to whether a vehicle is classified as a passenger automobile (car) or a non-passenger automobile (light truck).^{2961, 2962} As discussed previously, passenger cars and

²⁹⁶¹ See 40 CFR 86.1803-01. For the MYs 2012–2016 standards, the MYs 2017–2025 standards, and this rule, EPA uses NHTSA’s regulatory definitions for determining which vehicles would be subject to which CO₂ standards.

²⁹⁶² EPCA uses the terms “passenger automobile” and “non-passenger automobile;” NHTSA’s regulation on vehicle classification, 49 CFR part 523, further clarifies the EPCA definitions and introduces the term “light truck” as a plainer language alternative for “non-passenger automobile.”

light trucks are subject to different fuel economy and CO₂ standards, and light trucks have less stringent standards to accommodate their utility usage.

Under EPCA and NHTSA's current regulations, vehicles are classified as light trucks either on the basis of off-highway capability or on the basis of having truck-like (utility) characteristics.^{2963, 2964, 2965} Determining whether a vehicle is capable of "off-highway operation" is a two-part determination: first, does the vehicle either have 4-wheel drive or a gross vehicle weight rating (GVWR) over 6,000 pounds, and second, does the vehicle (that has either 4-wheel drive or over 6,000 pounds GVWR) also have "a significant feature ... designed for off-highway operation."²⁹⁶⁶ NHTSA's current regulations specify that this "significant feature" requires the vehicle to meet at least four out of five ground clearance dimensions.²⁹⁶⁷ Further, to be classified as a light truck on the basis of having truck-like characteristics instead, NHTSA regulations also require the vehicle to perform at least one of the following functions: carry more than 10 persons, provide temporary living quarters, have an open bed (*i.e.*, a pickup truck), provide more cargo-carrying volume than passenger-carrying volume, or permit expanded cargo volume capacity by the removal or stowing of rear seats.²⁹⁶⁸

Over time, NHTSA has revised its light truck vehicle classification regulations and issued legal interpretations to address changes in vehicle designs. Based upon agency observations of current vehicle design trends, compliance testing and evaluation, and discussions with stakeholders, NHTSA has become aware of certain additional design changes that further complicate light truck classification determinations for the CAFE and CO₂ programs. NHTSA discussed several classification issues in the NPRM and sought comments on potential resolutions. Only a few comments were received, primarily from vehicle manufacturers, and they were aimed generally at requesting flexibility in how NHTSA applies the existing classification criteria. A summary of the comments received and NHTSA's responses for the final rule are explained in the following sections.

a. Classification Based on "Truck-Like Characteristics"

One of the "truck-like characteristics" that allows manufacturers to classify vehicles as light trucks is having at least three rows of seats as standard equipment, as long as the design also "permit[s] expanded use of the automobile for cargo-carrying purposes or other non-passenger-carrying purposes through the removal or stowing of foldable or pivoting seats so as to create a flat, leveled cargo surface extending from the forwardmost point of installation of those

²⁹⁶³ 49 USC 32901(a)(18); 49 CFR part 523.

²⁹⁶⁴ 49 CFR 523.5(b).

²⁹⁶⁵ 49 CFR 523.5(a).

²⁹⁶⁶ 49 U.S.C. 32901(a)(18).

²⁹⁶⁷ The ground clearance dimensions are: (i) approach angle of not less than 28 degrees; (ii) breakover angle of not less than 14 degrees; (iii) departure angle of not less than 20 degrees; (iv) running clearance of not less than 20 centimeters; and/or (v) front and rear axle clearances of not less than 18 centimeters each.

²⁹⁶⁸ By statute, vehicles that NHTSA, on behalf of the Secretary of DOT, "decides by regulation [are] manufactured primarily for transporting not more than 10 individuals" are passenger automobiles. 49 U.S.C. 32901(a)(18).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

seats to the rear of the automobile's interior."²⁹⁶⁹ Typically, most minivans qualify under the provision by expanding the cargo area through removable or stowable seats, and a small percentage of sports utility vehicles qualify through folding seats that use the seat backs to form a secondary "raised" cargo floor.²⁹⁷⁰ NHTSA identified two issues with this criterion that various manufacturers appear to be approaching differently. Both relate to how expanded cargo area is provided when seats are removed or stowed in the vehicle.

The first issue is how to identify the "forwardmost point of installation" and how the location impacts the available cargo floor area and volume behind the seats. Seating configurations have evolved considerably over the last twenty years, as minivan seats are now very complex in design, providing far more ergonomic functionality. For example, the market demand for increased rear seat leg room has resulted in adjustable second row seats mounted to sliding tracks. Earlier seating designs had fixed attachment points on the vehicle floor, and it was easy to identify the "forwardmost point of installation" because it was readily observable and did not change. When seats move forward and backward on sliding tracks, however, the "forwardmost point of installation" is less readily identifiable. To avoid this complication, most manufacturers maintain light truck qualification by using adjustable seats that can be removed from the vehicle and having a flat floor rearward of the front seats.²⁹⁷¹ For others, the qualification is not as apparent because new adjustable seats have been introduced that remain within vehicle to accommodate side airbags. Manufacturers designate various positions for the forwardmost point of installation in vehicles where the seat in the sliding track can be moved far enough forward to allow the entire seat to compress against the back of the front seat where it can be stowed beyond the forwardmost point of installation, while the seat cushion bottom folds towards the seatback. In some cases, manufacturers designate the forwardmost point of installation at a location in the sliding track where the seat is positioned at its *rearmost* position in the track. In others, the initial point of installation is designated at a location in the sliding track accommodating the seating position of a 75-percentile male test dummy. The amount of the flat floor surface area and cargo volume behind the seats can vary depending on which approach a manufacturer adopts.

NHTSA sought public comments in the NPRM to explore potential options for establishing the forwardmost point of installation for adjustable second row seats and to evaluate whether an additional classification criteria could be required, specifying a minimum amount of cargo volume behind the seats. Comments were received from the Auto Alliance and Fiat

²⁹⁶⁹ 49 CFR 523.5(a)(5)(ii).

²⁹⁷⁰ All minivans and a small percentage of sports utility vehicles that qualify as light trucks do so by meeting the characteristic for third row seats. As more advanced seating designs are introduced in minivans, manufacturers that wish to retain this status will need to avoid losing the expanded cargo characteristics that are the basis for the allowing minivans to be qualified as light trucks.

²⁹⁷¹ NHTSA notes that to qualify as a light truck, a vehicle still requires a flat floor from the forwardmost point of installation of removable second row seats to the rear of the vehicle.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Chrysler.²⁹⁷² Both the Auto Alliance and Fiat Chrysler commented that some flexibility is needed in determining the forwardmost point of installation that allows manufacturers to set the location of the seat attachment point to the sliding track in any manufacturer-designated position that allows for customer-ergonomics and safety, while still meeting the spirit of the expanded cargo-carrying requirement.²⁹⁷³ The Auto Alliance further commented that the forwardmost attachment point of the seat structure to the floor is still a viable method of measurement, even when there is a sliding track between the floor attachment point and the seat.²⁹⁷⁴

NHTSA did not propose any vehicle reclassifications and is not adopting a regulatory change at this time. Based on its review of the comments, NHTSA agrees that flexibility is warranted to accommodate safety and customer demand but clarifies that the regulation requires seats that are not removed to be stowed—that is, moved so as to form a cargo area behind the seats. Manufacturers can freely designate the seating location in the sliding track to establish the forwardmost point of installation. At that seat location, the forwardmost point of installation is the forwardmost attachment point of the seat structure (including any carriage structures) to the floor in the sliding track. Vehicles will be considered to meet the characteristic provided the rear of the seats can be moved forward beyond that point and the seats articulate to an unusable stowed position either in the floor of the vehicle or at the front perimeter of expanded cargo area.²⁹⁷⁵

The second issue concerns the “flatness” and “levelness” of folded rear seats that use the seat backs to form a raised cargo surface and whether the seats must form a continuous flat, leveled surface. Many SUVs have three rows of designated seating positions, where the second row has “captain’s seats” (*i.e.*, two independent bucket seats), rather than the traditional bench-style seating more common when the provision was added to NHTSA’s regulation. When captain’s seats are folded down, the seatback can form a flat surface for expanded cargo-carrying purposes, but the surface of the seatbacks may be angled (*i.e.*, at some angle slightly greater than 0°), or may be at a different level with the rest of the cargo area (*i.e.*, horizontal surface of folded seats is 0° at a different height from horizontal surface of cargo area behind the seats). Captain’s seats, when folded flat, may also leave significant gaps around and between the seats. Some manufacturers have opted to use plastic panels to level the surface and to covers the gaps between seats, while others have left the space open and the surface angled or at different levels. NHTSA sought comments in the NPRM on the following questions related to the requirement for a flat, leveled cargo surface:

²⁹⁷² The National Automobile Dealers Association commented generally that it does not support any substantial modifications to the existing passenger car and light truck fleet definitions.

²⁹⁷³ Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943.

²⁹⁷⁴ Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

²⁹⁷⁵ The front perimeter of the cargo area is the plane formed behind the front seats and extending from one side of the vehicle to the other.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

- Does the cargo surface need to be flat and level in exactly the same plane, or does it fulfill the intent of the criterion and provide appropriate cargo-carrying functionality for the cargo surface to be other than flat and level in the same plane?
- Does the cargo surface need to be flat and level across the entire surface, or are (potentially large) gaps in that surface consistent with the intent of the criterion and providing appropriate cargo-carrying functionality? Should panels to fill gaps be required?
- Certain third row seats are located on top the rear axle causing them to sit higher and closer to the vehicle roof. When these seats fold flat the available cargo-carrying volume is reduced. Is cargo-carrying functionality better ensured by setting a minimum amount of useable cargo-carrying volume in a vehicle when seats fold flat?

The Auto Alliance, Fiat Chrysler, Hyundai, Kia, and one individual, Walter Kreucher, commented on these seating issues. The Auto Alliance, Fiat Chrysler, and Walter Kreucher believed that the criteria for a “flat, leveled cargo surface” should not be interpreted to mean that a cargo surface must be flat and level in exactly the same plane.²⁹⁷⁶ The comments noted that a surface that is not exactly flat and level in the same plane can still provide substantial cargo-carrying capacity, while allowing manufacturers to provide ergonomically comfortable seats that meet safety requirements.²⁹⁷⁷ The comments stated that NHTSA should not establish a minimum amount of cargo surface area for seats that remain within the vehicle.²⁹⁷⁸ Instead, they preferred that manufacturers should be allowed to determine the methodology for providing appropriate cargo-carrying functionality without NHTSA stipulating additional requirements for flat and level surfaces or gaps and gap-filling panels.²⁹⁷⁹

The Auto Alliance and Fiat Chrysler argued that area or volume requirements are not needed, as those attributes speak to overall vehicle size and shape, which should remain a consumer choice.²⁹⁸⁰ The requirements for expanded cargo- or other non-passenger-carrying purposes are fully met in the existing regulation, which requires a flat, leveled cargo surface with two rows of seats that are folded or stowed. Fiat Chrysler also commented that potential new requirements would likely be interpreted and executed differently across manufacturers and could narrow the choice of engineering solutions and negatively affect other important vehicle attributes.²⁹⁸¹

²⁹⁷⁶ Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943; Walter Kreucher, Detailed Comments, NHTSA-2018-0067-0444.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Hyundai and Kia commented that instead of requiring panels, NHTSA could limit the size of the gaps around and between folded seats.²⁹⁸² In that case, manufacturers would have flexibility to use panels if they wish but could take other measures to narrow gaps. On the other hand, Walter Kreucher stated that NHTSA should allow gaps of any size and not require the use of panels to cover them.²⁹⁸³

NHTSA is not adopting a regulatory change at this time. NHTSA agrees with commenters that it should not require a minimum amount of cargo surface area or volume for seats that remain within the vehicle, which could be difficult to meet for certain vehicle sizes and shapes that would otherwise be considered non-passenger vehicles. NHTSA agrees that the amount of cargo volume should be a consumer choice. Setting a minimum amount of cargo area or volume could have an adverse effect on potential new car buyers.

NHTSA notes that there may also be safety considerations involved with the requirement to have a flat, leveled cargo surface area formed by seat backs. A flat, leveled cargo surface area could prevent objects from having a ramp-like surface to gain momentum in rolling backwards into the tailgate's interior surface, potentially causing stress or damage on the tailgate's latching mechanism. For these reasons, several standards exist in the industry for preventing objects from sliding, such as standards from the American Disability Act (ADA) that specify floor and ground design requirements for protecting wheelchair seated occupants. In addition, objects resting on the tailgate could become a hazard or source of injury for individuals opening the tailgate. At this time, NHTSA accepts the commenters' position that having a cargo surface area that is exactly flat and level in the same plane may not be necessary. Comments did not provide enough information for NHTSA to identify any changes to the existing requirements. Therefore, at this time, NHTSA will retain its existing provisions for the stowing of foldable or pivoting seats to create a flat, leveled cargo surface, but NHTSA may consider conducting research in the future regarding these issues. NHTSA has also determined that it should set not a limit on the size of the gaps between folded seats at this time, although it may consider adopting such limits in the future. NHTSA continues to encourage manufacturers to consider the safety implications of all aspects of their vehicle designs, including any angling of the seat back cargo surface and whether it is appropriate to offer panels as optional equipment for covering any large gap openings.

b. Issues that NHTSA has Observed Regarding Classification Based on “Off-Road Capability”

(1) Measuring Vehicle Characteristics for Off-Highway Capability

For a vehicle to qualify as off-highway capable, in addition to either having 4WD or a GVWR more than 6,000 pounds, the vehicle must have four out of five characteristics indicative of off-highway operation.²⁹⁸⁴ These characteristics are:

- An approach angle of not less than 28 degrees
- A breakover angle of not less than 14 degrees
- A departure angle of not less than 20 degrees
- A running clearance of not less than 20 centimeters
- Front and rear axle clearances of not less than 18 centimeters each

NHTSA’s regulations require manufacturers to measure these characteristics when a vehicle is at its curb weight, on a level surface, with the front wheels parallel to the automobile’s longitudinal centerline, and the tires inflated to the manufacturer’s recommended cold inflation pressure.²⁹⁸⁵ Given that the regulations describe the vehicle’s physical position and characteristics at time of measurement, NHTSA previously assumed that manufacturers would use physical measurements of vehicles. In practice, NHTSA has instead received from manufacturers a mixture of angles and dimensions from design models (*i.e.*, the vehicle as designed, not as actually produced) and/or physical vehicle measurements.²⁹⁸⁶ When appropriate, the agency will verify reported values by measuring production vehicles in the field. NHTSA currently requires that manufacturers use physical vehicle measurements as the basis for values reported to the agency for purposes of vehicle classification. NHTSA sought comment on whether regulatory changes are needed with respect to this issue.

(2) Approach, Breakover, and Departure Angles

Approach angle, breakover angle, and departure angle are relevant to determining off-highway capability. Large approach and departure angles ensure the front and rear bumpers and valance panels have sufficient clearance for obstacle avoidance while driving off-road. The breakover angle ensures sufficient body clearance from rocks and other objects located between the front and rear wheels while traversing rough terrain. Both the approach and departure angles are derived from a line tangent to the front (or rear) tire static loaded radius arc extending from the ground near the center of the tire patch to the lowest contact point on the front or rear of the

²⁹⁸⁴ 49 CFR 523.5(b)(2).

²⁹⁸⁵ *Id.*

²⁹⁸⁶ NHTSA previously encountered a similar issue when manufacturers reported CAFE footprint information. In the October 2012 final rule, NHTSA clarified manufacturers must submit footprint measurements based upon production values. 77 FR 63138 (October 15, 2012).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

vehicle. The term “static loaded radius arc” is based upon the definitions in SAE J1100 and J1544. The term is defined as the distance from wheel axis of rotation to the supporting surface (ground) at a given load of the vehicle and stated inflation pressure of the tire (manufacturer’s recommended cold inflation pressure).²⁹⁸⁷

The static loaded radius arc is easy to measure, but the imaginary line tangent to the static loaded radius arc is difficult to ascertain in the field. The approach and departure angles are the angles between the line tangent to the static loaded radius arc and the level ground on which the test vehicle rests. Simpler measurements that provide good approximations for the approach and departure angles involve using either a line tangent to the outside diameter or perimeter of the tire or a line that originates at the geometric center of the tire contact patch and extends to the lowest contact point on the front or rear of the vehicle. The first method provides an angle slightly greater than, and the second method provides an angle slightly less than, the angle derived from the true static loaded radius arc. Both approaches can be used to measure angles in the field to verify data submitted by the manufacturers used to determine light truck classification decisions.

NHTSA sought comment on what the effect would be if it replaced reference to the “static loaded arc radius” with a different term like “outside perimeter of the tire” or “geometric center of the tire contact patch.” The Auto Alliance and Fiat Chrysler offered comments. The Auto Alliance and Fiat Chrysler commented that only a measurement using the static loaded arc radius reasonably reflects the tire condition during off-road events that approach, breakover, and departure angles are quantifying. They also stated the static loaded arc radius best reflects the actual condition that exists versus the outside tire diameter.²⁹⁸⁸ Finally, the Auto Alliance commented the static loaded arc radius is easy to measure; therefore, the off-road criteria should remain tied to the static loaded arc radius.²⁹⁸⁹

After reviewing the comments, NHTSA agrees that the static loaded arc radius is the most accurate way to account for the condition of the tire and the vehicle-to-ground interaction during off-road events. NHTSA has decided to accept the Auto Alliance’s and Fiat Chrysler’s views and will retain the existing definitions for off-road angles based upon the static loaded arc radius.

(3) *Running Clearance*

NHTSA regulations define “running clearance” as “the distance from the surface on which an automobile is standing to the lowest point on the automobile, excluding unsprung weight.”²⁹⁹⁰ Unsprung weight includes the components (*e.g.*, suspension, wheels, axles, and

²⁹⁸⁷ 49 CFR 523.2.

²⁹⁸⁸ Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943.

²⁹⁸⁹ Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

²⁹⁹⁰ *Id.*

other components directly connected to the wheels and axles) that are connected and translate with the wheels. Sprung weight, on the other hand, includes all components fixed underneath the vehicle and translate with the vehicle body (*e.g.*, mufflers and subframes). To clarify these requirements, NHTSA previously issued a letter of interpretation stating that certain parts of a vehicle—such as tire aero deflectors that are made of flexible plastic, bend without breaking, and return to their original position—would not count against the 20-centimeter running clearance requirement.²⁹⁹¹ The agency explained that this does not mean a vehicle with less than 20-centimeters running clearance could be elevated by an upward force that bends the deflectors and still be considered compliant with the running clearance criterion, as it would be inconsistent with the conditions listed in the introductory paragraph of 49 CFR 523.5(b)(2). Further, NHTSA explained that without a flexible component installed, the vehicle must meet the 20-centimeter running clearance along its entire underside. This 20-centimeter clearance is required for all sprung weight components.

The agency is aware of vehicle designs that incorporate rigid (*i.e.*, inflexible) air dams, valance panels, exhaust pipes, and other components, equipped as manufacturers' standard or optional equipment (*e.g.*, running boards and towing hitches), that likely do not meet the 20-centimeter running clearance requirement. Despite these rigid features, it appears manufacturers are not taking these components into consideration when making measurements. Additionally, NHTSA believes some manufacturers may provide dimensions for their base vehicles without considering optional or various trim level components that may reduce the vehicle's ground clearance. Consistent with our approach to other measurements, NHTSA believes that ground clearance, as well as all the other off-highway criteria for a light truck determination, should use the measurements from vehicles with all standard and optional equipment installed, at the time of the first retail sale.²⁹⁹² The agency reiterates that the characteristics listed in 49 CFR 523.5(b)(2) are characteristics indicative of off-highway capability. A fixed feature—such as an air dam that does not flex and return to its original state or an exhaust that could detach—inherently interferes with the off-highway capability of these vehicles. If manufacturers seek to classify these vehicles as light trucks under 49 CFR 523.5(b)(2) and the vehicles do not meet the four remaining characteristics to demonstrate off-highway capability, they must be classified as passenger cars.

In the NPRM, NHTSA sought public comments on how to consider components such as air dams, exhaust pipes, and other hanging component features—especially those that are inflexible—as relates to running clearance and whether the agency should consider amending its definition in Part 523 to account for these components. The Auto Alliance and three automobile manufacturers—Fiat Chrysler, Hyundai, and Kia—commented on the questions. The Auto Alliance and Fiat Chrysler commented that no change is needed for the 20-centimeter running clearance requirement for fixed features of the vehicle; all fixed components must have 20-

²⁹⁹¹ See letter to Mark D. Edie, Ford Motor Company, July 30, 2012, available at [https://isearch.nhtsa.gov/files/11-000612%20M.Edie%20\(Part%20523\).htm](https://isearch.nhtsa.gov/files/11-000612%20M.Edie%20(Part%20523).htm).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

centimeter of running clearance.²⁹⁹³ They agreed that flexible components that bend without breaking and return to their original position do not count against the 20-centimeter running clearance requirement.²⁹⁹⁴ They disagreed with NHTSA's position that these requirements should apply to all vehicles with standard and optional equipment installed at the time of the first retail sale and proposed instead that the requirement should be "as shipped to the dealer."²⁹⁹⁵ Additionally, the Auto Alliance asked NHTSA to make a specific allowance for vehicles that have adjustable ride height, such as air suspension, and permit the running clearance and other off-road clearance measurements to be made in the lifted or off- road mode.²⁹⁹⁶ Hyundai and Kia urged NHTSA not to modify the definition of "running clearance," which currently is defined as "the distance from the surface on which an automobile is standing to the lowest point on the automobile, excluding unsprung weight."²⁹⁹⁷

Based upon the comments above, NHTSA has decided to retain its running clearance requirements for qualifying light trucks without change. First, running clearance means the distance from the surface on which an automobile is standing to all fixed components under the vehicle, excluding unsprung components, axle clearance components and flexible components that bend without breaking and returning to their original position as explained in NHTSA's previous interpretation. Second, NHTSA acknowledges that at this time, during validation testing for running clearance, a vehicle with optional equipment installed will only be tested "as shipped to the dealer." NHTSA has found that optional equipment can impact a vehicle's ability to comply with running clearance requirements, while optional equipment must be considered for other light truck agency validation tests unless the equipment has no impact on the outcome of the test.

(4) *Front and Rear Axle Clearance*

NHTSA regulations state that front and rear axle clearances of not less than 18 centimeters are another criterion that can be used for designating a vehicle as off-highway capable.²⁹⁹⁸ The agency defines "axle clearance" as the vertical distance from the level surface on which an automobile is standing to the lowest point on the axle differential of the automobile.²⁹⁹⁹

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The agency believes this definition may be outdated because of vehicle design changes, including axle system components and independent front and rear suspension components. In the past, traditional light trucks with and without 4WD systems had solid rear axles with center-mounted differentials on the axle. For these trucks, the rear axle differential was closer to the ground than any other axle or suspension system component. This traditional axle design still exists today for some trucks with a solid chassis (also known as body-on-frame configuration). Today, however, many SUVs and CUVs that qualify as light trucks are constructed with a unibody frame and have unsprung (*e.g.*, control arms, tie rods, ball joints, struts, shocks, etc.) and sprung components (*e.g.*, the axle subframes) connected together as a part of the axle assembly.³⁰⁰⁰ These unsprung and sprung components are located under the axles, making them lower to the ground than the axles and the differential, and were not contemplated when NHTSA established the definition and the allowable clearance for axles. The definition also did not originally account for 2WD vehicles with GVWRs greater than 6,000 pounds that had one axle without a differential, such as the model year 2018 Ford Expedition. Vehicles with axle components that are low enough to interfere with the vehicle's ability to perform off-road would seem inconsistent with the regulation's intent of ensuring off-highway capability, as Congress required.³⁰⁰¹

In light of these issues, comments were sought in the NPRM on whether (and if so, how) to revise the definition of axle clearance. NHTSA sought comments on what unsprung axle components should be considered when determining a vehicle's axle clearance. The agency questioned whether the definition for axle clearance should be modified to account for axles without differentials. NHTSA also sought comment on whether the axle subframes surrounding the axle components but affixed directly to the vehicle unibody as sprung mass (lower to the ground than the axles) should be considered in the allowable running clearance discussed above. Finally, NHTSA sought comments on whether it should consider replacing both the running and axle clearance criteria with a single ground clearance criterion that considers all components underneath the vehicle that impact a vehicle's off-road capability.

Comments were received from the Auto Alliance, Fiat Chrysler, Hyundai, and Kia. All the manufacturers that commented claimed no change is needed to the current definition, regardless of whether the axle components are sprung or unsprung masses, as the bottom of the differential is the vulnerable component.³⁰⁰² The Auto Alliance also stated there is no need to further modify the definition to account for axles without differentials. Further, the Auto Alliance does not think a single criterion that considers all components under the axle is needed and prefers to keep the existing regulation.³⁰⁰³ Fiat Chrysler and the Auto Alliance also recommended that 2WD SUVs and CUVs be reclassified back into the truck fleet, where they

³⁰⁰⁰ Unibody frames integrate the frame and body components into a combined structure.

had been placed prior to the 2011 MY. Their position is that 2WD SUVs are designed to meet the “off-road-capable” definition in NHTSA’s rules by having the required running and/or axle clearances as well as meeting other off-road dimensional criteria.³⁰⁰⁴ Hyundai stated that changing the point of measurement now would have significant development and economic impacts.³⁰⁰⁵ Kia stated that it has designed its vehicles and developed product plans in reliance on the current definitions, and those designs and product plans cannot be modified cheaply or quickly.³⁰⁰⁶

NHTSA already addressed the comments on 2WD SUVs in a previous rulemaking, and NHTSA has no additional response at this time.³⁰⁰⁷ Upon review of other comments, manufacturers did not clearly distinguish which parts of the axle sub-frames should be considered as sprung masses in order for NHTSA to understand if modifications are needed to its axle clearance requirements. Therefore, at this time, NHTSA is retaining its axle clearance requirements as currently specified. However, NHTSA still believes it is beneficial to continue efforts at defining those axle components that are sprung or unsprung masses before considering any changes to its regulatory provisions. In addition, NHTSA needs to understand any significant developmental and economic impacts that might be associated with any possible changes to its requirements. Therefore, NHTSA will consider collecting further information on these issues and may take further action related to this issue in the future.

B. EPA Compliance and Enforcement

1. Overview of the EPA Compliance Process

This section discusses EPA’s processes for its comprehensive light-duty motor vehicle program to ensure compliance with emissions standards for carbon dioxide (CO₂), nitrous oxide (N₂O), and methane (CH₄).³⁰⁰⁸ In 2010, EPA and NHTSA finalized a joint rulemaking establishing coordinated CAFE and CO₂ fleet average standards for MYs 2010-2016, which included coordinated compliance requirements and processes.³⁰⁰⁹ In its role as part of the joint program, the EPA has designed and implemented an effective compliance program capable of achieving the environmental and public health benefits promised by its mobile source CO₂ standards. EPA’s CO₂ compliance program is designed around two overarching priorities: (1) to address the Clean Air Act (CAA) requirements and policy objectives; and (2) to streamline the

³⁰⁰⁴ Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³⁰⁰⁵ Hyundai, Detailed Comments, EPA-HQ-OAR-2018-0283-4411.

³⁰⁰⁶ Kia, Detailed Comments, EPA-HQ-OAR-2018-0283-4195.

³⁰⁰⁷ No new arguments have been raised beyond those already considered in the April 6, 2006, final rule (*see* 71 FR 17566).

³⁰⁰⁸ The EPA program applies to passenger automobiles and light trucks and includes: (1) fleet average CO₂ emissions standards; and (2) fixed nitrous oxide (N₂O) and methane (CH₄) exhaust emissions standards or the option to combine N₂O and CH₄ emissions into a fleet average carbon-related exhaust emissions (CREE) value as specified in 40 CFR part 600, subpart F.

³⁰⁰⁹ *See* 88 FR 25324.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

compliance process for both manufacturers and EPA by building on existing practices wherever possible, and by structuring the program such that manufacturers can use a single data set to satisfy both CO₂ and CAFE testing and reporting requirements. The EPA and NHTSA joint compliance program recognizes, and replicates as closely as possible, the compliance protocols associated with the existing CAA Tier 2 vehicle emission standards, and the existing CAFE standards established pursuant to the Energy Policy and Conservation Act of 1975 (EPCA). In establishing the CAFE program through EPCA in the 1970s, congress gave EPA the statutorily designated responsibility for managing the testing, data collection, and calculation procedures of the CAFE program.³⁰¹⁰ EPA's experience with that program enabled EPA to integrate its CO₂ requirements with the longstanding CAFE requirements such that little to no additional test data is required and data and reporting requirements are largely synchronized. Thus, EPA requires and uses the same test data to determine a manufacturer's compliance with both the CAFE standards and the fleet average CO₂ emissions standards.

Compliance with the fleet average CO₂ standards in a given model year is determined based on testing, performed prior to production, and on actual vehicle production in that model year; as with the current CAFE standards. Manufacturers start compliance with the EPA program in advance of each model year by certifying how their products will comply with CO₂ standards and requirements as mandated by 40 CFR 86.1843-01. A representative vehicle within each test case is used to certify the model types within each manufacturer's fleet of passenger cars or light trucks.³⁰¹¹ The EPA program does not distinguish between import and domestic passenger car fleets, unlike the CAFE program. Upon successful certification of each model type, manufacturers may introduce vehicles into commerce. Next, throughout the model year, manufacturers establish test results for all the vehicles within each model type and EPA oversees the manufacturers' testing. Manufacturers conduct their CO₂ and CAFE testing over an entire model year to maximize efficient use of testing and engineering resources. Manufacturers then submit their final CO₂ and CAFE test results to EPA and EPA subsequently conducts confirmatory testing at its laboratory on a subset of the manufacturer's vehicles to determine compliance with the CO₂ standards. Emission levels can only be determined when a complete fleet profile becomes available at the close of the model year. Under this coordinated approach, the compliance mechanisms for both the CO₂ and CAFE programs are consistent and non-duplicative.

The EPA compliance program not only assesses compliance with the CO₂ standards but also assesses compliance with in-use standards. Vehicle emission standards established under the CAA apply throughout a vehicle's full useful life. EPA determines in-use standards by adding an adjustment factor to the emission results used to calculate the fleet averages.³⁰¹² The EPA program also includes requirements for manufacturers to provide warranty, defect reporting, and other emission-related component provisions promulgated in the MYs 2012–2016 rulemaking. EPA uses a variety of compliance mechanisms to validate fleet average and in-use

³⁰¹⁰ See 49 U.S.C. 32904(c).

³⁰¹¹ A model type is "a unique combination of car line, basic engine, and transmission class." 40 CFR 600.002.

³⁰¹² The values are adjusted to be 10% higher to account for test-to-test and production variability that might affect in-use test results.

standards, including pre-production certification and postproduction, in-use monitoring after vehicles enter customer service.

Under the EPA compliance program, manufacturers have a number of flexibilities and incentives to help achieve compliance. Examples include credit banking, transfers and trading, incentives for certain technologies such as battery electric vehicles and fuel cell vehicles, exemptions for certain vehicles, and alternate small manufacturer-specific CO₂ fleet average standards. In this rulemaking, EPA and NHTSA are finalizing new CO₂ and CAFE standards under which manufacturers will continue to perform the same model-level compliance processes currently required for the CO₂ and CAFE programs. These compliance processes remain in place without significant modifications. In the NPRM, EPA sought comments on possible changes to a number of its flexibilities and incentives. The following sections summarize the comments received and provide EPA's responses. For context, the EPA process for determining compliance and how manufacturers use the EPA flexibilities and incentives are explained in the following sections as well.

2. EPA's CO₂ Program Compliance

Manufacturers plan their compliance strategies far in advance of each model year. Manufacturers also contact EPA to discuss their strategies and plans for certifying each model type to comply with the CO₂ standards separately for their passenger car fleet and for their light truck fleet. CAA Section 203(a)(1) prohibits manufacturers from introducing a new motor vehicle into commerce unless the vehicle is covered by an EPA-issued certificate of conformity. Section 206(a)(1) of the CAA describes the requirements for EPA issuance of a certificate of conformity, based on a demonstration of compliance with the emission standards established by EPA under Section 202 of the Act. EPA issues certificates of conformity pursuant to Section 206 of the Act, based on (necessarily) pre-sale testing conducted either by EPA or by the manufacturer. The Federal Test Procedure (FTP or "city" test) and the Highway Fuel Economy Test (HFET or "highway" test) are used for this purpose. The certification demonstration requires emission testing that must be done for each model year.³⁰¹³ EPA's certification program for vehicles also allows manufacturers to carry certification test data over and across certification testing from one model year to the next, when no significant changes to models are made. EPA applies this policy to CO₂, N₂O, and CH₄ certification test data and allows manufacturers to use carryover and "carry across" data to demonstrate CO₂ fleet average compliance if they have done so for CAFE purposes. For test groups that are using carryover data for certification, EPA allows those test groups to carryover the N₂O compliance statement (now allowed through MY 2016) into MYs 2017 and 2018.

Because compliance with a fleet average standard depends on actual production volumes, it is not possible to determine compliance with the fleet average at the time the manufacturer applies for and receives a certificate of conformity for a test group. Instead, EPA continues to issue and compile the results of each certificate of conformity for the CO₂ program through

³⁰¹³ CAA Section 206(a)(1).

December 31st of each given model year. After the model year ends, EPA calculates the fleet average emission compliance level using actual production volumes and the CO₂ emission test values for each model type. EPA also calculates the fleet average standard based on the CO₂ emission target values from the footprint-based target curve and the production volume of each model type. EPA then compares the actual fleet average to the manufacturer's footprint-based standard to determine compliance, taking into consideration any flexibility credits and incentives like off-cycle and air conditioning credits, banked and transferred credits, and EV vehicle incentive multipliers. Final determination of compliance with fleet average CO₂ standards may not occur until one or two years after the close of the model year due to the time required for manufacturers to submit information and for EPA compliance review to be completed. A failure to meet the fleet average standard after compliance flexibilities have been exhausted could ultimately result in penalties and injunctive orders under the CAA.

a) How Does EPA Determine Compliance?

Compliance with EPA CO₂ standards is determined after the end of the model year when final compliance information on the vehicles manufactured for sale is available. As noted above, under the footprint-based standards, a manufacturer's ultimate compliance obligations are determined after the end of each model year when the production of vehicles for that model year is complete. Since the fleet average standards that apply to a manufacturer's car and truck fleets are based on the applicable footprint-based curves, a production volume-weighted fleet average requirement will be calculated for cars and trucks based on the mix and volumes of the models manufactured for sale by the manufacturer. If a manufacturer's car and/or truck fleet achieves a fleet average CO₂ level better than its car and/or truck standards, then the manufacturer generates compliance credits. Conversely, if the fleet average CO₂ level does not meet the standard, the fleet incurs compliance debits (also referred to as a shortfall). For each model year, a manufacturer also gains credits for model types equipped with certain technologies qualifying for additional flexibilities and incentives, including for A/C systems with improved efficiency or resistance to leakage, off-cycle technologies, and hybrid/electric full-size pickup trucks.

Under the EPA compliance program, a manufacturer whose fleet generates a shortfall in a given model year may have several options for using compliance credit flexibilities, including credit carryback, credit carry-forward, credit transfer, and credit trade or comply using additional credits generated by installing A/C systems with improved efficiency or resistance to leakage, off-cycle technologies, or hybrid/electric full-size pickup trucks or comply using any combination of these flexibilities and incentives. These compliance credit provisions are consistent with similar CAFE program provisions that have existed since the inception of the CAFE program or as added under EPCA and EISA through rulemaking and available starting with the 2011 or 2017 model years.³⁰¹⁴ EPA's Tier 2 program for light-duty vehicle criteria pollutant emissions uses similar credit provisions, as do many other mobile source standards

³⁰¹⁴ The benefit for A/C systems, off-cycle, and advanced full-size pickup trucks are calculated as additional credits under the EPA compliance program although are not credits under the CAFE program, rather A/C, off-cycle, and pickup truck benefits are realized as fuel consumption improvement values to increase a manufacturers' fuel economy values.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

issued by EPA under the CAA. Under the CO₂ program, if credits are unavailable in the current model year, manufacturers may carry credit deficits forward for a period of up to three model years after the deficit occurs. After that time, if credits are still not available, EPA determines that the manufacturer is not in compliance. EPA does not permit manufacturers to pay fines in lieu of compliance with applicable standards; EPA's authority under the CAA requires EPA to revoke a noncompliant manufacturer's certificate of conformity, which permits the manufacturer to sell vehicles.³⁰¹⁵ Under Section 203 of the CAA, sales of vehicles are prohibited unless the vehicle is covered by a certificate of conformity.

Compliance with the governing standards is required not only at certification, but throughout a vehicle's useful life, and compliance testing may continue after certification. Useful life standards apply an adjustment factor to account for vehicle emission control deterioration or variability in use (Section 206(a)). The useful life CO₂ standard for each model type would be the model-specific CO₂ level used in calculating the fleet average, adjusted to be 10% higher to account for test-to-test and production variability that might affect in-use test results. Section 207 of the CAA also grants EPA broad authority to require manufacturers to remedy vehicles if EPA determines there are a substantial number of non-complying vehicles. In addition, Section 205 of the CAA authorizes EPA to assess penalties of up to \$37,500 per vehicle for commission of various prohibited acts specified in the CAA. In determining the appropriate penalty, EPA must consider a variety of factors such as the gravity of the violation, the economic impact of the violation, the violator's history of compliance, and "such other matters as justice may require."

Section 203 of the CAA also describes acts that are prohibited by law. This section and the corresponding regulations apply equally to the CO₂ standards as to any other regulated emissions. Acts that are prohibited by Section 203 of the CAA include the introduction into commerce or the sale of a vehicle without a certificate of conformity, removing or otherwise defeating emission control equipment, the sale or installation of devices designed to defeat emission controls, and other related actions. EPA finalized language in the 2012 CO₂ regulations that details the specific prohibited acts under the Clean Air Act.

To aide manufacturers in the compliance process, EPA provides a number of flexibilities and incentives for manufacturers to meet compliance with fleet average CO₂ standards. These flexibilities and incentives are expected to incentivize the production of certain vehicles and provide sufficient lead time for manufacturers to make necessary technological improvements and reduce the overall cost of the program without compromising overall environmental and fuel economy objectives. The broad goal of harmonizing the two agencies' standards and compliance

³⁰¹⁵ Section 205 of the Clean Air Act authorizes EPA to assess penalties of up to \$37,500 per vehicle for violations of various prohibited acts specified in the Clean Air Act. In determining the appropriate penalty, EPA must consider a variety of factors such as the gravity of the violation, the economic impact of the violation, the violator's history of compliance, and "such other matters as justice may require." Unlike EPCA, the CAA does not authorize vehicle manufacturers to pay fines in lieu of meeting emission standards.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

processes includes preserving manufacturers' flexibilities in meeting the standards, to the extent appropriate and required by law.

b) What Exemptions and Exclusions does EPA allow?

(1) Emergency and Law Enforcement Vehicles

For EPA, police and other emergency vehicles are exempt from the CO₂ standards, as adopted for MY 2012 and later model years. Under EPCA, manufacturers are also allowed to exclude police and other emergency vehicles from their CAFE fleet and all manufacturers that produce emergency vehicles have historically done so. EPA adopted an exemption equivalent to the EPCA exemption, which allows manufacturers to exempt police and emergency vehicles upon sending notification to EPA (the same notification that is sent to NHTSA is shared). EPA continues to believe it is appropriate to provide an exemption for these vehicles because the unique features of vehicles designed specifically for law enforcement and emergency response purposes have the effect of raising their CO₂ emissions, as well as for purposes of harmonization with the CAFE program. Therefore, no comments were sought in the NPRM or received, and EPA will retain the exemption as currently existing.

(2) Small Business and Small Volume Manufacturers

Small business manufacturers meeting the Small Business Administration (SBA) size criteria set forth in 13 CFR 121.201 are exempt from EPA's CO₂ standards given that these businesses face unique challenges in satisfying the standards. For vehicle manufacturers, SBA's definition of a small business is any firm with less than 1,500 employees. This includes both U.S.-based and foreign small businesses in three distinct categories for light-duty vehicles: small volume manufacturers, independent commercial importers (ICIs), and alternative fuel vehicle converters. These businesses account for less than 0.1 percent of the total car and light truck sales in the U.S., thus the exemption has a negligible impact on overall CO₂ reductions. To ensure that EPA knows which businesses are exempt, EPA requires each such entity to submit a written declaration detailing how it qualifies as a small business under 13 CFR 121.201. The program also allows small businesses to waive their exemption and voluntarily comply with the CO₂ standards. For example, a small manufacturer of electric vehicles could choose to comply if it is interested in generating CO₂ credits and potentially participating in the credit market.

Similar to small businesses, in the MYs 2012-2016 EPA program, the agency recognized that some very small volume manufacturers (i.e., manufacturers with limited product lines and production volumes that do not meet the SBA definition of a small business) would likely find the CO₂ standards to be extremely challenging and potentially infeasible to satisfy, at least absent purchase of credits from other manufacturers. Starting with the 2017 compliance model year, eligible small volume manufacturers (SVMs) have the option to petition EPA to develop an alternative CO₂ standard for their company, determined on a case-by-case basis in a public process. For MYs 2012-2016, these same manufacturers were excluded from complying with CO₂ standards by following the same petitioning process. This flexibility mirrors the CAFE alternative standards for small business set forth in 49 CFR part 525. SVMs are exempt from meeting CO₂ standards if they have annual U.S. sales less than 5,000 vehicles. An eligible

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturer must first make a good faith effort to secure credits from other manufacturers, if they are reasonably available, to cover the emissions reductions they would have otherwise had to achieve under applicable standards. An SVM utilizing this option would then submit data and information that EPA would use in addition to other available information to establish CO₂ standards for that specific manufacturer. EPA also extended eligibility for the SVM CO₂ provisions to very small manufacturers that are owned by large manufacturers, but which are able to establish that they are operationally independent.

EPA believes its exemptions are fair and equitable for these specific types of manufacturers and, therefore, did not request comments in the NPRM to consider changes to its provisions. Consequently, EPA is retaining the existing exemptions without any further modifications.

(3) *Temporary Lead-Time Allowance Alternative Standards (TLAAS)*

By way of background, the TLAAS provisions provide additional lead time for limited volume manufacturers, whereby a specified number of vehicles are subject to a less stringent standard in either MYs 2012–2015, or (for smaller volume manufacturers) MY 2016. Manufacturers with limited product lines were noted by EPA to be especially challenged in the early years of the joint program, and needing additional lead time. Manufacturers with narrow product offerings were not able to take full advantage of averaging or other program flexibilities due to the limited scope of the types of vehicles they sell. For example, some smaller volume manufacturer fleets consist entirely of vehicles with very high baseline CO₂ emissions. Their vehicles are above the CO₂ emissions target for that vehicle footprint, but do not have other types of vehicles in their production mix with which to average. These manufacturers frequently pay fines under the CAFE program rather than meet the applicable CAFE standard.

EPA determined that these technological circumstances warranted more lead time in the form of a more gradual phase-in of standards. A manufacturer may qualify for the temporary lead-time allowance if it sold vehicles in the U.S. in MY 2009 and its U.S. vehicle sales in that model year were below 400,000 vehicles. Upon satisfying the threshold criteria, a manufacturer is permitted to treat a limited number of vehicles as a separate averaging fleet for MYs 2012–2015, which are subject to a less stringent CO₂ standard. Specifically, a standard of 25 percent above the vehicle's otherwise applicable foot-print target level will apply to up to 100,000 vehicles total, spread over the four year period of MY 2012 through 2015. Thus, the number of vehicles to which the flexibility could apply is limited. EPA is also setting appropriate restrictions on credit use for these vehicles, as discussed further in Section III. By MY 2016, these allowance vehicles must be averaged into the manufacturer's full fleet (*i.e.*, they will no longer be eligible for a different standard). EPA discusses this in more detail in Section III.B of the preamble.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

c) *What Compliance Flexibilities and Incentives Are Currently Available Under the CO₂ Program and How Do Manufacturers Use Them?*

Under Section 202 (a) of the CAA, manufacturers can use credit flexibilities to comply with CO₂ standards for passenger car or light truck compliance fleets. Similar to the CAFE program, manufacturers gain credits when the performance of a fleet exceeds its required CO₂ fleet average standard. A manufacturer's fleet performance that falls below the level of a fleet average standard earns a credit deficit. Manufacturers can carry credit deficits forward up to three model years before having to resolve the shortfall.

However, to facilitate the transition to the increasingly more stringent standards, EPA finalized under its CAA authority, a one-time CO₂ carry-forward beyond 5 years such that any credits generated from MYs 2010 through 2016 may be used to comply with light-duty vehicle CO₂ standards at any time through MY 2021. This provision does not apply to early credits generated in MY 2009.

NHTSA's program will continue the 5-year carry-forward and 3-year carryback, as required by statute. Credit "transfer" means the ability of manufacturers to move credits from their passenger car fleet to their light truck fleet, or vice versa. As part of the EISA amendments to EPCA, NHTSA was required to establish by regulation a CAFE credit transferring program, now codified at 49 CFR part 536, to allow a manufacturer to transfer credits between its car and truck fleets to achieve compliance with the standards. For example, credits earned by over-compliance with a manufacturer's car fleet average standard could be used to offset debits incurred because the manufacturer did not meet the truck fleet average standard in a given year.

Under Section 202(a) of the CAA, there is no statutory limitation on car/truck credit transfers, and EPA's CO₂ program allows unlimited credit transfers across a manufacturer's car and light truck fleets to meet CO₂ standards. EPA requested comment on a variety of "enhanced flexibilities" whereby EPA could make adjustments to current incentives and credit provisions and potentially add new flexibility opportunities to expand the means by which manufacturers may satisfy standards. Some of these additional flexibilities would not result in a reduction in program stringency, while others would incentivize technologies that could realize greater CO₂ emissions reductions over a longer term, but would result in a loss of emission benefits in the short-term, as discussed below. EPA requested comments on these topics to support the increased application of technologies that the automotive industry is developing and deploying that could potentially lead to further long-term emissions reductions and allow manufacturers to comply with standards while reducing costs.

EPA explained that one category of flexibilities, such as off-cycle credits and credit banking, involve credits that are based on real world emissions reductions and do not represent a loss of overall emissions benefits or a reduction in program stringency, yet offer manufacturers potentially lower-cost or more efficient path to compliance. Another category of flexibilities, such as incentives for battery electric vehicles, hybrid technologies, and alternative fuels, do result in a loss of emissions benefit and represent a reduction in the effective stringency of the standards to the extent the incentives are used by manufacturers. These incentives would help

manufacturers meet a numerically more stringent standard, but would not reduce real-world CO₂ emissions in the short term compared to a lower stringency option with fewer such incentives. EPA's policy rationale for providing such incentives, as articulated in the 2012 rulemaking, was that such programs could incentivize the development and deployment of advanced technologies with the potential to lead to greater CO₂ emissions reductions in the longer-term, where such technologies today are limited by higher costs, market barriers, infrastructure, and consumer awareness.³⁰¹⁶ Such incentive approaches would also result in rewarding automakers who invest in certain technological pathways, rather than being technology neutral.

Prior to the proposal, automakers and other stakeholders expressed support for this type of approach. For example, in March 2018, Ford stated, "We support increasing clean car standards through 2025 and are not asking for a rollback. We want one set of standards nationally, along with additional flexibility to help us provide more affordable options for our customers."³⁰¹⁷ Honda, in April 2018, also expressed its support for an approach that retained the existing standards while extending the advanced technology multipliers for electrified vehicles, eliminated automakers' responsibility for the impact of upstream emissions from the electric grid, and accommodated more off-cycle technologies.³⁰¹⁸

EPA's request for comments was largely based on its consideration of input from automakers and other stakeholders, including suppliers and alternative fuels industries, supporting a variety of program flexibilities.³⁰¹⁹ The following provides an overview of EPA's request for comments on several flexibility concepts, the comments EPA received, and the agency's response to those comments. After considering comments and the level of stringency of the final revised standards, EPA is not adopting new incentives in the areas of credit multipliers, new incentives for hybrid vehicles, incentives for autonomous or connected vehicles, or alternative fueled vehicles, as part of this final rule. EPA is finalizing program changes for the treatment of upstream emissions for electric vehicles, the treatment of natural gas vehicles, and off-cycle credits, as discussed below.

(1) *Credit Flexibilities*

Under the EPA program, CO₂ credits may be carried forward, or banked, for a period of five years, with the exception that MY 2010-2015 credits may be carried forward and used through MY 2021. CO₂ credits may also be traded between manufacturers and transferred between passenger car and light truck fleets similar to the CAFE program, but without any adjustment for fuel savings. Under Section 202(a) of the CAA, there is no statutory limitation on

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

credit transfers between a manufacturer's passenger car and light truck fleets, and EPA's CO₂ program allows unlimited credit transfers across a manufacturer's passenger car and light truck fleets to comply with CO₂ standards. This flexibility is based on the expectation that it will help facilitate manufacturer compliance with CO₂ standards in the lead time provided, and allow CO₂ emissions reductions to be achieved in the most cost effective way. EPA provided another credit flexibility as a one-time provision allowing manufacturers to generate credits for the 2009-2011 model years. This allowed manufacturers to take advantage of credit opportunities prior to the start of the federal tailpipe CO₂ emissions program in MY 2012.

Automakers suggested, prior to the NPRM proposal, a variety of ways in which CO₂ credit life could be extended under the CAA, like allowing automakers to carry-forward MY 2010 and later banked credits to MY 2025, extending the life of credits beyond five years, or even unlimited credit life where credits would not expire. EPA requested comments in the NPRM on extending credit carry-forward under the CO₂ program beyond the current five years, including unlimited credit life.

In the NPRM, EPA stated it believes longer credit life could provide manufacturers with additional flexibility to integrate banked credits further into their product plans and potentially reduce costs. As a result, EPA requested comments on extending credit carry-forward beyond the current five years, including unlimited credit life. General comments were received in response to the NPRM from the National Automobile Dealers Association and Volkswagen. They commented that credit carry-forward and carryback options help with annual compliance with the CO₂ program.³⁰²⁰ They stated that these mechanisms allow manufacturers to become compliant over the course of the time a credit is usable in the market.³⁰²¹ Toyota, General Motors, Fiat Chrysler, the Auto Alliance, and the Global Automakers each commented that CO₂ credits earned by manufacturers need a longer life so they may be carried forward further than the current five-year limitation.³⁰²² They asked for an unlimited period for using CO₂ credits without restrictions, since automakers have earned those credits and should be allowed to use them however they see fit.³⁰²³ They also stated that this would incentivize manufacturers to make early reductions in CO₂ emissions.³⁰²⁴ Furthermore, it was noted that credits are earned when manufacturers achieve lower CO₂ fleet average emissions than otherwise required by regulation in any given model year. They stated that this typically results from actions taken by a manufacturer to deploy specific models or more efficient technology than required, often at a higher cost. Such technologies reduce the amount of CO₂ emissions released into the atmosphere over the life of the vehicle, which could be over several decades. Therefore, the

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

resulting credit earned by a manufacturer for having made the product or technology investment that resulted in the reduced emissions should not be limited to five years.

Global Automakers, the Auto Alliance, Fiat Chrysler, and Toyota requested a one-time expiration date extension through 2026 for CO₂ credits earned in MYs 2010-2015.³⁰²⁵ They asserted that earned credits represent actual CO₂ reductions and increasing their lifespan will allow for better compliance. Conversely, Honda disagreed with the extension of MY 2010-2015 credits through 2026 because they have been selling their credits under the assumption that they would expire.³⁰²⁶ Honda stated that shorter life (soon to expire) credits are worth less than longer life credits, leading to a disadvantage for manufacturers who have already sold these credits at a lower price. Honda asserted that the one-time extension would benefit only a few automakers.³⁰²⁷ However, Honda did agree that a one-time extension through 2026 for MYs 2016-2020 CO₂ credits would assist with compliance because these credits have yet to be involved in trades.³⁰²⁸

In sum, commenters requested either unlimited allowances to carry-forward surplus credits without any expiration date, a one-time expiration date extension through 2026 for CO₂ credits earned from MY 2010 and later, or consideration for extending credit life longer than the current five-year provision. After considering the comments received, EPA has decided not to change its credit carry-forward provisions at this time, and will retain the credit carry-forward period under the CO₂ program at five years for credits generated in MYs 2016 and later. EPA stated that it did not believe any changes to its credit carry-forward provisions were warranted. EPA also acknowledges that NHTSA's CAFE program is constrained by statute to a five-year carry-forward so if EPA adopted a longer carry-forward period, it might be of limited use since the level of stringency of the CO₂ and CAFE standards is similar across the programs. Also, the analysis on which the tailpipe CO₂ emissions standards finalized today are based, assumed a five-year carry-forward period for credits.

Another reason for denying manufacturers' requests is the potential inequitable advantage a longer credit life could have for manufacturers with surplus credits, especially those with significant amounts of credits currently banked for multiple model years. Manufacturers without credits, or manufacturers who have already sold their credits at current market values based on the present five-year carry-forward credit lifespan, as Honda discussed, will be significantly disadvantaged.³⁰²⁹ These manufacturers are unlikely to be able to renegotiate the price of credit trades already made. Manufacturers with large amounts of credits would clearly be advantaged and able to distort the market in ways unfavorable to the goal of reducing emissions. EPA is concerned that these manufacturers will be able to create uncertainties in the market by being

able to infuse large volumes of credits into future model years where it may even be possible to delay some cost-effective technologies from entering production because manufacturers are relying upon these credits as an alternative pathway to compliance.

(2) *Advanced Technology Incentives*

The existing EPA CO₂ program provides incentives for electric vehicles, fuel-cell vehicles, plug-in hybrid vehicles, and natural gas vehicles. The 2012 rulemaking allowed manufacturers to use a 0 grams/mile emissions factor for all electric powered vehicles rather than having to account for the CO₂ emissions associated with upstream electricity generation, up to a per-manufacturer cumulative production cap for MYs 2022-2025. The program also includes multiplier incentives that allow manufacturers to count advanced technology vehicles as more than one vehicle in the compliance calculations. The multipliers began with MY 2017 and end after MY 2021.³⁰³⁰ Prior to the proposal, stakeholders suggested that these incentives should be expanded to support further the production of advanced technologies by allowing manufacturers to continue to use the 0 grams/mile emissions factor for electric powered vehicles rather than having to account for upstream electricity generation emissions and by extending and potentially increasing the multiplier incentives.

First, EPA requested comments on extending the use of 0 grams/mile emissions factor for electric powered vehicles.

The Auto Alliance, Global Automakers, and several manufacturers commented that upstream utility emissions come from power plants, not vehicle tailpipes, and manufacturers have no control over the feedstock used by those power plants and should not be held responsible for their upstream electricity emissions.³⁰³¹ The Auto Alliance further commented that removing upstream accounting is not an incentive for advanced technology vehicles; rather, it should be seen as a correction to remove responsibility for emissions over which the automakers have no control.³⁰³² Fiat Chrysler commented that “requiring upstream accounting could impede development of BEVs or PHEVs, as accounting of upstream emissions degrades the CO₂ performance of BEVs to the level of PHEVs, and PHEVs to the level of a conventional hybrid electric vehicle. This, in effect, disincentivizes the technology.”³⁰³³

Several other commenters also supported not counting upstream emissions and instead only counting electric powered vehicle tailpipe emissions of 0 grams/mile.³⁰³⁴ These

³⁰³⁰ The multipliers are for EV/FCVs: 2017–2019—2.0, 2020—1.75, 2021—1.5; for PHEVs and dedicated and dual-fuel CNG vehicles: 2017–2019—1.6, 2020—1.45, 2021—1.3.

³⁰³¹ See, e.g., Volkswagen, Detailed Comments, NHTSA-2017-0069-0583.

³⁰³² Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³⁰³³ Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943.

³⁰³⁴ See, e.g., NCAT, NHTSA-2018-0067-11969.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

commenters included NCAT, SAFE, BorgWarner, CALSTART, Eaton, and Edison Electric Institute.

API did not support continuing the 0 grams/mile emission factor for electricity use, commenting that by failing to factor the real contribution of upstream CO₂ emissions from electric generation, the regulatory agencies would distort the market for developing transportation fuel alternatives.³⁰³⁵ API commented that EPA should not ignore the environmental burden of upstream emissions in granting production incentives to automakers.

Manufacturers of Emission Controls Association (MECA) commented that “with the growing emphasis on real-world emission reductions, it becomes increasingly important to consider all emissions to the environment, including upstream emissions. Numerous studies have shown that in many parts of the country, the temporary 0 grams/mile upstream emissions factor is not delivered in the real-world ... MECA believes that EPA should continue to set performance-based standards that assess technology pathways based on delivering the intended emission reductions over the full well-to-wheels vehicle life cycle in the real-world.”³⁰³⁶ Motor & Equipment Manufacturers Association (MEMA) also supported a well-to-wheel fuel lifecycle approach, commenting that without this type of comprehensive assessment on the fuel impacts and comprehensive CO₂ costs, policies improperly “slant toward preferred technologies.”³⁰³⁷ Nonetheless, MEMA commented that it is not opposed to continuing to allow 0 grams/mile emissions factor for electric powered vehicles through 2026.

The Union of Concerned Scientists (UCS) commented that not accounting for upstream emissions combined with the multipliers has a significant impact on the efficacy of the standard, and extending these regulatory incentives is more likely to result in a credit giveaway than to drive additional deployment of electric vehicles.³⁰³⁸ UCS further commented that, to date, more than half of the electric vehicles sold have been in California and the states that have adopted California’s ZEV standards; however, UCS asserted, federal standards ignore the upstream emissions for all vehicles sold.

After carefully considering the wide range of comments on whether to include upstream emissions associated with electricity use in the compliance calculations for electrified vehicles, EPA has decided to allow the continued use of the 0 grams/mile emissions factor with no per-manufacturer production caps or other limitations. EPA is revising its regulations to remove the production caps and related provisions. When EPA initially adopted a production cap for manufacturers that use the 0 grams/mile emissions factor, in the rulemaking to establish CO₂ standards for MY 2012-2016 vehicles, there were no controls in place for CO₂ emissions from

electricity production.³⁰³⁹ This was also the case when EPA extended the 0 grams/mile upstream provision and revised the production caps in the rule establishing MY 2017-2025 standards.³⁰⁴⁰ However, since then, EPA has adopted a program to control CO₂ emissions from power plants.³⁰⁴¹ Emissions from the power sector have been declining and that trend is projected to continue.³⁰⁴² For these reasons, EPA no longer views the upstream emissions factor as an incentive in the same way it views a multiplier incentive which provides bonus credits. EPA agrees that, at this time, manufacturers should not account for upstream utility emissions. Therefore, EPA is adopting regulatory changes consistent with its historical practice of basing compliance with vehicle emissions standards on tailpipe emissions through model year 2026. EPA may choose to reconsider this decision in a future CO₂ rulemaking, and will reexamine the issue when establishing standards commencing with the 2027 model year.

Second, EPA requested comments on extending or increasing advanced technology incentives, including multiplier incentives, with multipliers in the range of 2.0-4.5. EPA received a wide range of comments both for and against increasing the multiplier incentives. The MY 2017-2025 CO₂ program finalized in 2012 included incentive multipliers for certain advanced technologies for MY 2017-2021 vehicles.

The Auto Alliance, Global Automakers, and several individual manufacturers commented in support of continued and increased multipliers. The Auto Alliance commented that EPA should extend and significantly expanding multipliers “to encourage a transition to these technologies while cost, range, and infrastructure challenges are addressed to encourage ongoing investments in advanced technologies.”³⁰⁴³ Global Automakers commented that multipliers should be included through MY 2026, set at values that encourage ongoing investment in advanced technologies, without diluting overall efficiency improvements in the program.³⁰⁴⁴ NCAT, Eaton, Plug-in America, Alliance to Save Energy, SAFE, and MEMA also supported additional multiplier incentives to encourage further the production and sale of advanced technology vehicles.³⁰⁴⁵

EPA also received comments against extending the multiplier credits. UCS commented that reducing the stringency of the standards lessens the need for the adoption of these vehicles and undermines the initial rationale for these credits, resulting in a significant bank of credits

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

which would further erode the benefits of these standards.³⁰⁴⁶ American Council for an Energy-Efficient Economy (ACEEE) commented that providing multiplier incentives for any longer period, or at a greater rate than those currently in place, would create windfall credits for manufacturers given the industry's current product plans.³⁰⁴⁷ Fiat Chrysler commented generally in support of a multiplier incentive, but noted that since multipliers are a CO₂-only flexibility not present in the CAFE program, greater use of multipliers would result in further disharmonizing the programs.³⁰⁴⁸ API commented against multipliers, stating that the program should be technology neutral and that regulatory agencies should not incentivize either producer or consumer investments in government-selected technologies applied to government-selected vehicle categories.³⁰⁴⁹

In this final rule, EPA is neither adopting any additional multipliers nor extending the existing multipliers scheduled to phase out after MY 2021. EPA is concerned that additional multiplier incentives beyond those already in place would reduce the emissions benefits associated with the program. EPA notes the CO₂ program already provides a significant incentive for PHEVs, EVs, and FCVs by only counting tailpipe emissions (not accounting for upstream emissions).

(3) *Special Considerations*

(a) *Incentives for Connected or Automated Vehicles*

Connected and automated (including autonomous) vehicles have the potential to impact significantly vehicle emissions in the future, with their aggregate impact being either positive or negative, depending on a large number of vehicle-specific and system-wide factors. EPA noted in the proposal that connected or automated vehicles would be eligible for credits under the off-cycle program if a manufacturer provides data sufficient to demonstrate the real-world emissions benefits of such technology applied to its vehicles. However, demonstrating the incremental real-world benefits of these emerging technologies will be challenging. Prior to the proposal, stakeholders suggested that EPA should consider an incentive for these technologies without requiring individual manufacturers to demonstrate real-world emissions benefits of the technologies. A number of stakeholders also requested that EPA consider credits for automated and connected vehicles that are placed in ridesharing or other high mileage applications, where any potential environmental benefits could be multiplied due to the high utilization of these vehicles. EPA requested comment on such incentives as a way to facilitate increased use of these technologies, including some level of assurance that they will lead to future additional emissions reductions. For example, EPA stated in the proposal that any near-term incentive program should include some demonstration that the technologies will be both truly new and

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

have some connection to overall environmental benefits. EPA further outlined and sought comment on several approaches to incentivize automated and connected vehicle technologies.

EPA received comments supporting and opposing incentives for automated and connected vehicles. The Auto Alliance commented that the agencies should incentivize the adoption of these technologies and provide for possibly additional credit once the benefits beyond the credit values have been confirmed.³⁰⁵⁰ It further commented that a growing body of modeling results, as well as real-world driving statistics, show that current automated driving technologies improve real-world fuel efficiency and reduce CO₂ emissions. SAFE commented that connected automated vehicles have tremendous potential to save lives, and when combined with ride-sharing and electric powertrains, they can also increase efficiencies and save fuel.³⁰⁵¹ SAFE argued that an initial review of the literature shows the potential for these technologies to improve fuel economy by up to 25 percent when they are optimized and aggregated alongside other traditional efficiency technologies. Toyota commented that automated vehicles, and possibly new mobility models such as ridesharing, can help attain societal goals concerning climate change, energy security, traffic congestion, and safety.³⁰⁵² Ford commented that it is supportive of credits for future connected and automated vehicles and that autonomous vehicles are considered the future of personal mobility, with many manufacturers announcing plans to release autonomous-capable vehicles in the near term.³⁰⁵³ Ford added that these vehicles have the potential to not only provide meaningful real-world CO₂ and fuel economy benefits, but also add true societal benefit for the public good by providing transportation to those who would otherwise not have access. General Motors and Jaguar Land Rover commented in favor of additional credits for vehicles placed in ride-sharing or high mileage applications.³⁰⁵⁴

CARB asserted new compliance flexibilities for autonomous vehicles are not appropriate.³⁰⁵⁵ It stated that manufacturers are already anticipating bringing autonomous technologies to their fleets, making these flexibilities unnecessary.³⁰⁵⁶ Conversely, SAFE commented that autonomous vehicles will lead to new jobs and better worker productivity. It stated that these vehicles will also reduce congestion and lead to safer travel.³⁰⁵⁷

Other commenters opposed incentives for automated and connected vehicles, generally commenting that while the technologies are promising, the impacts of the technologies remain highly uncertain and therefore incentives are not appropriate. ACEEE commented that EPA should not incentivize technologies such as automated vehicle technology or ridesharing

services, unless and until it can be demonstrated that such an incentive will result in emissions reduction benefits and will not undermine the existing standards.³⁰⁵⁸ ACEEE believes that there currently exists no real-world data to justify granting of off-cycle credits for automated vehicle technologies, and that providing automakers credits for deploying technologies which are driven by demands other than fuel savings and emissions reduction only allows them to make fewer real-world emissions reductions elsewhere. ACEEE further stated that while automated vehicles promise all-new possibilities and efficiencies in transportation and the use of infrastructure, the net impact on transportation sector energy use and emissions is unknown.

UCS commented that the “evidence to-date does not warrant incentivizing such technologies—there is no provable environmental benefit of such technologies, and the agencies have previously correctly acknowledged that any such potential impacts would be related to indirect benefits, which raise serious concerns about compliance and enforcement to ensure the integrity of the program.”³⁰⁵⁹ Honda commented that there remains considerable uncertainty in the literature regarding the energy and environmental benefits (or negative benefits) of connected/automated vehicle technology.³⁰⁶⁰ Honda commented that if technology benefits can be verified under robust, repeatable conditions, they should warrant off-cycle credits under the existing off-cycle program. Honda does not believe credits should be granted for application of technology alone.

CARB commented that new compliance flexibilities (or off-cycle credit categories) for automated vehicles are not appropriate at this time.³⁰⁶¹ CARB believes that, although the technology is widely expected to provide safety and mobility benefits, automakers are expected to bring the technology to market regardless, so incentives are unnecessary, and it is not established that these technologies will reduce emissions given their potential for high annual mileage. Resources for the Future commented they do not see a rationale for providing special credits to automated vehicles since such vehicles could increase or decrease emissions.³⁰⁶² Competitive Enterprise Institute (CEI) commented that some connected and/or automated vehicle technology applications—namely platooning—may improve fuel efficiency through improved aerodynamics and thus reduce CO₂ emissions; however, such applications to date are limited to heavy-vehicle prototypes beyond the scope of this rulemaking and in any event should be subject to verification prior to any award of off-cycle credits.³⁰⁶³ CEI commented further: “We urge EPA to preserve the existing off-cycle program requirement that manufacturers demonstrate CO₂ emissions reductions prior to the award of credits, rather than picking technology winners and losers that have nothing to do with fuel economy or emissions.” National Association of Truck Stop Operators (NATSO) commented against incentives, stating that although automated vehicles have the potential positively to transform transportation (and

indeed day-to-day life) in the U.S., there are also a number of complexities and potential costs associated with them.³⁰⁶⁴

EPA is not adopting new incentives for automated and connected vehicles. While EPA agrees there may be potential for such technologies to reduce emissions long-term, depending on how the technologies are developed, implemented, and used, EPA remains concerned about the high degree of uncertainty regarding the impacts of the technologies and potential loss of emissions reductions associated with such incentives. EPA agrees with the comments that, at this time, it is more appropriate for manufacturers to seek credits through the existing off-cycle credits program where manufacturers would be required to provide data demonstrating direct emissions improvements for the technologies.

(b) Natural Gas Vehicle (NGV) Credits

Vehicles that are able to run on compressed natural gas (CNG) are eligible for an advanced technology multiplier credit for MYs 2017-2021, as discussed in the Advanced Technology Incentives section above. Dual-fueled natural gas vehicles, which can run either on natural gas or on gasoline, also may use utility factors higher than 0.5 when weighting tailpipe emissions measured over the test procedures while operating on natural gas and gasoline test fuels if the vehicles meet minimum design criteria, including minimum CNG range requirements. Prior to the proposal, EPA received input from several industry stakeholders that supported expanding these incentives to stimulate production of vehicles capable of operating on natural gas, including treating incentives for natural gas vehicles on par with those for electric vehicles and other advanced technologies, and adjusting or removing the minimum range requirements for dual-fueled CNG vehicles. EPA requested comments on these potential additional incentives for natural gas fueled vehicles.

Among comments received regarding incentives for NGVs, Ariel Corporation and VNG together commented that NGVs can be effectively promoted by providing a level playing field and regulatory parity with EVs.³⁰⁶⁵ They stated, “an effective alternative compliance pathway for NGVs can be established with a few simple changes to the regulations including applying the ‘0.15 divisor’ to emissions calculations, which would harmonize EPA’s regulations with the statutory CAFE program, and recognize the real-world emissions benefits of RNG [renewable natural gas], and provide NGVs with reasonable parity with EVs.” Ariel and VNG commented also that EPA should offer advanced technology production multipliers for NGVs on par with EVs and FCVs, with NGVs receiving these incentives at the same level and for the same duration as electric and fuel-cell vehicles. These commenters believe that while NGVs have lower technology hurdles than these vehicles, they face similar infrastructure challenges and offer similar or superior emissions benefits through the use of RNG.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association commented in a joint submission that NHTSA and EPA should use this rulemaking opportunity to expand incentives for NGVs and thereby increase the availability of NGVs in the light-duty sector, particularly for pickup trucks, work vans, and sport utility vehicles.³⁰⁶⁶ These commenters also submitted comments supporting additional incentives for full-size pickup NGVs and incentives for vehicles equipped to be converted to operate on natural gas. Coalition for Renewable Natural Gas, et al., commented that allowing 0 grams/mile accounting for electricity use is favorable to electric vehicles because it allows electric vehicle manufacturers to take credit for anticipated improvements in emissions associated with the electric grid resulting from increased use of natural gas and renewable energy.³⁰⁶⁷ It further commented that given the significant amount of renewable natural gas currently being used and projected to be used in future years, using a factor of 0.15 or even greater to offset NGV emissions is warranted because RNG use reduces carbon dioxide emissions by 85 percent or more in most cases. Ingevity similarly commented in support of EPA including a 0.15 multiplier incentive for purposes of CO₂ compliance parity between natural gas and electric dual-fuel vehicles as necessary and critical to promote the commercialization of light-duty natural gas vehicles and stimulate the increased utilization of RNG. Ingevity added that growth in the natural gas vehicle market is necessary to meet future RFS obligations.³⁰⁶⁸

United States Senator James M. Inhofe commented that “even if all current incentives for EVs are eliminated, EVs still have a compliance advantage going forward. This is because the policy and technical approaches underlying the [CO₂] regulations embedded preferential treatment for the previous administration's favored technology. I respectfully ask you not to give NGVs preferential treatment, but to level the playing field to allow the marketplace to determine the future of NGV adoption and not the federal bureaucracy. To achieve this parity, reinstating the 0.15 [CO₂] multiplier is essential.”³⁰⁶⁹

In addition to supporting the application of a 0.15 factor, some in the natural gas industry also commented in support of production multipliers for NGVs. Ariel and VNG commented that EPA should offer advanced technology production multipliers for NGVs on par with EVs and FCVs, with NGVs receiving these incentives at the same level and for the same duration as electric and fuel cell vehicles. Ingevity commented that dual-fuel and dedicated NGV multipliers should be extended through 2025 as an effective way to promote the commercialization of these kinds of vehicles by the automakers. NGV America et al. commented that “NGVs, both dedicated and dual-fuel, should be provided with the same vehicle production multiplier credits as have previously been, and continue to be, provided to EVs and FCVs. Given that the expected and likely range capabilities of NGVs will generally exceed EV ranges (including natural gas dual-fuel vehicles that significantly outperform the range

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

capabilities of PHEVs which justifiably enjoy a lower multiplier as compared to EVs), the vehicle production multipliers that are used for EVs should be applied to NGVs, including dual fuel NGVs. Specifically, dedicated and dual-fuel NGVs (or all covered advanced technology vehicles) should receive a base multiplier of 2.0 (or any such higher multiplier afforded to EVs/FCVs) for at least model years 2019 through 2021 and the same multipliers afforded to EVs/FCVs thereafter through 2025.”

National Association of Convenience Stores (NACS) and the Society of Independent Gasoline Marketers of America (SIGMA) commented, “the Associations urge you to treat all fuels and technologies equally, including NGVs, EVs, and petroleum-based motor fuels. It is the role of the Agencies to set performance specifications via notice-and-comment rulemaking to ensure that they are appropriate. Once the specifications are set, however, it should be up to the market to determine how best to meet them.”³⁰⁷⁰

UCS commented that natural gas is a potent greenhouse gas, and any direct emissions of methane pose a significant threat to any effort to limit climate change.³⁰⁷¹ UCS stated, “these direct emissions upstream significantly undermine any potential benefit that could come from the pump-to-wheel benefits of displacing gasoline or diesel with natural gas.” UCS also commented, “furthermore, the technology underpinning any natural gas-powered vehicle is exceptionally mundane—natural gas has been deployed previously in vehicles like the Honda Civic, and aftermarket CNG conversions have long been available on the market. Again, there is no critical hurdle to overcome with CNG powered vehicles, and there is little if any benefit to any such incentives. We strongly recommend that EPA eliminate all incentives for natural gas vehicles and instead ensure such vehicles are credited commensurate with their impact on the environment.” CARB also commented that new compliance flexibilities for NGVs are not appropriate at this time.³⁰⁷²

The Natural Gas Vehicles of America (NGV America) commented that there is no incentive under existing EPA and NHTSA regulations for an automaker to sell vehicles equipped to be converted to operate on natural gas (so-called “gaseous-prep vehicles”), even though selling such vehicles often results in the increased availability of alternative fuel vehicles. Today, most alternative fuel conversions are performed on newly manufactured gaseous-prep vehicles or vehicles that have been equipped by the original equipment manufacturers with hardened valves, valve seats, pistons, and piston rings. As an example, most of Ford’s commercial truck line-up is available as gaseous-prep, and many such vehicles are converted to natural gas or propane by qualified vehicle manufacturers. Converting these vehicles, producing an assembly-line gaseous-prep vehicle, and sharing diagnostic information are critical to ensuring that aftermarket conversions perform well in-use and do not degrade the vehicle’s emission control equipment. Given the complexity of today’s automobiles, it is virtually impossible to legally convert new vehicles without this level of cooperation from vehicle manufacturers.

³⁰⁷⁰ Joint submission on behalf of NACS and SIGMA, Detailed Comments, EPA-HQ-OAR-2018-0283-5824.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NGVAmerica further commented that providing a regulatory incentive for automakers to sell these vehicles would expand the availability of gaseous-prep vehicles and increase consumer choice for alternative fuel vehicles. EPA, therefore, should provide a credit for selling such vehicles if the automaker can verify that the vehicles were subsequently upfitted or converted using an EPA certified alternative fuel system. Given the significant cost associated with certifying vehicles and installing natural gas tanks, there is very little likelihood that such an incentive would be abused by automakers. As with credits for original equipment manufactured vehicles, the utility factor for these vehicles would be based on the range of the vehicle when operating on natural gas. In this way, vehicles with larger range would earn more credit and vehicles with reduced range would earn less credit.

Regarding comments that EPA should provide additional credits to auto manufacturers for the potential use of RNG due to upstream benefits associated with the production of RNG by applying a 0.15 factor, EPA disagrees because auto manufacturers would not be required to ensure such fuels are used in the vehicles they produce over the life of those vehicles. Commenters provided a rationale for why they believe all NGVs produced in the future will be fueled with RNG, but EPA believes there is no assurance that this would be the case. If fossil fuel-based natural gas is used in the vehicles, the environmental benefits asserted by the commenters would not exist and the substantial vehicle incentives recommended by the commenters would result in a loss of environmental benefits. EPA does not believe it is appropriate to attribute most or all of the potential benefits of the production and use of RNG to the vehicle manufacturer. EPA's Renewable Fuel Standards (RFS) already appropriately credit RNG use as compared to fossil fuel-based natural gas. The RFS program provides a substantial incentive for RNG production, and those incentives may lead to even lower fuel pricing and greater demand for RNG as vehicle fuel, and for NGVs in the future. The RFS program also can provide incentives for liquid cellulosic fuels, advanced bio-diesel, and other types of renewable transportation fuels. Consistent with EPA's decision not to include upstream emissions associated with electricity use for EVs and PHEVs discussed above, EPA believes it is appropriate at this time to maintain the focus of the light-duty vehicle GHG standards on the capabilities of the vehicle to control emissions, and not rely on lifecycle fuel characteristics as a basis for developing specific vehicle incentives, particularly where those fuels are already incentivized by the RFS program.

After considering comments regarding incentive multipliers for NGVs and the current lack of light-duty NGV offerings by OEMs in the market, EPA has decided to include a multiplier incentive of 2.0 for MY 2022-2026 dedicated and dual-fuel NGVs. This multiplier will go into effect when the previously established multipliers expire, thus extending the multiplier for NGVs for 5 years beyond those previously established for NGVs. While other alternative fuel vehicles that were provided multiplier incentives are increasingly available in the light-duty marketplace, no OEM is currently offering light-duty NGVs. Since Honda ended production of the CNG version of the Honda Civic at the end of MY 2015, there have been no OEM NGV offerings available to consumers. EPA continues to believe that NGVs could be an important part of the overall light-duty vehicle fleet mix, and such offerings would enhance the diversity of

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

potentially cleaner alternative fueled vehicles available to consumers.³⁰⁷³ EPA believes it is appropriate to extend the availability of a production multiplier through MY 2026 for both dual-fuel and dedicated NGVs to potentially help spur their re-introduction by OEMs in the light-duty vehicle market.

EPA also received comments on the application of the regulatory utility factor. For dual-fuel vehicles, emissions are measured on both fuels (e.g., gasoline and natural gas) and weighted using a factor referred to in the regulations as a utility factor. To use a utility factor for natural gas greater than 0.5, a dual-fuel NGV must meet design criteria requiring the vehicle to have a natural gas to gasoline driving range of 2:1. The vehicle must also preferentially operate on natural gas until the natural gas tank is empty. EPA adopted these design criteria as part of the 2012 final rule to help ensure vehicles using a utility factor of higher than 0.5 would likely be fueled with and use natural gas most of the time on the road. At that time, EPA was concerned that natural gas refueling may be much more inconvenient for drivers relative to electric charging for PHEVs due to a lack of CNG refueling stations (or home refueling, compared to the availability of home chargers for many PHEVs) and, therefore, dual-fuel vehicles with limited driving range on natural gas would likely frequently operate on gasoline.

EPA received comments regarding the design criteria. Ingevity commented that it has developed a low-pressure (900 psi) adsorbed natural gas (ANG) fuel storage technology that allows vehicles to be refueled using an affordable and reliable low-pressure natural gas fueling appliance.³⁰⁷⁴ Ingevity commented that ANG will allow for a distributed refueling network at users' homes and businesses, just like electrical recharging equipment has been installed for PHEVs over the last several years. Ingevity commented that the design criteria for dual-fuel NGVs that were established in the MYs 2017-2025 final rule "make it impossible to reasonably and affordably manufacture a dual-fuel NGV that can fully utilize the utility factor (UF) approach for determining fuel economy and [CO₂] emissions." Ingevity recommended that the design criteria for dual-fuel NGVs be removed and that the utility factor be based only on the range of the NGV on natural gas, equivalent to the treatment of PHEVs. MECA submitted similar comments regarding ANG technology.³⁰⁷⁵

Ariel and VNG also commented that design criteria imposed on dual-fuel NGVs add unnecessary costs and complexity, and currently are arbitrarily applied only to dual-fuel NGVs, and not to their dual-fuel hybrid counterparts.³⁰⁷⁶ NACS, SIGMA, and NATSO also recommended that EPA remove eligibility requirements associated with the utility factor.³⁰⁷⁷

After considering the comments, EPA is removing the design criteria from the regulations and thereby allowing higher utility factors to be used for dual-fuel natural gas

³⁰⁷³ The CNG Honda Civic had approximately 20 percent lower CO₂ than the gasoline Civic in MY 2015.

³⁰⁷⁴ Ingevity, Detailed Comments, NHTSA-2018-0067-8666.

³⁰⁷⁵ See MECA, Detailed Comments, NHTSA-2018-0067-11999.

³⁰⁷⁶ Joint Submission from Ariel Corp. and VNG, Detailed Comments, NHTSA-2018-0067-7573.

³⁰⁷⁷ Joint submission on behalf of NACS and SIGMA, Detailed Comments, EPA-HQ-OAR-2018-0283-5824; NATSO, Detailed Comment, EPA-HQ-OAR-2018-0283-5484.

vehicles based solely on driving range on natural gas, as is the case for PHEVs. The utility factor represents a reasonable way of weighting the emissions of a dual-fuel vehicle on each fuel to derive a single emissions value when including the dual-fuel vehicles in a manufacturer's fleet average compliance determination. Ideally, the utility factor would match the use of each fuel in real-world vehicle operation. The utility factor is not meant to incentivize the adoption of a particular technology, so it differs fundamentally from incentives such as multipliers. With the development of low-pressure natural gas vehicle fueling system technology since the 2012 final rule, EPA's concerns regarding limited fueling infrastructure that led the agency to adopt the design criteria in the 2012 rule are significantly diminished. EPA believes that low-pressure fueling is a new advancement that offers the potential for more convenient refueling for individuals or businesses similar to that for PHEVs. EPA expects owners of dual-fuel CNG vehicles preferentially to seek to refuel and operate on CNG fuel as much as possible, both because the owner would have to pay a higher vehicle price for the dual-fuel capability, and because CNG fuel is considerably cheaper than gasoline. With the opportunity for relatively low-cost on-site refueling at homes or businesses, EPA expects such vehicles to be refueled with natural gas similar to how people refuel PHEVs. Vehicle purchasers that choose high pressure vehicle systems over low pressure systems would likely do so only if they have ready access to a high pressure refueling system, for example, at a fleet's central fueling location. Removing the design criteria for dual-fuel natural gas vehicles also addresses the concerns of some commenters regarding the differing treatment of PHEVs and dual-fuel NGVs.

EPA believes that with the advancement of technology offering the potential for more flexible refueling of NGVs, removing the design criteria is a reasonable change to the regulations. This regulatory change will apply starting with MY 2021. MY 2021 will provide sufficient time for orderly implementation and EPA is not aware of any dual-fuel NGVs emissions certified for MYs 2019-2020 that would otherwise be affected if this change were to be implemented sooner.

EPA received comments that vehicle conversions and "gaseous-prep" vehicles should be eligible for credits. As noted above, EPA is not adopting any new incentives for NGVs. In response to comments on vehicle conversions, alternative fuel converters are not required to meet fleet average standards but instead may comply with 40 CFR part 85 subpart F regulations providing a tampering exemption. Fleet average standards are generally not appropriate for fuel conversion manufacturers because the "fleet" of vehicles to which a conversion system may be applied has already been accounted for under the OEM's fleet average standard. Alternative fuel converters are not manufacturing new vehicles, but are converting existing vehicles that have already been certified by the OEM. CO₂ credits are available to OEMs based on fleet emissions performance compared to the fleet average standards and therefore conversions are not eligible for these credits. EPA did not propose to change and is not changing the exemption process promulgated in 40 CFR part 85 subpart F. Because fuel conversions are not required to meet the fleet average standards, credits generated under those standards are not available. Regarding gaseous-prep vehicles, these vehicles are not NGVs at initial sale and therefore are not eligible for NGV incentives. Instead, they are included in the OEM's fleet as gasoline-only vehicles. EPA disagrees with the commenters that such vehicles should be eligible for NGV incentives at time of initial sale if the vehicle is later converted to natural gas since the OEM does not measure

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

the emissions of the vehicle on natural gas at time of certification and is not responsible for the emissions performance of the vehicle on natural gas over the life of the vehicle.

C. NHTSA Compliance and Enforcement

1. Overview of the NHTSA Compliance Process

Consumer choice drives the mixture of automobiles on the road. Manufacturers largely produce a mixture of vehicles to meet consumer demand and address compliance with CAFE standards through the application of fuel economy improving technologies to those vehicles, and by using compliance flexibilities and incentives that are available in the CAFE program. As discussed earlier in this notice, each vehicle manufacturer is subject to separate CAFE standards for passenger cars and light trucks, and for the passenger car standards, a manufacturer's domestically-manufactured and imported passenger car fleets are required to comply separately.³⁰⁷⁸ Additionally, domestically-manufactured passenger cars are subject to a statutory minimum standard.³⁰⁷⁹ CAFE program flexibilities are largely provided for in statute.

Compliance with the CAFE program begins with manufacturers submitting required reports to NHTSA in advance and during the model year that contain information, specifications, data, and projections about their fleets.³⁰⁸⁰ Manufacturers report early product projections to NHTSA describing their efforts to comply with CAFE standards per EPCA's reporting requirements.³⁰⁸¹ Manufacturers' early projections are required to identify any of the flexibilities and incentives manufacturers plan to use for air-conditioning (A/C) efficiency, off-cycle and full-size pickup truck advanced technologies. EPA consults with NHTSA when reviewing and considering manufacturers' requests for fuel consumption improvement values for A/C and off-cycle technologies that improve fuel economy. NHTSA evaluates and monitors the performance of the industry using the information provided. NHTSA also audits manufacturers' projected data for conformance and verifies vehicle design data through testing to ensure manufacturers are complying as projected. After the model year ends, manufacturers submit final reports to EPA, including final information on all the flexibilities and incentives allowed or approved for the given model year.³⁰⁸² EPA then calculates the fuel economy level of each fleet produced by each manufacturer, and transmits that information to NHTSA.³⁰⁸³

³⁰⁷⁸ 49 U.S.C. 32904(b).

³⁰⁷⁹ 49 U.S.C. 32902(b)(4).

³⁰⁸⁰ 49 U.S.C. 32907(a); 49 CFR 537.7.

³⁰⁸¹ 49 U.S.C. 32907(a).

³⁰⁸² For example, alternative fueled vehicles get special calculations under EPCA (49 U.S.C. 32905-06), and fuel economy levels can also be adjusted to reflect air conditioning efficiency and "off-cycle" improvements, as discussed below.

³⁰⁸³ 49 U.S.C. 32904(c)-(e). EPCA granted EPA authority to establish fuel economy testing and calculation procedures; EPA uses a two-year early certification process to qualify manufacturers to start selling vehicles, coordinates manufacturer testing throughout the model year, and validates manufacturer-submitted final test results after the close of the model year.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NHTSA notes that some manufacturers have submitted and/or resubmitted requests for A/C and off-cycle benefits after EPA final reports are completed or nearly completed and, in those cases, such submissions are causing considerable delays in EPA's ability to finalize CAFE reports. Late and revised submissions can place significant burdens on the government in order to reassess a manufacturer's CAFE performances and standards and can also cause significant impacts on previous compliance model years. In the following sections, EPA and NHTSA are incorporating regulatory modifications or providing guidance to help manufacturers expedite approvals and to facilitate the governments processing of the flexibilities and incentives.

NHTSA determines each manufacturer's obligation to comply with applicable model year's CAFE standards and notifies the manufacturer if any of its fleet performances fall below standards. Manufacturers must submit plans detailing the compliance flexibilities to be used to resolve any possible noncompliances or may pay civil penalties to address any deficits for falling below standards. NHTSA periodically releases data and reports to the public through its CAFE Public Information Center (PIC) based on information in the EPA final reports for the given compliance model year, and based on the projections manufacturers provide to NHTSA for the next two model years.³⁰⁸⁴

2. NHTSA's CAFE Program Compliance

EPCA and EISA specify several flexibilities and incentives that are available to help manufacturers comply with CAFE standards. Some flexibilities are defined, and sometimes limited by statute – for example, while Congress allowed manufacturers to transfer credits earned for over-compliance from their car fleet to their truck fleet and vice versa, Congress also limited the amount by which manufacturers could increase their CAFE levels using those transfers.³⁰⁸⁵ Consistent with the limits Congress placed on certain statutory flexibilities and incentives, NHTSA crafted and implements the credit transfer and trading regulations authorized by EISA to help ensure that total fuel savings are preserved when manufacturers exercise statutory compliance flexibilities.

NHTSA and EPA have previously developed other compliance flexibilities and incentives for the CAFE program consistent with the statutory provisions regarding EPA's calculation of manufacturers' fuel economy levels. As discussed previously, NHTSA finalized in the 2012 final rule, for MYs 2017 and later, an approach for manufacturers' "credits" under EPA's program to be applied as fuel economy "adjustments" or "improvement values" under NHTSA's program for: (1) technologies that cannot be measured or cannot be fully measured on the 2-cycle test procedure, i.e., "off-cycle" technologies; and (2) A/C efficiency improvements that also improve fuel economy but cannot be measured on the 2-cycle test procedure. Additionally, both agencies' programs give manufacturers compliance incentives for utilizing specified technologies on pickup trucks, such as pickup truck hybridization.

³⁰⁸⁴ NHTSA CAFE Public Information Center, https://one.nhtsa.gov/cafe_pic/CAFE_PIC_Home.htm.

³⁰⁸⁵ See 49 U.S.C. 32903(g).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The following sections outline how NHTSA determines whether manufacturers are in compliance with the CAFE standards for each model year, and how manufacturers may use compliance flexibilities, or address noncompliance by paying civil penalties. As addressed above, some compliance flexibilities are expressly prescribed in statute and some are implemented consistent with EPCA's provisions regarding calculation of fuel economy. NHTSA proposed new language updating and clarifying existing regulatory text in this area as part of the NPRM. NHTSA also sought comments in the NPRM on these changes, as well as on the general efficacy of these flexibilities in the fuel economy and CO₂ programs.

Moreover, the following sections explain how manufacturers submit data and information to the agency. As part of the NPRM, NHTSA proposed to implement a new standardized template for manufacturers to use to submit CAFE data to the agency, as well as a standardized template for reporting credit transactions. Additionally, NHTSA proposed adding requirements that specify the precision of the fuel savings adjustment factor in 49 CFR 536.4. These new requirements are intended to streamline reporting and data collection from manufacturers, in addition to helping the agency use the best available data to inform CAFE program decision makers. The comments received to these proposals are included in Section ~~IX.C.2.a)(2)(d)~~~~IX.C.2.a)(2)(d)~~ along with NHTSA's responses to the comments and final resolutions to be established in the final rule.

NHTSA also sought comments on removing or modifying certain CAFE program flexibilities. The comments received and NHTSA's responses to those comments are discussed below.

a) How does NHTSA Determine Compliance?

(1) Manufacturers Submit Data to NHTSA and EPA and the Agencies Validate Results

EPCA, as amended by EISA, requires a manufacturer to submit reports to the Secretary of Transportation explaining whether the manufacturer will comply with an applicable CAFE standard for the model year for which the report is made; the actions a manufacturer has taken or intends to take to comply with the standard; and other information the Secretary requires by regulation.³⁰⁸⁶ A manufacturer must submit a report containing the above information during the 30-day period before the beginning of each model year, and during the 30-day period beginning the 180th day of the model year.³⁰⁸⁷ When a manufacturer determines it is unlikely to comply with a CAFE standard, the manufacturer must report additional actions it intends to take to comply and include a statement about whether those actions are sufficient to ensure compliance.³⁰⁸⁸

³⁰⁸⁶ 49 U.S.C. 32907(a).

³⁰⁸⁷ *Id.*

³⁰⁸⁸ *Id.*

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

To implement these reporting requirements, NHTSA issued 49 CFR Part 537, “Automotive Fuel Economy Reports,” which specifies three types of CAFE reports that manufacturers must submit. A manufacturer must first submit a pre-model year (PMY) report containing the manufacturer’s projected compliance information for that upcoming model year. By regulation, the PMY report must be submitted in December of the calendar year prior to the corresponding model year.³⁰⁸⁹ Manufacturers must then submit a mid-model year (MMY) report containing updated information from manufacturers based upon actual and projected information known midway through the model year. By regulation, the MMY report must be submitted by the end of July for the applicable model year.³⁰⁹⁰ Finally, manufacturers must submit a supplementary report to supplement or correct previously submitted information, as specified in NHTSA’s regulation.³⁰⁹¹

If a manufacturer wishes to request confidential treatment for a CAFE report, it must submit both a confidential and redacted version of the report to NHTSA. CAFE reports submitted to NHTSA contain estimated sales production information, which may be protected as confidential until the termination of the production period for that model year.³⁰⁹² NHTSA temporarily protects each manufacturer’s competitive sales production strategies, but does not permanently exclude sales production information from public disclosure. Sales production volumes are part of the information NHTSA routinely makes publicly available through the CAFE PIC.

The manufacturer reports provide information on light-duty automobiles such as projected and actual fuel economy standards, fuel economy performance values, and production volumes, as well as information on vehicle design features (e.g., engine displacement and transmission class) and other vehicle attribute characteristics (e.g., track width, wheelbase, and other off-road features for light trucks). Beginning with MY 2017, to obtain credit for fuel economy improvement values attributable to additional technologies, manufacturers must also provide information regarding A/C systems with improved efficiency, off-cycle technologies (e.g., stop-start systems, high-efficiency lighting, active engine warm-up), and full-size pickup trucks with hybrid technologies or with emissions/fuel economy performance that is better than footprint-based targets by specified amounts. This includes identifying the makes and model types equipped with each technology, the compliance category those vehicles belong to, and the associated fuel economy improvement value for each technology.³⁰⁹³ In some cases, NHTSA may require manufacturers to provide supplementary information to justify or explain the benefits of these technologies and their impact on fuel consumption or to evaluate the safety implication of the technologies. These details are necessary to facilitate NHTSA’s technical analyses and to ensure the agency can perform enforcement audits as appropriate.

³⁰⁹³ NHTSA collects model type information based upon the EPA definition for “model type” in 40 CFR 600.002.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NHTSA uses manufacturer-submitted PMY, MMY, and supplementary reports to assist in auditing manufacturer compliance data and identifying potential compliance issues as early as possible. Additionally, as part of its footprint validation program, NHTSA conducts vehicle testing throughout the model year to confirm the accuracy of the track width and wheelbase measurements submitted in the reports.³⁰⁹⁴ These tests help the agency better understand how manufacturers may adjust vehicle characteristics to change a vehicle's footprint measurement, and ultimately its fuel economy target. NHTSA also includes a summary of manufacturers' PMY and MMY data in an annual fuel economy performance report made publicly available on its PIC.

NHTSA uses EPA-verified final-model year (FMY) data to evaluate manufacturers' compliance with CAFE program requirements, and draws conclusions about the performance of the industry. After manufacturers submit their FMY data, EPA verifies the information, accounting for NHTSA and EPA testing, and subsequently forwards the final verified data to NHTSA.

(2) *Changes to CAFE Reporting Requirements Made by This Final Rule*

NHTSA proposed changes to its CAFE reporting requirements with the intent of streamlining data collection and reporting for manufacturers while helping the agency obtain the best available data to inform CAFE program decision-makers. The agency developed two new standardized reporting templates for manufacturers and proposed to start using the templates beginning in the 2019 compliance model year. In the NPRM, NHTSA sought comments on the templates. NHTSA's responses to the comments received and the changes to the templates for the final rule are presented below.

(a) *Standardized CAFE Reporting Template*

When NHTSA received and reviewed manufacturers' projection reports for MYs 2013 – 2015, the agency observed that most did not conform to the requirements specified in 49 CFR Part 537. For example, NHTSA identified several instances where manufacturers' CAFE reports included a "yes" or "no" response to a request for a vehicle's *numerical* ground clearance values. In a 2015 notice of proposed rulemaking, NHTSA proposed to amend 49 CFR Part 537 to require a new data format for manufacturers' light-duty vehicle CAFE projection reports.³⁰⁹⁵ In response to the proposal, some manufacturers commented that the previous changes in reporting requirements generated confusion and led to reporting errors. NHTSA recognized that the modification to the base tire definition in the 2012 final rule for MYs 2017 and later seemed to make some manufacturers uncertain about what footprint data was required in the reports.³⁰⁹⁶

³⁰⁹⁴ U.S. Department of Transportation, NHTSA, Laboratory Test Procedure for 49 CFR Part 537, Automobile Fuel Economy Attribute Measurements (Mar. 30, 2009), *available at* <http://www.nhtsa.gov/DOT/NHTSA/Vehicle%20Safety/Test%20Procedures/Associated%20Files/TP-537-01.pdf>.

³⁰⁹⁵ 80 FR 40540 (Jul. 13, 2015).

³⁰⁹⁶ 49 CFR 523.2.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Specifically, certain manufacturers did not understand that the modified base tire definition required them to provide estimated attribute-based target standards for each unique model type/footprint combination beginning with MY 2013. NHTSA discovered cases where manufacturers only provided target or vehicle data for certified vehicle configurations, and did not report information for each of the unique model type/footprint combinations for their available production vehicles in the market. However, NHTSA did not adopt the proposed data format from the 2015 proposed rule after receiving adverse comments from manufacturers.³⁰⁹⁷

Since the issuance of the final rule in 2016, NHTSA has continued to receive projection reports that contain inaccurate and/or missing data. These noncompliant reports impede NHTSA's ability to audit manufacturer compliance data, identify potential compliance issues, and analyze industry trends. Problems with inaccurate or missing data has become an even greater issue for manufacturers reporting on the new MY 2017 incentives for efficient A/C systems, off-cycle technologies, and full-size pickup trucks with hybrid technologies/improved exhaust emission performance.³⁰⁹⁸ These incentives are explained in Section IX.C.2.c)IX.C.2.e). Manufacturers seeking to take advantage of these new benefits must provide information at the model-type level; however, many manufacturers did not submit the required information in their PMY reports for MYs 2017, 2018, and 2019. This caused NHTSA's Office of Enforcement to send letters reminding manufacturers of their obligation to submit accurate and complete CAFE reports. NHTSA will continue to monitor the accuracy, completeness, and timeliness of manufacturers' CAFE reports and may take additional action as appropriate.

In the NPRM, NHTSA proposed a new standardized template for reporting PMY and MMY information, as specified in 49 CFR 537.7(b) and (c), as well as supplementary information required by 49 CFR 537.8. The template allows manufacturers to build out the required confidential versions of CAFE reports specified in 49 CFR Part 537 and to produce automatically the required non-confidential versions by clicking a button within the template. While NHTSA recognizes that modifications to the reporting requirements may initially be a slight inconvenience to manufacturers, the number of noncompliant reports the agency continues to receive justifies development of a uniform reporting method to help ensure compliance with CAFE regulations. Adopting a standardized template will assist manufacturers in providing the agency with all necessary data, thereby helping manufacturers to ensure they are complying with CAFE regulations. The template organizes the required data in a manner consistent with NHTSA and EPA regulations and simplifies the reporting process by incorporating standardized responses consistent with those provided to EPA. The template collects the relevant data, calculates intermediate and final values in accordance with EPA and NHTSA methodologies, and aggregates all the final values required by NHTSA regulations in a single summary worksheet. Thus, NHTSA believes that the standardized templates will benefit both the agency

³⁰⁹⁷ 81 FR 73958 (Oct. 25, 2016).

³⁰⁹⁸ NHTSA allows manufacturers to use these flexibilities and incentives for complying with standards starting in MY 2017.

and manufacturers by helping to avoid reporting errors, such as data omissions and miscalculations, and will ultimately simplify and streamline reporting.

NHTSA proposed to require that manufacturers use the standardized template for all PMY, MMY, and supplementary CAFE reports. NHTSA observed that a significant number of manufacturers submit their MMY reports as updated PMY reports—using the same amount of information, despite fewer data requirements. To conform with this method, NHTSA designed the template based on one standardized format that uses the same data requirements for all CAFE reports. This approach will further simplify CAFE projection reporting for manufacturers. The template contains a few additional data fields for certain vehicle characteristics; however, the inclusion of model type indexes will limit the number of required entries by populating a number of pre-entered data fields based on one value.

The standardized template will also allow NHTSA to modify its existing compliance database to accept and import uniform data and automatically aggregate manufacturers' data. This will allow NHTSA to execute its regulatory obligations more efficiently and effectively. Overall, the template will help to ensure compliance with data requirements under EPCA/EISA and drastically reduce the industry and government's burden for reporting in accordance with the Paperwork Reduction Act.³⁰⁹⁹ NHTSA made the template available through its docket as well as its PIC, and sought comment on the regulatory changes to the reporting process.

Comments on the template were received from the Auto Alliance, Global Automakers, Ford, Mercedes-Benz, Toyota, Volvo and Volkswagen. The Auto Alliance, Toyota, and Volkswagen opposed adopting the proposed template; however, Global Automakers agreed with the appropriateness of a standardized template that combines credit trading information with a data reporting template.³¹⁰⁰ Global Automakers also made two recommendations: (1) combine EPA's AB&T template with NHTSA's CAFE Projections Reporting Template to streamline reporting and reduce burden; and (2) add an FMY report requirement as an update to the MMY report submission.³¹⁰¹

Mercedes-Benz, Ford, and Volkswagen commented about data fields they believed were outdated, or not relevant to fuel economy testing or projecting fuel economy performance.³¹⁰² Mercedes-Benz stated that some required data fields are not currently collected as a part of the fuel economy testing process, and their capture would require additional burden.³¹⁰³ Mercedes-Benz believes those data fields should be an optional requirement. Additionally, Mercedes-Benz recommended that NHTSA omit certain data fields, and stated that it would be helpful if NHTSA

clarified its intention for the information in others.³¹⁰⁴ The specific data fields mentioned by Mercedes-Benz are in [Table IX-6](#). Ford stated that many of the data fields are outdated, have no bearing on compliance assessments, and are misaligned with the current reporting structure, which is dictated by model type index.³¹⁰⁵ Similarly, Volkswagen stated that the proposed reporting template is populated with many fields that do not immediately appear relevant to projecting CAFE performance, align with the existing requirements in 49 CFR 537.7, or seem relevant in the space of automotive technology.³¹⁰⁶

	Optional Equipment	

The Auto Alliance and Mercedes-Benz noted the differences in how NHTSA and EPA request data on A/C efficiency and off-cycle technologies. Mercedes-Benz highlighted the difficulty in predicting the projected sales production of the technologies, and the Auto Alliance cautioned that the number of reporting entries would increase by a factor of ten or more.³¹⁰⁷ The Auto Alliance stated its belief that the change in reporting requirements would cost its members more than \$1 million in information technology changes and that the changes could not be completed prior to MY 2021.³¹⁰⁸ Likewise, Ford contended that an implementation date for MY 2019 is aggressive and does not provide manufacturers with adequate lead time.³¹⁰⁹

³¹⁰⁹ Ford, Detailed Comments, NHTSA-2018-0067-11928.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The Auto Alliance emphasized that the templates lack common reporting standardization with submissions to EPA.³¹¹⁰ The Auto Alliance, Global Automakers, Toyota, and Volvo all requested that NHTSA and EPA accept a single, common reporting format to satisfy reporting for both agencies.³¹¹¹ Mercedes-Benz and Volkswagen requested stakeholder workshops to review the template with agency staff, with the former recommending that NHTSA host the workshops in partnership with EPA.³¹¹²

Ford requests that NHTSA re-examine the proposed required submission methods and reconsider current electronic submission methods.³¹¹³ Ford expressed concern about the efficiency and security issues involved in submitting data on a CD through the mail containing confidential business information.³¹¹⁴ Ford identified what it believes are better available avenues for submission, such as secured email or online portals like EPA's Central Data Exchange.³¹¹⁵

NHTSA disagrees with many of the manufacturers' assertions. Differences in EPA and NHTSA regulations prevent establishing a single reporting format for CAFE purposes. For example, EPA only needs early model year information for manufacturers' applications for certification required under 40 CFR 86.1843-01. Manufacturers submit a single application with extensive details for each certified vehicle within a test group (i.e., the certified vehicle represents all the vehicles within the test group with similar technologies and performance characteristics). In comparison, NHTSA's required early model year information is far less detailed and is aggregated for model types and compliance categories. However, NHTSA and EPA already share all the relevant CAFE FMY information pursuant to an interagency agreement. This arrangement not only benefits manufacturers but also reduces the burden on the Federal government. Since much of the required data in NHTSA's projections template is already contained in EPA final reports, manufacturers would not be required to generate additional information but simply to provide estimates along the way to finalizing the data. NHTSA plans to release a data matrix that maps data elements between the template and the EPA final reports. NHTSA will notify the public when the matrix will be available on its website. Consequently, there is no need to create an additional final report as an updated version of NHTSA's MMY report, as suggested by Global Automakers. Once NHTSA configures its CAFE database to accept the reporting template via file upload, the agency will be able to use the model type index data field to connect data values from the template to corresponding values in EPA's final report. Manufacturers should note that CAFE reports are estimated projections of

³¹¹⁰ Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³¹¹⁴ Ford, Detailed Comments, NHTSA-2018-0067-11928.

³¹¹⁵ Ford, Detailed Comments, NHTSA-2018-0067-11928.

the EPA final compliance data. Contrary to Mercedes concerns about the difficulty in predicting the projected sales production of the technologies, NHTSA only expects manufacturers to provide the most up-to-date information available 30 days before a report is required to be submitted to the Administrator as specified in 49 CFR Part 537.5(d). While manufacturer PMY reports may be limited in certain instances (excluding vehicles already in sales distribution), the MMY reports should be more inclusive and closer to the final values reported to EPA. Manufacturers should also be submitting supplementary reports to NHTSA if they believe there will be significant differences between CAFE MMY reports and the EPA final reports.

Commenters also stated that the A/C and off-cycle information reported in the NHTSA template is inconsistent with the EPA VERIFY.³¹¹⁶ NHTSA notes that the inconsistency between the agencies is intentional and necessary. NHTSA's off-cycle and A/C information must be collected in greater detail than that reported to the EPA VERIFY. NHTSA collects detailed information on A/C and off-cycle technologies for determining penetration rates of specific technologies in the market, as well as analyzing the types of technologies as equipped on specific model types. In comparison, EPA aggregates the data for calculating credits, which allows for combining the benefits for all the technologies equipped on a model type. NHTSA also will use the detailed information for public disclosure and for auditing purposes. However, NHTSA acknowledges the Auto Alliance's concerns about the burden placed on the industry for providing more detailed data and therefore will not require manufacturers to start using the templates for reporting until MY 2023. NHTSA also agrees with Ford that it is important to consider the issues of security and efficiency with respect to the submission of confidential information to the agency, and the agency will consider possible changes to its procedures relating to the receipt and handling of confidential information to ensure streamlined, secure, and efficient submission of confidential information, including CAFE reports.³¹¹⁷

Secondly, NHTSA agrees with Mercedes-Benz and Volkswagen that workshops will aid in implementing the templates by providing instruction on how to complete them. NHTSA plans to host a workshop for manufacturers to discuss the implementation process. NHTSA believes finalizing the template in this rulemaking is important to address continuing concerns with reporting noncompliance (i.e., missing, incomplete, or inaccurate submissions) with the existing provisions in Part 537. Ultimately, establishing the new templates and holding educational workshops will be more effective in achieving industry compliance than imposing penalties on a case-by-case basis for failure to comply with reporting provisions.

Finally, NHTSA is also adopting changes to the proposed template in response to comments from Mercedes-Benz, Ford, and Volkswagen. NHTSA made changes to several of the data fields discussed by Mercedes-Benz. NHTSA does not agree with Mercedes-Benz's recommendation to omit the "Type of Overdrive" or "Type of Torque Converter" data fields; however, the agency does believe the proposed data to be inserted into those fields may be too specific for CAFE purposes. Therefore, the agency is finalizing a requirement that

³¹¹⁶ See, e.g., Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³¹¹⁷ See 49 CFR part 512, 537.5.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturers identify whether vehicles are equipped with overdrive or a torque converter by selecting “Yes” or “No” from a dropdown list. The agency has also changed the “Calibration” field to “Other Calibration” to clarify the data being requested, and changed the “Auxiliary Emission Control Device” in the “Fuel Economy” worksheets to a dropdown that allows users to select multiple emission control systems. NHTSA believes that adding dropdown lists in the template creates uniformity in the reported information and makes the information more relevant to current vehicles.

The agency agrees with the essence of Volkswagen’s assertion that some of the required data fields may no longer be as common on contemporary vehicles, and therefore, may not apply to all manufacturers. As suggested by Mercedes-Benz, NHTSA has decided to make the “Catalyst Usage,” “Distributor Calibration,” “Choke Calibration,” and “Other Calibration” data fields optional with a default value of “N/A.” NHTSA does not agree with Mercedes-Benz’s recommendation that NHTSA provide a better understanding of its intention for the information in certain data fields. “Electric Traction Motor, Motor Controller,” “Battery Configuration,” “Electrical Charging System,” and “Energy Storage Device” are the data fields that characterize the basic powerplant for electric vehicles. Basic Engine, along with Carline and Transmission Class, make up a model type for light-duty vehicles. Therefore, those five fields are used to group vehicles by model type in accordance with EPA regulations. Fuel economy performance is calculated by Subconfiguration, which is a subset of a model type. As such, those five data fields are an integral part of grouping vehicles for fuel economy testing purposes in accordance with EPA regulations. NHTSA also does not agree with Volkswagen’s assertion that the template is populated with many fields that do not appear relevant to projecting CAFE performance. As previously mentioned, many of the data fields are used to arrange vehicles into groups for calculating fuel economy performance in accordance with 49 CFR 537.7.

Furthermore, NHTSA has re-engineered the template in a few areas to include additional supporting data elements used in calculating other data fields required by Part 537. These fields may not directly align with the existing requirements in Part 537 but are necessary for validation purposes. For this reason, NHTSA is also finalizing its proposal in the NPRM to remove the optional provisions for reporting the data fields for determining the CAFE model type target standards, making the information mandatory in the template. Additional changes have been made to the template to improve fuel economy calculations. NHTSA edited the template to include the calculation procedure for alternative-fuel vehicles and corrected the test procedure adjustment (TPA) calculation to align the fleet average fuel economy calculation methodology with 40 CFR 600.510-12. Several expanded worksheets and functional features were also added to the template to improve the usability of the templates for manufacturers. These changes include modifications such as adding the estimated credits and a minimum domestic passenger shortfall calculator as the last fields to the “Summary” worksheet. Other functional changes include protecting users from changing the formatting or data validation in each cell and allowing columns to be widened by users.

(b) *Standardized Credit Documents*

A credit “[t]rade” is defined in 49 CFR 536.3 as “the receipt by NHTSA of an instruction from a credit holder to place its credits in the account of another credit holder.”³¹¹⁸ “Traded credits are moved from one credit holder to the recipient credit holder within the same compliance category for which the credits were originally earned. If a credit has been traded to another credit holder and is subsequently traded back to the originating manufacturer, it will be deemed not to have been traded for compliance purposes.”³¹¹⁹ NHTSA does not administer trade negotiations between manufacturers and when a trade document is received the agreement must be issued jointly by the current credit holder and the receiving party.³¹²⁰ NHTSA does not settle contractual or payment issues between trading manufacturers.

NHTSA created its CAFE database to maintain credit accounts for manufacturers and to track all credit transactions. A credit account consists of a balance of credits in each compliance category and vintage held by the holder. While maintaining accurate credit records is essential, it has become a challenging task for the agency given the recent increase in credit transactions. Manufacturers have requested that NHTSA approve trade or transfer requests not only in response to end-of-model year shortfalls, but also, during the model year, when purchasing credits to bank.

To reduce the burden on all parties, encourage compliance, and facilitate quicker NHTSA credit transaction approval, the agency proposed in the NPRM to add a required template to standardize the information parties submit to NHTSA in reporting a credit transaction. Presently, manufacturers are inconsistent in submitting the information required by 49 CFR 536.8, creating difficulty for NHTSA in processing transactions. The template NHTSA proposed is a simple spreadsheet that trading parties fill out. When completed, parties will be able to click a button on the spreadsheet to generate a credit transaction summary and if applicable credit trade confirmation, the latter of which shall be signed by both trading entities. The credit trade confirmation serves as an acknowledgement that the parties have agreed to trade credits. The completed credit trade summary and a PDF copy of the signed trade confirmation must be submitted to NHTSA. Using the template simplifies CAFE compliance aspects of the credit trading process, and helps to ensure that trading parties follow the requirements for a credit transaction in 49 CFR 536.8(a).³¹²¹

Additionally, the credit trade confirmation includes an acknowledgement of the “error or fraud” provisions in 49 CFR 536.8(f)-(g), and the finality provision of 49 CFR 536.8(g). NHTSA sought comment on this approach, as well as on any changes to the template that may be necessary to facilitate manufacturer credit transaction requests. The agency uploaded the

³¹¹⁸ 49 CFR 536.3(b).

³¹¹⁹ *Id.*

³¹²⁰ *See* 49 CFR 536.8(a).

³¹²¹ Submitting a properly completed template and accompanying transaction letter will satisfy the trading requirements in 49 CFR part 536.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

proposed template to the NHTSA's docket and the CAFE PIC site for manufacturers to download and review.

Only Global Automakers commented on the proposed credit transaction template, and Global Automakers supported adopting a uniform template. Global Automakers stated that, in theory, it agrees that a standardized template with credit trading information is appropriate, and a similar template is already in use for these types of reporting requirements by its members that could be integrated into the end of the year EPA final report. Global Automakers believes the use of similar templates have been well-established, and such a template could be implemented across multiple agencies (i.e. NHTSA and EPA) with very little lag time in learning.³¹²² No comments were received on the transaction letter generated by the template.

For the final rule, NHTSA is finalizing the proposed requirements for its credit templates to be incorporated into provisions for Part 536. NHTSA understands that manufacturers may be using similar credit reporting templates as part of their current business processes but has decided to adopt the template proposed in the NPRM. The NHTSA credit templates are an integral part of a long-range technology deployment that is already underway and will automate the NHTSA's CAFE database and web portal systems. When complete, the systems and portals will receive information directly from manufacturers and enable manufacturers, independently, to confirm credit trades and receive real-time credit balances. For this reason, diverging from the proposed templates for the final rule would impose unnecessary costs upon NHTSA. In the interest of accommodating the transition by manufacturers from other standardized templates, the agency will delay mandatory use of the CAFE credit template until January 1, 2021. Manufacturers may deviate from the generated language in the NHTSA credit trade confirmation by adding additional qualifications but, at a minimum, must include the core information generated by the template.

(c) *Credit Transaction Information*

Credit trading among entities commenced in the CAFE program starting in MY 2011.³¹²³ To date, NHTSA has received numerous credit trades from manufacturers but has only made limited information publicly available.³¹²⁴ As discussed earlier, NHTSA maintains an online CAFE database with manufacturer and fleetwide compliance information that includes year-by-year accounting of credit balances for each credit holder. While NHTSA maintains this database, the agency's regulations currently state that it does not publish information on individual transactions, and NHTSA has not previously required trading entities to submit information regarding the compensation (whether financial, or other items of value)

³¹²² Global Automakers, Detailed Comments, NHTSA-2018-0067-12032.

³¹²³ 49 CFR 536.6(c).

³¹²⁴ Manufacturers may generate credits, but non-manufacturers may also hold or trade credits. Thus, the word "entities" is used to refer to those that may be a party to a credit transaction.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturers receive in exchange for credits.^{3125, 3126} Thus, NHTSA's PIC offers sparse information to those looking to determine the value of a credit.

The lack of information regarding credit transactions means entities wishing to trade credits have little, if any, information to determine the value of the credits they seek to buy or sell. It is widely assumed that the civil penalty for noncompliance with CAFE standards largely determines the upper value of a credit, because it is logical to assume that manufacturers would not purchase credits if it cost less to pay civil penalties instead, but it is unknown how other factors affect the value. For example, a credit nearing the end of its five-model-year lifespan would theoretically be worth less than a credit within its full five-model-year lifespan. In the latter case, the credit holder would likely value the credit more, as it can be used for compliance purposes for a longer period of time.

In the interest of facilitating a transparent and efficient credit trading market, NHTSA stated in the NPRM that consideration is being given to modifying its regulations for credit trade information. NHTSA sought comment in the NPRM about the feasibility of requiring more information disclosure around trades, including price information, noting that neither the public, shareholders, competitors, nor even the agencies themselves know the price of credit transactions. More specifically, the agencies proposed requiring trading parties to submit information disclosing the identities of the parties to credit trades, the number of credits traded, and the amount of compensation exchanged for credits. Furthermore, NHTSA proposed that regulations would also permit the agency to publish information about specific transactions on the PIC.

NHTSA received comments from Volkswagen, Honda, Fiat Chrysler, Toyota, Global Automakers, the Auto Alliance, UCS, and from one private citizen, Mr. Jason Schwartz, regarding the scope of available credit information. All auto associations and manufacturers requested that NHTSA maintain the confidentiality of credit trades and transactions. The remaining commenters felt increased transparency would benefit the market.

Global Automakers, the Auto Alliance, Fiat Chrysler, and Volkswagen stated that credit trades are business-to-business, contain internal information and can involve both financial and non-financial compensation between parties.³¹²⁷ They stated credit transactions should be viewed as being similar to other competitive purchase agreements, which include non-disclosure terms and strict confidentiality with regard to cost and compensation.³¹²⁸ They contended that

³¹²⁵ 49 CFR 536.5(e)(1).

³¹²⁶ NHTSA understands that not all credits are exchanged for monetary compensation. The proposal that NHTSA is adopting in this final rule requires entities to report compensation exchanged for credits, and is not limited to reporting monetary compensation.

³¹²⁸ See, e.g., Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

negotiations must remain confidential to protect the sensitive business practices for both the buyer and seller, and that revealing purchasing terms could result in a competitive disadvantage for both.³¹²⁹ Further, it was stated that certain transactions may not happen if they are publicized for fear of public criticism, making the program less efficient.³¹³⁰

Honda added that disclosing trading terms may not be as simple as a spot purchase at a given price.³¹³¹ Honda explained that it has undertaken a number of transactions for both CAFE and CO₂ credits, and there has been a range of complexity in these transactions due to numerous factors that are reflective of the marketplace, such as the volume of credits, compliance category, credit expiration date, a seller's compliance strategy, and even the CAFE penalty rate in effect at that time.³¹³² In addition, Honda stated that automakers have a range of partnerships and cooperative agreements with their own competitors.³¹³³ Honda commented that credit transactions can be an offshoot of these broader relationships, and difficult to price separately and independently.³¹³⁴ Thus, Honda believes there may not be a reasonable, or even meaningful, presentation of "market" information in a transaction "price."³¹³⁵ Finally, Honda concluded by stating that information on pricing terms and business partner pairings is highly competitive and, if made public, could divulge to competitors a buyer's and/or seller's future compliance strategy.³¹³⁶ For these reasons, Honda believes it is appropriate to maintain the confidentiality of trade terms, pricing information, and of trading partner identification.³¹³⁷

Fiat Chrysler stated that revealing credit transaction information would reveal highly confidential business information.³¹³⁸ It stated that credit transaction information may reveal the technology that is most valued by a company and the value of putting certain technology into a vehicle.³¹³⁹ It believed that credit trades are complex business transactions made at arm's length.³¹⁴⁰ As such, they may include monetary and non-monetary compensation, non-disclosure provisions, and other sensitive terms.³¹⁴¹ Fiat Chrysler commented that publicizing such sensitive information could stifle the credit market and potentially result in uncompetitive outcomes, and could also decrease the efficiency in the credit trading marketplace.³¹⁴² Fiat Chrysler further stated that the NPRM's justifications for requiring the disclosure of credit

transaction information is unfounded and the government has no need of this information in the regular course of doing business.³¹⁴³

The Auto Alliance, Honda, Toyota, and Volkswagen argued against NHTSA publishing credit movements each model year on its PIC. They stated that detailed credit banks by account holder are available to the public or entities wishing to engage in the credit market and that information is already sufficient.³¹⁴⁴ Global Automakers further contended that the agencies know which companies are trading and how those credits are being used, which is all that should be required for administering the program.³¹⁴⁵ The Auto Alliance argued that in private markets, trades and prices often are not made public; this privacy does not mean that the markets operate any less effectively, nor that the public at large does not benefit from the transactions that lower costs for all parties.³¹⁴⁶

Volkswagen further commented that revealing confidential purchase terms has no precedent in the automotive industry. Volkswagen's position is that it does not disclose contract pricing for purchasing fuel saving technologies from suppliers, such as for turbochargers or battery packs. Therefore, Volkswagen does not believe it is appropriate to disclose the purchase price for CAFE credits.³¹⁴⁷

Opposite views from those expressed by automobile manufacturers were received in the comments from UCS and Jason Schwartz. Both commenters strongly supported an increase in information regarding credit trading in the CAFE program.³¹⁴⁸ They argued that more information will allow manufacturers to make better informed decisions and lead to greater industry efficiency in general.³¹⁴⁹ UCS added that while the PIC does have some information, it is difficult to discern how the manufacturers are dividing credits to offset shortfalls.³¹⁵⁰ It requested NHTSA disclose at least as much information as EPA provides from its program, if not providing more information on transaction price and compliance category.³¹⁵¹ Jason Schwartz had similar arguments for more transparency. Mr. Schwartz added that the agencies can assume that credits may be traded at prices similar to the civil penalty rate for noncompliance under the CAFE standards, but not knowing the actual prices greatly complicates the agencies' estimations of the costs of complying with the standards.³¹⁵² Schwartz used several

³¹⁵² Jason Schwartz, Detailed Comments, NHTSA-2018-0067-12162.

examples to explain and justify the need for making data on credit transactions, prices, and holdings publicly available to help the agency and the public assess the efficacy of the program.³¹⁵³ He also explained that such information will enable the smooth operation of the credit market by enabling credit buyers to better evaluate the value of credits and placing all players on equal informational footing which facilitates price discovery, and assists buyers and sellers in reaching terms.³¹⁵⁴ He added that regulators should require greater transparency to facilitate oversight.³¹⁵⁵ He asserted his belief that greater transparency in tracking transactions and credits helps regulators detect fraud, manipulation, market power, abuse, and to enforce compliance.³¹⁵⁶

In response to these comments, NHTSA has decided not to share detailed information on credit transactions or the cost of individual credit transactions with the public. NHTSA agrees with manufacturers that revealing confidential purchase terms could result in a competitive disadvantage for both credit buyers and sellers, as well as harm to companies revealing highly confidential business materials. However, NHTSA believes that greater government oversight is needed over the CAFE credit market. NHTSA needs to understand more information surrounding trades, including costing information. As Honda recognized in its comments, NHTSA needs to understand the full range of complexity in transactions, monetary and non-monetary, in addition to the range of partnerships and cooperative agreements between credit account holders—which may impact the price of credit trades.³¹⁵⁷ NHTSA also believes, as mentioned by commenters, that disclosure of information concerning credit trades is important for facilitating government oversight for protecting against fraud, manipulation, market power, and abuse which may occur in the credit market.

NHTSA is adopting new reporting provisions in this final rule. Starting January 1, 2021, manufacturers will be required to submit all credit trade contracts, including costing and transactional information, to the agency. This information may be submitted confidentially, in accordance with 49 CFR part 512.³¹⁵⁸ NHTSA will use this information to determine the true cost of compliance for all manufacturers. This information will allow NHTSA to assess better the impact of its regulations on the industry, and provide more insightful information to use in developing future rulemakings. This confidential information will be held by secure electronic means in NHTSA's database systems. As for public information, NHTSA will include more information on the PIC on aggregated credit transactions, such as the combined flexibilities all manufacturers used for compliance as shown in [Figure IX-6](#)~~Figure IX-6~~, or information comparable to the credit information EPA makes available to the public. In the future, NHTSA will consider what information, if any, can be meaningfully shared with the public on credit

transactional details or costs, while accounting for the concerns raised by the automotive industry.

(d) *Precision of the CAFE Credit Adjustment Factor*

EPCA, as amended by EISA, required the Secretary of Transportation to establish an adjustment factor to ensure total oil savings are preserved when manufacturers trade credits.³¹⁵⁹ The adjustment factor applies to credits traded between manufacturers and to credits transferred across a manufacturer's compliance fleets.

In establishing the adjustment factor, NHTSA did not specify the exact precision of the output of the equation in 49 CFR 536.4(b). NHTSA's standard practice has been round to the nearest four decimal places (e.g., 0.0001) for the adjustment factor. However, in the absence of a regulatory requirement, many manufacturers have contacted NHTSA for guidance, and NHTSA has had to correct several credit transaction requests. In some instances, manufacturers have had to revise signed credit trade documents and submit additional trade agreements to properly address credit shortfalls.

NHTSA proposed in the NPRM to add requirements to 49 CFR 536.4 specifying the precision of the adjustment factor by rounding to four decimal places (e.g., 0.0001). NHTSA has also included equations for the adjustment factor in its proposed credit transaction report template, mentioned above, with the same level of precision. NHTSA sought comment on this approach but received no comments, and therefore is finalizing this approach in this final rule.

(3) *NHTSA Then Analyzes EPA-Certified CAFE Values for Compliance*

After manufacturers complete certification testing and submit their final compliance values to EPA, EPA verifies the data and issues final CAFE reports to manufacturers and NHTSA. NHTSA then evaluates whether the manufacturers' compliance categories (i.e., domestic passenger car, imported passenger car, and light truck fleets) meet the applicable CAFE standards. NHTSA uses EPA-verified data to compare fleet average standards with actual fleet performance values in each compliance category. Each vehicle a manufacturer produces has a fuel economy target based on its footprint (footprint curves are discussed above in Section II.C), and each compliance category has a CAFE standard measured in miles per gallon (mpg). The manufacturer's fleet average CAFE standard is calculated based on the fuel economy target value and production volume of each vehicle model. The CAFE performance is calculated based on the compliance value and production volume of each vehicle model. A manufacturer complies with the CAFE standard if its fleet average performance is greater than or equal to its required standard, or if it is able to use available compliance flexibilities, described below in Section ~~IX.C.2~~~~IX.C.2.c.~~ to resolve any shortfall.

³¹⁵⁹ 49 U.S.C. 32903(f)(1).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

If the average fuel economy level of the vehicles in a compliance category falls below the applicable fuel economy standard, NHTSA provides written notification to the manufacturer that it has not met that standard. The manufacturer is then required to confirm the shortfall and either submit a plan indicating how it will allocate existing credits, or if it does not have sufficient credits available in that fleet, how it will earn, transfer, and/or acquire credits, or pay the appropriate civil penalty. The manufacturer must submit a credit allocation plan or payment within 60 days of receiving agency notification.

NHTSA approves a credit allocation plan unless it finds the proposed credits are unavailable or that it is unlikely that the plan will result in the manufacturer earning sufficient credits to offset the projected shortfall. If a plan is approved, NHTSA revises the manufacturer's credit account accordingly. If a plan is rejected, NHTSA notifies the manufacturer and requests a revised plan or payment of the appropriate civil penalty. Similarly, if the manufacturer is delinquent in submitting a response within 60 days, NHTSA takes action to collect a civil penalty. If NHTSA receives and approves a manufacturer's plan to carryback future earned credits within the following three years in order to comply with current regulatory obligations, NHTSA will defer levying civil penalties for noncompliance until the date(s) when the manufacturer's approved plan indicates that the credits will be earned or acquired to achieve compliance. If the manufacturer fails to acquire or earn sufficient credits by the plan dates, NHTSA will initiate noncompliance proceedings to collect civil penalties.³¹⁶⁰

(4) *Civil Penalties for Noncompliance*

In the event that a manufacturer does not comply with a CAFE standard, EPCA provides that the manufacturer is potentially liable for a civil penalty.³¹⁶¹ The manufacturer determines whether to use available credits to reduce or offset its potential penalty.³¹⁶² This penalty rate is \$5.50 for each tenth of a mpg that a manufacturer's average fuel economy falls short of the standard for a given model year multiplied by the total volume of those vehicles in the affected compliance category manufactured for that model year.³¹⁶³ A person (or manufacturer) that violates 49 U.S.C. 32911(a), including general CAFE violations other than those for failing to comply with CAFE standards (i.e., fuel economy labeling violations), is also liable to the United States Government for a civil penalty of not more than \$42,530 for each violation. A separate violation occurs for each day the violation continues. All penalties are paid to the U.S. Treasury and not to NHTSA.³¹⁶⁴

³¹⁶⁰ See generally 49 CFR part 536.

³¹⁶¹ 49 U.S.C. 32911-12.

³¹⁶² See 49 U.S.C. 32912.

³¹⁶³ NHTSA finalized a retaining the \$5.50 civil penalty rate in an April 2018 NPRM. See 83 FR 13904 (Apr. 2, 2018).

³¹⁶⁴ 49 USC 32912(e) allows for fiscal year 2008 and each fiscal year thereafter, the total amount deposited in the general fund of the Treasury during the preceding fiscal year from fines, penalties, and other funds obtained through enforcement actions conducted pursuant to EISA and EPCA (including funds obtained under consent decrees), the Secretary of the Treasury, subject to the availability of appropriations, shall: (1) transfer 50 percent of such total

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Potential Civil Penalty

$$= \$5.50 \times (\text{Avg. FE Performance} - \text{Avg. FE Standard}) \times 10 \\ \times \text{Total Production}$$

Since the inception of the CAFE program, the U.S. Treasury has collected a total of \$1,049,355,116 in CAFE civil penalty payments. Generally, import manufacturers have paid significantly more in civil penalties than domestic manufacturers, with the majority of payments made by import manufacturers for passenger cars and not light trucks. Over the total program lifetime, import manufacturers paid a total of \$1,048,896,676 in CAFE penalties while domestic manufacturers paid a total of \$458,440.³¹⁶⁵

Prior to the CAFE credit trade and transfer program, several manufacturers opted to pay civil penalties instead of complying with CAFE standards. Since NHTSA introduced trading and transferring, manufacturers have largely traded or transferred credits to achieve compliance, rather than paying civil penalties for noncompliance. NHTSA therefore assumes that buying and selling credits is a more cost-effective strategy for manufacturers than paying civil penalties, in part, because it seems logical that the price of a credit is directly related to the civil penalty rate and decreases as a credit's life diminishes.³¹⁶⁶ Prior to trading and transferring, on average, manufacturers paid \$28,073,281.93 in civil penalty payments annually (a total of \$814,125,176 from MYs 1982 to 2010). Since trading and transferring began, manufacturers now pay an average of \$26,136,660 each model year. The agency notes that six manufacturers have paid civil penalties since 2011 totaling \$235,229,940; Fiat Chrysler paid a civil penalty in MY 2016 equal to \$77,268,720.50 and in MY 2017 equal to \$79,376,643.50 for failing to meet the minimum domestic passenger car standards for those MYs. NHTSA expects that, over the next several years, manufacturers will face challenges in avoiding paying further civil penalties as standards increase in stringency.

b) What Exemptions and Exclusions does NHTSA Allow?

(1) Emergency and Law Enforcement Vehicles

Under EPCA, manufacturers are allowed to exclude emergency vehicles, which include law enforcement vehicles, from their CAFE fleet.³¹⁶⁷ All manufacturers that produce emergency

amount to the account providing appropriations to the Secretary of Transportation for the administration of this chapter, which shall be used by the Secretary to support rulemaking under this chapter; and (2) transfer 50 percent of such total amount to the account providing appropriations to the Secretary of Transportation for the administration of this chapter, which shall be used by the Secretary to carry out a program to make grants to manufacturers for retooling, reequipping, or expanding existing manufacturing facilities in the United States to produce advanced technology vehicles and components.

³¹⁶⁵ These totals include penalties associated with all fleets for these manufacturers. For example, the total penalties paid by import manufacturers includes penalties associated with shortfalls in those manufacturers' domestic passenger car fleets.

³¹⁶⁶ See 49 CFR 536.4 for NHTSA's regulations regarding CAFE credits.

³¹⁶⁷ 49 U.S.C. 32902(e).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

vehicles have historically done so. NHTSA did not propose any changes to this exclusion and therefore is retaining the provision without change for the final rule.

(2) *Small Volume Manufacturers*

Per 49 U.S.C. 32902(d), NHTSA established requirements for exempted small volume manufacturers in 49 CFR part 525, “Exemptions from Average Fuel Economy Standards.” The small volume manufacturer exemption is available for any manufacturer whose projected or actual combined sales (whether in the U.S. or not) are fewer than 10,000 passenger automobiles in the model year two years before the model year for which the manufacturer seeks an exemption.³¹⁶⁸ The manufacturer must submit a petition with information stating that the applicable CAFE standard is more stringent than the maximum feasible average fuel economy level that the manufacturer can achieve.³¹⁶⁹ NHTSA must then issue by *Federal Register* notice, a proposed decision granting or denying the petition and inviting public comment.³¹⁷⁰ If the agency proposed to grant the petition, the notice includes an alternative average fuel economy standard for the passenger automobiles manufactured by the manufacturer.³¹⁷¹ After conclusion of the public comment period, the agency publishes a final decision in the *Federal Register*.³¹⁷² If the agency grants the petition, it establishes an alternative standard, which is the maximum feasible average fuel economy level for the manufacturers to which the alternative standard applies.³¹⁷³ NHTSA did not propose and is not making any changes to the small volume manufacturer provision or alternative standards regulations in this rulemaking.

c) *What Compliance Flexibilities and Incentives are Currently Available Under the CAFE Program and How do Manufacturers Use Them?*

There are several compliance flexibilities and incentives that manufacturers can use to achieve compliance with CAFE standards beyond applying fuel economy-improving technologies. Some compliance flexibilities and incentives are statutorily mandated by Congress through EPCA and EISA. These specifically include program credits generated from overcompliance, including the ability to carry-forward, carryback, trade and transfer credits, and special fuel economy calculations for dual- and alternative-fueled vehicles (discussed in turn, below). However, 49 U.S.C. 32902(h) expressly prohibits NHTSA from considering the availability of statutorily established credits (either for building dual- or alternative-fueled vehicles or from accumulated transfers or traders) in setting the level of the standards. Thus, NHTSA may not raise CAFE standards because manufacturers have enough credits to meet higher standards, or because alternative fuel vehicles (including electric vehicles) are available to

³¹⁶⁸ 49 CFR 525.5.

³¹⁶⁹ 49 CFR 525.7(h).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

help manufacturers achieve compliance. This is an important difference from EPA's authority under the CAA, which does not contain such a restriction, and which flexibility EPA has utilized in the past in determining appropriate levels of stringency for its program.

Generating, trading, transferring, and applying CAFE credits is governed by statute.³¹⁷⁴ Program credits are generated when a vehicle manufacturer's fleet over-complies with its standard for a given model year, meaning its vehicle fleet achieved a higher corporate average fuel economy value than the amount required by the CAFE program for that fleet in that model year. Conversely, if the fleet average CAFE level does not meet the standard, the fleet would incur debits (also referred to as a shortfall). A manufacturer whose fleet generates a credit shortfall in a given model year can resolve its shortfall using any one or combination of several credits flexibilities, including credit carryback, credit carry-forward, credit transfers, and credit trades.

NHTSA also has promulgated compliance flexibilities and incentives consistent with EPCA's provisions regarding calculation of fuel economy levels for individual vehicles and for fleets.³¹⁷⁵ These compliance flexibilities and incentives, which were first adopted in the 2012 rule for MYs 2017 and later, include A/C efficiency improvement and off-cycle adjustments, and adjustments for advanced technologies in full-size pickup trucks, including adjustments for mild and strong hybrid electric full-size pickup trucks and performance-based incentives in full-size pickup trucks. The fuel consumption improvement benefits of these technologies measured by various testing methods can be used by manufacturers to increase the CAFE performance of their fleets.

Under NHTSA regulations, credit holders (including, but not limited to manufacturers) have credit accounts with NHTSA where they can, as outlined above, hold credits, and use them to achieve compliance with CAFE standards, by carrying forward, carrying back, or transferring credits across compliance categories. Manufacturers with excess credits in their accounts can also trade credits to other manufacturers, who may use those credits to resolve a shortfall currently or in a future model year. A credit may also be cancelled before its expiration date if the credit holder so chooses. Traded and transferred credits are subject to an "adjustment factor" to ensure total oil savings are preserved.³¹⁷⁶ Credits earned before MY 2011 may not be traded or transferred.³¹⁷⁷

Credit "carryback" means that manufacturers are able to use credits to offset a deficit that had accrued in a prior model year, while credit "carry-forward" means that manufacturers can bank credits and use them towards compliance in future model years. EPCA, as amended by EISA allows manufacturers to carryback credits for up to three model years, and to carry-

³¹⁷⁷ 49 CFR 536.6(c).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

forward credits for up to five model years.³¹⁷⁸ Credits expire the model year after which the credits may no longer be used to achieve compliance with fuel economy regulations.³¹⁷⁹ Manufacturers seeking to use carryback credits must have an approved carryback plan from NHTSA demonstrating their ability to earn sufficient credits in future MYs that can be carried back to resolve the current MY's credit shortfall. EPA also follows these same limitations under its CO₂ program.³¹⁸⁰

Credit "trading" refers to the ability of manufacturers or persons to sell credits to, or purchase credits from, one another. EISA gave NHTSA discretion to establish by regulation a CAFE credit trading program, to allow credits to be traded between vehicle manufacturers, now codified at 49 CFR part 536.³¹⁸¹ EISA prohibited manufacturers from using traded credits to meet the minimum domestic passenger car CAFE standard.³¹⁸²

As mentioned previously, the agencies sought comments in the NPRM on whether and how each agency's existing flexibilities and incentives might be amended, revised, or deleted to avoid the inefficiencies and market distortions as discussed earlier. NHTSA was concerned with the potential for unintended consequences. Specifically, comments were sought on the appropriate level of compliance flexibilities, including credit trading, in a program that is correctly designed to follow statutory direction to create maximum feasible fuel economy standards. Given that the credit trading program is discretionary under EISA, NHTSA also sought comments on whether the credit trading provisions in 49 CFR part 536 should cease to apply beginning in MY 2022. Comments were sought on whether to allow all incentive-based adjustments, except those that are mandated by statute, to expire, in addition to other possible simplifications to reduce market distortion, improve program transparency and accountability, and improve overall performance of the compliance programs.

The comments received from the public and NHTSA's responses to those comments are discussed below. A summary of all the flexibilities and incentives, and information on whether they were either retained or modified for the final rule, is presented in

³¹⁷⁹ 49 CFR 536.3(b).

³¹⁸⁰ As part of its MYs 2017-2025 GHG program final rulemaking, EPA did allow a one-time CO₂ carry-forward beyond five years, such that any credits generated from MYs 2010 through 2016 will be able to be used to comply with light-duty vehicle GHG standards at any time through MY 2021.

³¹⁸¹ 49 U.S.C. 32903(f).

³¹⁸² 49 U.S.C. 32903(f)(2).

Table IX-1~~Table IX-1~~ through Table IX-4~~Table IX-4~~.

(1) *Credit Carry-Forward and Back*

Under the CAFE program, when the average fuel economy of a compliance fleet manufactured in a particular model year exceeds its applicable average fuel economy standard, the manufacturer earns credits.³¹⁸³ The credits may be applied to: (1) any of the 3 consecutive model years immediately before the model year for which the credits are earned; and (2) any of the 5 consecutive model years immediately after the model year for which the credits are earned. For example, a credit earned for exceeding model year 2017 standards will be usable for compliance purposes through and including the 2022 compliance model year. NHTSA sought no comments or proposed changes to any of the aspects of its lifespan for CAFE credits because of the existing statutory limitation set forth by Congress. The public offered no comments on such flexibilities.

(2) *Credit Trading*

All commenters responding to the NPRM on this issue favored retaining the existing CAFE credit trading program. Comments on credit trading were received from Volkswagen, Honda, General Motors, CARB, BorgWarner, Jaguar Land Rover, Fiat Chrysler, Global Automakers, the Auto Alliance, the Institute for Policy Integrity, Toyota, and academic commenters, Jeremy Michalek and Jason Schwartz. No comments were received supporting the idea of changing the existing credit trading program.

In general, manufacturers' comments centered around problems in predicting whether consumers will purchase the fuel efficient vehicles necessary for manufacturers to meet their compliance obligations. They stated that continuing the credit trading program allows manufacturers to address uncertainty in the market better.³¹⁸⁴ The Auto Alliance, Volkswagen, Fiat Chrysler, and Honda commented that credit flexibilities allow manufacturers to comply with the program even when faced with market uncertainties.³¹⁸⁵ Honda stated that credit trading allows the government to set reasonable standards without fear of having to cater to the least-capable manufacturer.³¹⁸⁶ Jaguar Land Rover stated the removal of NHTSA's credit trading programs would increase and intensify the dis-harmonization between the CO₂ and CAFE programs.³¹⁸⁷

Global Automakers, Fiat Chrysler, Jason Schwartz, and Jeremy Michalek each commented that the credit trading program allows for a more efficient compliance process given

³¹⁸³ 49 U.S.C. 32903 and 49 CFR 536.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

that more fuel-efficient manufacturers can sell their credits to manufacturers who fall short.³¹⁸⁸ These commenters and BorgWarner stated that the program lowers the overall cost of reducing fuel consumption.³¹⁸⁹ Likewise, Jaguar Land Rover, Fiat Chrysler, and General Motors argued compliance flexibilities, like trading, increase the ability to achieve higher fuel economy and reduced CO₂ emissions. They found that the credit trading flexibility allows them to invest more money in technologies that will lead to future increases in their fuel economy.³¹⁹⁰ Similarly, CARB argued credit flexibilities have been shown to be successful in reducing emissions and spurring innovation. It saw no reason to remove a successful program.³¹⁹¹

Fiat Chrysler stated that credit trading allows manufacturers to provide more choices for consumers since manufacturers are not required to meet the standard exactly, but rather, they can purchase traded credits and then provide vehicles the public is demanding while still complying with fleet average standards.³¹⁹² They stated that this leads to the overall compliance of the U.S. fleet while allowing for more consumer choices. They further added that if the program is removed, manufacturers that currently generate credits from their fuel-efficient fleet may find it more profitable to begin producing less fuel-efficient vehicles, perhaps even halting the current improvements in fuel efficiency across the industry.³¹⁹³

Honda commented that regulatory flexibilities, such as credit trading, built into the CO₂ and CAFE programs have become critical elements to the programs' success, especially in the face of product cadences with uneven sales that do not always match compliance obligations.³¹⁹⁴ General Motors stated its belief that program flexibilities will continue to play an increasingly important role in reducing CO₂ emissions and increasing fuel economy through technologies and innovations.³¹⁹⁵ CARB stated that existing flexibilities create consistency in compliance planning for automakers for model years in the existing program.³¹⁹⁶ Fiat Chrysler added that each of the CAFE and CO₂ programmatic tools and flexibilities should be retained, improved and strengthened. Fiat Chrysler opined that this is a chance for the agencies to make better policies that work more efficiently and as intended, and cautioned that eliminating them now could have the serious negative impact of making the standards more stringent and costlier for manufacturers.³¹⁹⁷

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NHTSA is not making changes to its credit trading provisions in the final rule. NHTSA sought comments on removing the optional credit trading program to explore public views on market distortions or windfalls that occur as a result of the credit trading program. However, commenters consistently opined that removing existing flexibilities might result in manufacturers not building certain types of vehicles. This could adversely impact compliance plans over multiple model years. NHTSA concurs with those views, and since this final rule adopts CAFE standards that continuously increase through MY 2026, understands the importance of allowing for credit trading to provide additional means of achieving compliance for manufacturers who face varying degrees of difficulty in achieving the standards the agencies are finalizing today. With increasing standards, credit trading flexibilities help to compensate for an uneven sales mix of vehicle types and to aid with compliance planning. EPA final sales volumes, as presented earlier, show a shift in consumers purchasing more small SUVs subject to passenger car standards, and these vehicles are less fuel efficient than the compact and mid-sized passenger cars that previously dominated the market. The need to ensure consumer choice is adequately considered drives the need for the agency to provide credit trading flexibility to manufacturers. For example, even with increasing standards, a manufacturer could continue to sell certain types of vehicles with lower mpg performance over a longer period of time to satisfy its consumers by purchasing credits or carrying credits back from future model years to address the mpg fleet shortages caused by these vehicles, before ultimately having to introduce more fuel-efficient technologies. NHTSA believes that these types of scenarios are consistent with the purpose of the CAFE credit program, as adopted by Congress.

(3) *Credits Transferring*

Credit “transfer” means the ability of manufacturers to move credits from their passenger car fleet to their light truck fleet, or vice versa. As part of the EISA amendments to EPCA, NHTSA was required to establish by regulation a CAFE credit transferring program, now codified at 49 CFR part 536, to allow a manufacturer to transfer credits between its car and truck fleets to achieve compliance with the standards.³¹⁹⁸ For example, credits earned by overcompliance with a manufacturer’s car fleet average standard may be used to offset debits incurred because of that manufacturer’s failed to meet the truck fleet average standard in a given year. However, EISA imposed a cap on the amount by which a manufacturer could raise its CAFE performance through transferred credits: 1 mpg for MYs 2011-2013; 1.5 mpg for MYs 2014-2017; and 2 mpg for MYs 2018 and beyond.³¹⁹⁹ These statutory limits will continue to apply to the determination of compliance with CAFE standards. EISA also prohibits the use of transferred credits to meet the minimum domestic passenger car fleet CAFE standard.³²⁰⁰

In the NPRM, NHTSA responded to the 2016 petition for rulemaking from the Auto Alliance and Global Automakers (Alliance/Global or Petitioners) asking to amend the regulatory

³¹⁹⁸ See 49 U.S.C. 32903(g)(1).

³¹⁹⁹ 49 U.S.C. 32903(g)(3).

³²⁰⁰ 49 U.S.C. 32903(g)(4).

definition of “transfer” as it pertains to compliance flexibilities.³²⁰¹ In particular, Alliance/Global requested that NHTSA add text to the definition of “transfer” stating that the statutory transfer cap in 49 U.S.C. 32903(g)(3) applies when the credits are transferred. Alliance/Global assert that adding this text to the definition is consistent with NHTSA’s prior position on this issue in the MYs 2012-2016 final rule, in which NHTSA stated:

*NHTSA interprets EISA not to prohibit the banking of transferred credits for use in later model years. Thus, NHTSA believes that the language of EISA may be read to allow manufacturers to transfer credits from one fleet that has an excess number of credits, within the limits specified, to another fleet that may also have excess credits instead of transferring only to a fleet that has a credit shortfall. This would mean that a manufacturer could transfer a certain number of credits each year and bank them, and then the credits could be carried forward or back ‘without limit’ later if and when a shortfall ever occurred in that same fleet.*³²⁰²

NHTSA clarified in the NPRM, based upon a previous interpretation, that the transfer cap from EISA does not limit how many credits may be *transferred* in a given model year, but it does limit the *application* of transferred credits to a compliance category in a model year.³²⁰³ The interpretation concludes by stating that, “Thus, manufacturers may transfer as many credits into a compliance category as they wish, but transferred credits may not increase a manufacturer’s CAFE level beyond the statutory limits.”³²⁰⁴

NHTSA maintains its views that the transfer caps in 49 U.S.C. 32903(g)(3) are properly read to apply to the application of credits. As NHTSA explained in the NPRM, it understands that the language in the MYs 2012-2016 final rule could be read to suggest that the transfer cap applies at the time credits are transferred. However, NHTSA believes its existing interpretation — that the transfer cap applies at the time the credits are used — is a more appropriate, plain language reading of the statute. While manufacturers have approached NHTSA with various interpretations that would essentially allow them to circumvent the EISA transfer cap, NHTSA believes such interpretations are improper because they would not give effect to the statutory transfer cap. Therefore, NHTSA proposed in the NPRM to deny Alliance/Global’s petition to revise the definition of “transfer” in 49 CFR 536.3, and is now finalizing that denial.

³²⁰¹ Auto Alliance and Global Automakers Petition for Direct Final Rule with Regard to Various Aspects of the Corporate Average Fuel Economy Program and the Greenhouse Gas Program (June 20, 2016) at 13, available at https://www.epa.gov/sites/production/files/2016-09/documents/petition_to_epa_from_auto_alliance_and_global_automakers.pdf [hereinafter Alliance/Global Petition].

³²⁰⁴ *Id.*

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

In response to the tentative denial of the petition above in the NPRM, comments were received from the Global Automakers and Toyota asking NHTSA to reconsider applying the transfer cap of 2.0 mpg per year when credits are transferred rather than when they are applied.³²⁰⁵ They reiterated that imposing the cap when applying the credits is overly burdensome, but did not provide any new information that has persuaded NHTSA to change its view that the petition should be denied. The Auto Alliance also stated that NHTSA should revise its definition of “transfer” to be more consistent with EPA.³²⁰⁶

Other more general comments to the NPRM were also received from Walter Kreucher, Jeremy Michalek, Global Automakers, the Auto Alliance, and Toyota, regarding the use of the credit transfer flexibility. These commenters generally appreciated the transfer flexibility for its ability to reduce compliance costs.³²⁰⁷ More specifically, Walter Kreucher commented that the ability to transfer credits between compliance categories was beneficial for manufacturers and allowed for efficiency in the markets and reduce compliance costs.³²⁰⁸

For the final rule, NHTSA is not making any changes to the existing provisions regarding transferring credits. NHTSA’s position remains unchanged that the transfer cap in 49 U.S.C. 32903(g)(1) clearly limits the amount of performance increase for a manufacturer’s fleet that fails to achieve the prescribed standards. The same statutory provision prevents NHTSA from changing its definition for transfer to be consistent with EPA. Consequently, NHTSA is not changing its definition or its previous interpretation that the application of transfer caps applies at the time the credits are used and not when transferred. Therefore, NHTSA is finalizing its decision to deny the Auto Alliance and Global Automakers petition.

(4) *Minimum Domestic Passenger Car Standard*

EPCA, as amended by EISA, addresses the minimum domestic passenger car standard (MDPCS), clearly stating that any manufacturer’s domestically-manufactured passenger car fleet must meet the greater of either 27.5 mpg on average, or 92 percent of the average fuel economy projected by the Secretary for the combined domestic and non-domestic passenger automobile fleets manufactured for sale in the U.S. by all manufacturers in the model year, which projection shall be published in the Federal Register when the standard for that model year is promulgated in accordance with 49 U.S.C. 32902(b).³²⁰⁹ Since that requirement was added to the statute, the “92 percent” has always been greater than 27.5 mpg. NHTSA published the 92 percent MDPCS for MYs 2017–2025 at 49 CFR 531.5(d) as part of the 2012 final rule. 49 CFR 531.5(e) explains that the published MDPCS for MYs 2022–2025 are not final and may change when NHTSA sets standards for those model years. This is consistent with the statutory requirement that the 92

³²⁰⁵ Global Automakers, Detailed Comments, NHTSA-2018-0067-12032; Toyota, Detailed Comments, NHTSA-2018-0067-12150.

³²⁰⁹ 49 U.S.C. 32902(b)(4).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

percent standards must be determined at the time an overall passenger car standard is promulgated and published in the Federal Register.³²¹⁰ Any time NHTSA establishes or changes a passenger car standard for a model year, the MDPCS for that model year must also be evaluated or re-evaluated and established accordingly. Thus, this final rule establishes the applicable MDPCS for MYs 2021-2026.

The 2016 Alliance/Global petition for rulemaking asked NHTSA to retroactively revise the 92 percent MDPCS for MYs 2012–2016 “to reflect 92 percent of the required average passenger car standard taking into account the fleet mix as it actually occurred, rather than what was forecast.” The petitioners claimed that doing so would be “fully consistent with the statute.”³²¹¹ NHTSA acknowledged in the NPRM that determining the 92 percent value ahead of the model year to which it applies, based on the information then available to the agency, results in a different mpg number than if NHTSA determined the 92 percent value based on the information available at the end of the model year in question. NHTSA further acknowledged that determining the 92 percent value in advance can make the MDPCS more stringent than it could be if it were determined at the end of the model year, if manufacturers end up producing more larger-footprint passenger cars than NHTSA originally anticipated.

Accordingly, NHTSA sought comments in the NPRM on the request made by Alliance/Global recognizing the uncertainty inherent in projecting specific mpg values far into the future. NHTSA also stated that it is possible to define the mpg values associated with a CAFE standard (i.e., the footprint curve) as a range rather than as a single number. If NHTSA took that approach, 92 percent of that “standard” would also, necessarily, be a range.

NHTSA received several comments regarding the minimum domestic passenger car standard (MDPCS). Commenters included Walter Kreucher, a joint submission from the States of California et al. and the Cities of Oakland et al., Fiat Chrysler, and the Auto Alliance. Walter Kreucher asserted that NHTSA must continue to allow and even expand flexibilities to allow manufacturers to meet the MDPCS. He suggested applying retroactive air conditioning credits to help manufacturers become compliant.³²¹² Fiat Chrysler and the Auto Alliance requested NHTSA establish a MDPCS range rather than a single value and then recalculate that range to a value at the end of each model year. This will lead to a more accurate MDPCS value, which they believe are currently set too high.³²¹³ The joint submission from the States of California et al. and the Cities of Oakland et al. did not believe the minimum domestic passenger car standard needed revising. They stated EPCA does not allow for an interpretation of a range and a projected minimum set value was how the statute was written.³²¹⁴

[Text Forthcoming]

(5) *Fuel Savings Adjustment Factor*

Under NHTSA's credit trading regulations, a fuel savings adjustment factor is applied when trading occurs between manufacturers or when a manufacturer transfers credits between its fleets, but not when a manufacturer carries credits forward or carries back credits within the same fleet.³²¹⁵ The Alliance/Global requested in their 2016 petition that NHTSA require manufacturers to apply the fuel savings adjustment factor when credits are carried forward or carried back within the same fleet, including for existing, unused credits.

Per EISA, total oil savings must be preserved in NHTSA's credit trading program.³²¹⁶ The statutory provisions for credit transferring within a manufacturer's fleet do not explicitly include the same requirement; however, NHTSA prescribed a fuel savings adjustment factor that applies to both credit trades between manufacturers and credit transfers between a manufacturer's compliance fleets.^{3217, 3218}

When NHTSA initially considered the preservation of oil savings, the agency explained how one credit is not necessarily equal to another. For example, the fuel savings lost if the average fuel economy of a manufacturer falls one-tenth of an mpg below the level of a relatively low standard are greater than the average fuel savings gained by raising the average fuel economy of a manufacturer one-tenth of a mpg above the level of a relatively high CAFE standard.³²¹⁹ The effect of applying the adjustment factor is to increase the numerical value of credits for compliance accounting that are earned for exceeding a CAFE standard, that are applied to a compliance category with a higher CAFE standard. Likewise, the adjustment factor has the effect of decreasing the numerical value of credits for compliance accounting that are earned for exceeding a CAFE standard, that are applied to a compliance category with a lower CAFE standard. While applying the adjustment factor impacts the compliance accounting value of credits which are denominated in miles per gallon, the adjustment maintains the real world value of credits from the perspective of the actual amount of fuel consumed or saved.

³²¹⁵ See 49 CFR 536.4(c).

³²¹⁶ 49 U.S.C. 32903(f)(1).

³²¹⁷ 49 U.S.C. 32903(g).

³²¹⁸ See 49 CFR 536.5; see also 74 FR 14430 (Mar. 30, 2009) (Per NHTSA's final rule for MY 2011 Average Fuel Economy Standards for Passenger Cars and Light Trucks, "There is no other clear expression of congressional intent in the text of the statute suggesting that NHTSA would have authority to adjust transferred credits, even in the interest of preserving oil savings. However, the goal of the CAFE program is energy conservation; ultimately, the U.S. would reap a greater benefit from ensuring that fuel oil savings are preserved for both trades and transfers. Furthermore, accounting for traded credits differently than for transferred credits does add unnecessary burden on program enforcement. Thus, NHTSA will adjust credits both when they are traded and when they are transferred so that no loss in fuel savings occurs.").

³²¹⁹ 74 FR 14432 (Mar. 30, 2009).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Alliance/Global stated, in its 2016 petition, that while carry-forward and carryback credits have been used for many years, the CAFE standards did not change during the Congressional CAFE freeze, meaning credits earned during those years were associated with the same amount of fuel savings from year to year.³²²⁰ Alliance/Global suggest that because there is no longer a Congressional CAFE freeze, NHTSA should apply the adjustment factor when moving credits within a manufacturer's fleet (i.e. carry-forward or carryback) beginning retroactively in MY 2011.³²²¹

In the NPRM, NHTSA tentatively denied Alliance/Global's request to apply the fuel savings adjustment factor to credits that are carried forward or carried back within the same fleet to the extent that the request would impact credits carried forward or back retroactively within manufacturers' compliance fleets (i.e., credits that were generated prior to MY 2021 when the standards set by this rule first apply). NHTSA tentatively determined that applying the adjustment factor to credits earned in prior model years would be inequitable to apply retroactively. There would be an advantage for manufacturers carrying credits into future model years with higher CAFE standards. Manufacturers have historically planned compliance strategies based, at least in part, on the existing rules for how credits could be carried forward and back, including the lack of an adjustment factor when credits are carried forward or back within the same fleet. Thus, retroactively requiring an adjustment factor could disadvantage certain manufacturers without credits, and result in windfalls for other manufacturers.

To explore the impact on future model years, NHTSA sought additional comments in the NPRM on the feasibility of applying the fuel savings adjustment factor to credits carried forwards or back starting in MY 2021. Global Automakers submitted new comments arguing that the application of fuel savings adjustment factors to credits carried forward or back would not result in a credit windfall. They believed this practice would ensure that credits have a consistent value over time.³²²²

Comments from Global Automakers provided no further justification that would persuade NHTSA to consider changing its position on denying the application of the adjustment factor to carry-forward and carryback credits beginning with MY 2011. NHTSA continues to be concerned about the inequitable outcome retroactive adjustments would have on the credit market. Therefore, NHTSA is finalizing its decision to deny the Alliance/Global request to apply the adjustment factor to credits carried forward or carried back within a compliance category retroactively beginning as early as MY 2011.

Congress expressly required that DOT establish a credit "transferring" regulation, to allow individual manufacturers to move credits from one of their fleets to another (e.g., using a credit earned for exceeding the light truck standard for compliance with the domestic passenger car standard). Congress also gave DOT discretion to establish a credit "trading" regulation so

³²²⁰ Alliance/Global Petition at 10.

³²²¹ Alliance/Global Petition at 4.

³²²² Global Automakers, Detailed Comments, NHTSA-2018-0067-12032.

that credits may be bought and sold between manufacturers.³²²³ Congress specified that trading was for earned credits “to be sold to manufacturers whose automobiles fail to achieve the prescribed standards such that the total oil savings associated with manufacturers that exceed the prescribed standards are preserved.”³²²⁴ NHTSA established 49 CFR part 536 believing it was consistent with the statute for transferred credits to be subject to the same “adjustment factor” to ensure total oil savings are preserved.³²²⁵ NHTSA believed that no further application of the adjustment factor to other credit flexibilities would be appropriate at that time. NHTSA sought comments in the NPRM to explore the consequences associated with applying the adjustment factor to credits carried forward and back starting in MY 2021, but no further insight was gained from the comments received. Therefore, NHTSA is retaining its existing requirements for the adjustment factor to be applied to transferred and traded credits only. NHTSA will continue considering potential application of the adjustment factor for all types of credit flexibilities in the future, and may consider regulatory changes in subsequent rulemakings.

(6) *VMT Estimates for Fuel Savings Adjustment Factor*

NHTSA uses the vehicle miles traveled (VMT) estimate as part of its fuel savings adjustment equation to ensure that when traded or transferred credits are used, fuel economy credits are adjusted to ensure fuel oil savings is preserved.³²²⁶ For MYs 2017-2025, NHTSA finalized VMT values of 195,264 miles for passenger car credits, and 225,865 miles for light truck credits.³²²⁷ These VMT estimates harmonized with those used in EPA’s CO₂ program. For MYs 2011-2016, NHTSA estimated different VMTs by model year.

In the NPRM, NHTSA explained that Alliance/Global requested in their 2016 petition that NHTSA apply fixed VMT estimates to the fuel savings adjustment factor for MYs 2011-2016 similar to how NHTSA handled VMT values for MYs 2017-2025.³²²⁸ NHTSA rejected a similar request from the Auto Alliance in the MY 2017 and later rulemaking, citing lack of scope, and expressing concern about the potential loss of fuel savings.³²²⁹

The Alliance/Global argued that data from MYs 2011-2016 demonstrate that no fuel savings would have been lost, as was NHTSA’s concern.³²³⁰ Alliance/Global asserted that by not revising the MY 2012-2016 VMT estimates, credits earned during that timeframe were

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

undervalued.³²³¹ Therefore, Alliance/Global argued that NHTSA should retroactively revise its VMT estimates to “reflect better the real-world fuel economy results.”³²³²

Such retroactive adjustments could have unfair adverse effects upon manufacturers for decisions they made based on the regulations as they existed at the time. As Alliance/Global acknowledged, adjusting VMT estimates would disproportionately affect manufacturers that have a credit deficit and were part of EPA’s Temporary Lead-time Allowance Alternative Standards (TLAAS).³²³³ The TLAAS program sunsets for MYs 2021 and later. Given that some manufacturers would be disproportionately affected were NHTSA to adopt Alliance/Global’s proposal, in the NPRM, NHTSA tentatively denied Alliance/Global’s request to change the agency’s VMT schedules for MYs 2011-2016 retroactively. Alliance/Global’s suggestion that a TLAAS manufacturer should be allowed to elect either approach does not change the fact that manufacturers in the TLAAS program made production decisions based on the regulations as understood at the time.³²³⁴ NHTSA sought comments on the Alliance/Global requests in the NPRM.

However, no further comments were received on this issue in response to the NPRM. Therefore, NHTSA is finalizing its decision to deny the Alliance/Global request to modify the VMT schedules for MYs 2011-2016.

(7) *Special Fuel Economy Calculations for Dual and Alternative Fueled Vehicles*

As discussed at length in prior rulemakings, EPCA, as amended by EISA, encouraged manufacturers to build alternative-fueled and dual- (or flexible-) fueled vehicles by providing special fuel economy calculations for “dedicated” (that is, 100 percent) alternative fueled vehicles and “dual-fueled” (that is, capable of running on either the alternative fuel or gasoline/diesel) vehicles.

Dedicated alternative-fuel automobiles include electric, fuel cell, and compressed natural gas vehicles, among others. The statutory provisions for dedicated alternative fuel vehicles in 49 U.S.C. 32905(a) state that the fuel economy of any dedicated automobile manufactured after MY 1992 shall be measured “based on the fuel content of the alternative fuel used to operate the automobile. A gallon of liquid alternative fuel used to operate a dedicated automobile is deemed to contain 0.15 gallon of fuel.” Under EPCA, for dedicated alternative fuel vehicles, there are no limits or phase-out for this special fuel economy calculation, unlike for dual-fueled vehicles, as discussed below.

EPCA’s statutory incentive for dual-fueled vehicles at 49 U.S.C. 32906 and the measurement methodology for dual-fueled vehicles at 49 U.S.C. 32905(b) and (d) expire after

³²³¹ *Id.*

³²³² Alliance/Global Petition at 11.

³²³³ *Id.* at 11 n.12.

³²³⁴ *See id.* at 11-12 n.12.

MY 2019; therefore, NHTSA had to examine the future of these provisions in the MY 2017 and later CAFE rulemaking. NHTSA and EPA concluded that it would be inappropriate to measure dual-fueled vehicles' fuel economy like that of conventional gasoline vehicles with no recognition of their alternative fuel capability, which would be contrary to the intent of EPCA/EISA. The agencies determined that for MY 2020 and later vehicles, the general statutory provisions authorizing EPA to establish testing and calculation procedures provide discretion to set the CAFE calculation procedures for those vehicles. The methodology for EPA's approach is outlined in the 2012 final rule for MYs 2017 and later at 77 FR 63128 (Oct. 15, 2012). In the NPRM, NHTSA sought comments on that current approach.

NHTSA received comments from the Coalition for Renewable Natural Gas, NGV America, the American Gas Association, the American Public Gas Association, CARB, Ingevity Corporation, Fuel Freedom Foundation, UCS, National Farmers Union, Indiana Corn Growers Association, Volkswagen, and a joint submission from Ariel Corp. and VNG.co.

Fuel Freedom Foundation and the National Farmers Union asserted that the agencies should continue offering incentives for emerging technology vehicles including natural gas vehicles, internal combustion engine (ICE) vehicles that encourage renewable fuel use, electric and hydrogen fuel cell vehicles, flex-fuel vehicles (FFVs), and dedicated high-octane vehicles designed for compatibility with mid-level ethanol blends.³²³⁵

Indiana Corn Growers Association and Fuel Freedom Foundation specified that FFVs, as well as vehicles that run on mid-level ethanol blends, should receive credit for the petroleum reduction value.³²³⁶ For vehicles using higher-ethanol blends, these commenters stated that the agencies should establish more accurate petroleum equivalency factors for the proportion of ethanol versus gas.³²³⁷ Clean Fuels Development Coalition requested credits for producing "Engines Optimized for High-Octane" be reinstated.³²³⁸ Volkswagen made the same request and added that a pathway to higher-octane fuel is important to it.³²³⁹

Ariel Corp. and VNG.co, the Coalition for Renewable Natural Gas, NGV America, the American Gas Association, and the American Public Gas Association commented that the agencies should expand incentives for natural gas vehicles in the light-duty sector especially for pick-up trucks, work vans, and sport utility vehicles.³²⁴⁰ They argued that current incentives are

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

not strong enough to induce manufacturers to produce natural gas vehicles. They further requested that the market penetration rates be removed for light-duty trucks.³²⁴¹

The Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association argued that an AMFA factor of 0.15 is low and because some natural gas vehicles can operate at 100 percent natural gas, a higher fuel economy credit is justified. They further supported a permanent use of the 0.15 factor for dual-fuel vehicles.³²⁴² Similarly, Ingevity Corporation, and Ariel Corp. and VNG.co argued that natural gas vehicle emissions should return to the 0.15 divisor.³²⁴³

Ingevity Corporation, Ariel Corp. and VNG.co, the Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association requested that the agencies remove the minimum driving range requirement for natural gas vehicles. They stated a belief that a range twice that of electric vehicles holds NGVs to an unfairly higher standard.³²⁴⁴

CARB argued that flexibilities for natural gas vehicles and high-octane blend vehicles are not yet warranted.³²⁴⁵ Similarly, UCS argued that natural gas is a greenhouse gas and benefits from natural gas vehicles are undermined by their costs. UCS further commented that natural gas vehicle technology does not need any incentives since it has already been deployed and in the market.³²⁴⁶

In response to comments, NHTSA has determined that EPCA and EISA prescribe the incentive that is used for dedicated liquid and gaseous alternative fuel vehicles, and the CAFE program will continue to use those statutory incentives. For dedicated alternative fuel vehicles, the statute provides a significant incentive that only counts 15 percent of the actual energy used.³²⁴⁷ For dual fuel vehicles, NHTSA has determined that, for the portion of operation that occurs on an alternative fuel, it is consistent to use the same incentive that is specified by EPCA and EISA for dedicated fuel vehicles. For example, for the hypothetical case of a vehicle that operates 99 percent of the time on an alternative fuel, it would be appropriate for that vehicle to

³²⁴⁵ CARB, Detailed Comments, NHTSA-2018-0067-11873.

³²⁴⁶ UCS, Detailed Comments, NHTSA-2018-0067-12039.

³²⁴⁷ 32905(a) "... A gallon of a liquid alternative fuel used to operate a dedicated automobile is deemed to contain .15 gallon of fuel." 32905(c) "... One hundred cubic feet of natural gas is deemed to contain .823 gallon equivalent of natural gas. The Secretary of Transportation shall determine the appropriate gallon equivalent of other gaseous fuels. A gallon equivalent of gaseous fuel is deemed to have a fuel content of .15 gallon of fuel."

receive nearly the same incentive as a dedicated alternative fuel vehicle that operates 100 percent of the time on alternative fuel. Applying the same 15 percent of energy used incentive for both dedicated and dual fuel vehicles remains appropriate. NHTSA therefore is not adopting any new incentives for any alternative fueled vehicles.

D. Compliance Issues that Affect Both the CO₂ and CAFE Programs

Because the real world CO₂ emissions reduction benefits of certain technologies cannot be measured or fully measured using 2-cycle test procedures, EPA established new compliance flexibilities under its CAA authority, starting in MY 2012, that allow manufacturers credit for emission compliance for installing these technologies. Those flexibilities are designed to recognize improvements in A/C systems with greater efficiency and other technologies that reduce real world tailpipe CO₂ emissions. More specifically, real world improvements that cannot be measured on 2-cycle tests are determined and used to calculate additional CO₂ credits (Mg) for each model type that has the technologies. Because these tailpipe CO₂ improving technologies also impact fuel economy, NHTSA adopted the same flexibilities and incentives beginning in MY 2017. EPA and NHTSA also established incentives for both the CO₂ and CAFE programs that give added compliance credits and fuel consumption improvement values for the production of strong and mild hybrid full-size pickup trucks beginning in MY 2017.³²⁴⁸ Pursuant to 49 USC 32903, EPA adjusts manufacturers' CAFE performance values using the emissions benefits or incentives provided for these technologies. EPA developed a methodology for manufacturers to increase their passenger car and light truck fuel economy performance in accordance with procedures set forth by EPA in 40 CFR part 600. For the NHTSA CAFE program, the CO₂ reductions (in grams per mile) are converted to fuel consumption improved values (FCIVs, gallons per mile) and then the benefits are summed for all the model types in the manufacturer's fleets. The total FCIVs are used to adjust and increase manufacturers' CAFE (mpg) performance values.

It is important to note that while these flexibilities and incentives have similar value for compliance in the CAFE and CO₂ programs, there are differences in how they are accounted for in each of the programs due to differences in the structure of the programs. The CAFE program accounts for A/C efficiency and off-cycle improvements through EPA measurement procedures that determine *fuel consumption improvement values* (FCIVs). The CAFE A/C efficiency and off-cycle provisions do not involve manufacturer *credits*.³²⁴⁹ There are no bankable, tradable, or transferrable credits earned by a manufacturer for implementing more efficient A/C systems or installing an off-cycle technology. In fact, the only credits provided for in NHTSA's CAFE program are those earned by overcompliance with a standard.³²⁵⁰ As discussed above, EPA adjusts CAFE performance values based on use of these technologies. Specifically, off-cycle technologies and A/C efficiency improvements are used to adjust individual vehicle compliance values based on the fuel consumption improvement values of these technologies. For example, a

³²⁴⁸ See 40 CFR 86.1867-86.1868, 86.1870.

³²⁴⁹ This is not to be confused with EPA's parallel program, which refers to the GHG's consideration of A/C improvements and off-cycle technologies as "credits."

³²⁵⁰ 49 U.S.C. 32903.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturer's vehicle *as a whole* may exceed its fuel economy target through the inclusion of A/C efficiency and/or off-cycle technologies, and therefore is regarded as a credit-generating vehicle.

Illustrative of this confusion, in the 2016 Alliance/Global petition, the petitioners asked NHTSA to avoid imposing unnecessary restrictions on the use of credits. Alliance/Global referenced language from an EPA report that stated compliance is assessed by measuring the tailpipe emissions of a manufacturer's vehicles, and then reducing vehicle CO₂ compliance values depending on A/C efficiency improvements and off-cycle technologies.³²⁵¹ This language is consistent with NHTSA's statement in the MY 2017 and later final rule, which explained how the agencies coordinate and apply off-cycle and A/C adjustments. "There will be separate improvement values for each type of credit, calculated separately for cars and for trucks. These improvement values are subtracted from the manufacturer's 2-cycle-based fleet fuel consumption value to yield a final new fleet fuel consumption value, which would be inverted to determine a final fleet fuel CAFE value."³²⁵²

In the NPRM, NHTSA proposed to deny Alliance/Global's request because what the petitioners refer to as "technology credits" are actually FCIVs applied to the fuel economy performance of individual vehicles.³²⁵³ Thus, these adjustments are not actually "credits," per the usage of "credit" in EPCA/EISA and are not subject to the "carry-forward" and "carryback" provisions in 49 U.S.C. 32903. To alleviate confusion, and to ensure consistency in nomenclature, NHTSA proposed to update language in its regulations to reflect that the use of the term "credits" to refer to A/C efficiency and off-cycle technology adjustments should actually be termed fuel consumption improvement values (FCIVs). No further comments were received on this issue in response to the NPRM. For the final rule, NHTSA is finalizing the proposed changes in its regulations to remove the term "credits" and to replace it with the term "adjustments" for the FCIV benefit for A/C and off-cycle technologies.

Manufacturers seeking to use these flexibilities and incentives start the process each model year by submitting information to EPA and seeking any necessary approvals, as appropriate. The use of certain technologies only requires submitting information to EPA, whereas others require a formal request process for approval. The differences are explained in the following sections. The compliance information manufacturers must submit to EPA describes the technologies, the flexibilities or incentives being used, and the testing approach for deriving benefits. Initial information is required as a part of the EPA certification process, as specified by 40 CFR 86.1843-01 in advance of each model year. For technologies requiring approvals, EPA must confirm the manufacturer's testing approach, receive test results to assess the benefit of the technology, and then issue a *Federal Register* notice that invites public comment. EPA review and determination usually occurs before the end of the compliance model

³²⁵¹ See Alliance/Global Petition at 15.

³²⁵² 77 FR 62726 (Oct. 15, 2012).

³²⁵³ The agencies also refer to A/C and off-cycle technology improvement values as "credits" sporadically throughout their regulations. NHTSA is amending its regulations to reflect these are adjustments and not actual credits that can be carried forward or back. For a further discussion, see above.

year, if manufacturers provide information to EPA on a timely basis. To receive the benefit under the CAFE program for technologies that require approvals, manufacturers must concurrently submit to NHTSA the same information that is sent to EPA. EPA consults with NHTSA in reviewing A/C efficiency and off-cycle adjustments to fuel economy performance values that require approval. NHTSA provides EPA its assessment of the suitability of a technology considering: (1) whether the technology has a direct impact upon improving fuel economy performance; (2) whether the technology is related to crash-avoidance technologies, safety critical systems or systems affecting safety-critical functions, or technologies designed for the purpose of reducing the frequency of vehicle crashes; (3) information from any assessments conducted by EPA related to the application, the technology, and/or related technologies; and (4) any other relevant factors.

EPA and NHTSA sought comments on several aspects of the shared flexibilities and incentives in the NPRM. Presented in the following sections is a summary of the comments received and the agencies final decisions for the final rule.

1. Incentives for Advanced Technologies in Full-Size Pickup Trucks

In the 2012 rulemaking for MYs 2017 and beyond, EPA and NHTSA finalized incentives for largescale implementation of hybrid electric full size pickup trucks for both the CO₂ and CAFE programs. CO₂ credits and CAFE FCIVs are available for manufacturers that produce full-size pickup trucks with Mild HEV or Strong HEV technology, provided the percentage of production with the technology is greater than specified percentages.³²⁵⁴ In addition, CO₂ credits and CAFE FCIVs are available for manufacturers that produce full-size pickups with other technologies that enables full size pickup trucks to exceed performance of their CO₂ or CAFE targets based on footprints by specified amounts.³²⁵⁵ These performance-based incentive created a technology neutral path to achieve the CO₂ credits and CAFE FCIVs, which would encourage the development and application of new technological approaches.

EPA and NHTSA established limits on the vehicles eligible to qualify for these incentives; a truck must meet minimum criteria for bed size and towing or payload capacity, and meet minimum production thresholds (in terms of a percentage of a manufacturer's full-size pickup truck fleet) in order to qualify for the incentives. Under the existing program, the strong hybrid credit is 20 grams/mile per vehicle, available through MY 2025, if installed on at least 10 percent of the manufacturer's full-size pickup truck fleet in the model year. The program also includes an incentive for mild hybrids of 10 grams/mile per vehicle during MYs 2017–2021. To be eligible the manufacturer would have to show that the mild hybrid technology is utilized in a specified portion of its truck fleet beginning with at least 20 percent of a company's full-size pickup production in MY 2017 and ramping up to at least 80 percent in MY 2021.³²⁵⁶

³²⁵⁴ 77 FR 62651 (Oct. 15, 2012).

³²⁵⁵ *Id.*

³²⁵⁶ 77 FR 62651-2 (Oct. 15, 2012).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

At present, no manufacturer has qualified to use the full-size pickup truck incentives. One vehicle manufacturer introduced a mild hybrid pickup truck for MY 2019 but failed to meet the minimum production threshold. Others have announced potential collaborations, or have already started production on future hybrid or electric models.³²⁵⁷ However, the agencies continue to be aware that there may not ever be sufficient consumer interest for these full-size pickup truck technologies to reach significant or qualifying volumes, as consumers may believe that they are less durable or provide reduced utility.

Prior to the NPRM, the agencies received input from automakers that these incentives should be extended and available to all light-duty trucks (e.g., cross-over vehicles, minivans, sport utility vehicles, and smaller-sized pickups) and not only full-size pickup trucks.³²⁵⁸ Automakers also recommended that the program's eligibility production thresholds should be removed because they discourage the application of technology since manufacturers cannot be confident of achieving the thresholds. Some stakeholders have also suggested an additional incentive for strong and mild hybrid passenger cars. In the proposal, the agencies sought comment on whether these incentives should be expanded along the lines suggested by stakeholders, on the basis that perhaps these incentives could lead to additional product offerings of strong hybrids, and technologies that offer similar emissions reductions, which could enable manufacturers to achieve additional long-term CO₂ emissions reductions. In addition, the agencies sought comment on whether to extend either the incentive for hybrid full-size pickup trucks or the performance-based incentive past the dates that EPA specified in the 2012 final rule for MY 2017 and later. The agencies also sought comment on eliminating all incentive programs, as discussed above.

The agencies received a variety of comments on the full-size pickup truck incentives. Comments were received from General Motors, Volkswagen, Honda, BorgWarner, Fiat Chrysler, Toyota, DENSO International, Ford, CARB, Global Automakers, UCS, Electric Drive Transportation Association, the Auto Alliance, Ariel Corp. and VNG.co, ACEEE, the Coalition for Renewable Natural Gas, NGV America, the American Gas Association, and the American Public Gas Association.

³²⁵⁷ Chrysler released the 2019 Dodge Ram 1500 "eTorque" (see <https://www.fueleconomy.gov/feg/Find.do?action=sbs&id=40736&id=40737&id=40394&id=40397>) which qualifies as a mild hybrid pickup truck by replacing the traditional alternator on the engine with a 48-volt Li-ion battery-powered, belt-driven motor generator that improves performance, efficiency, payload, towing capabilities and drivability. The production volume of these vehicles did not qualify for the full-size pickup truck electric/hybrid incentive for MY 2019. Other vehicle models are currently in research or in development for future years but uncertain to reach the required sales volumes to qualify for incentives. For example, *the hybrid and battery-electric versions of the F-150 pickup*, see <https://www.trucks.com/2019/09/18/ford-truck-engineer-explains-electric-f-150-pickup-plans> (September 18, 2019), or the new electric pickup truck manufactured by Rivian, <https://www.trucks.com/2019/04/24/ford-plans-new-electric-truck-rivian-invests-500-million/> (April 24, 2019); or the Tesla all electric pickup truck (<https://www.cnn.com/2019/11/08/success/tesla-pickup-reveal/index.html>) (November 8, 2019).

³²⁵⁸ 83 FR 43461 (Aug. 24, 2018).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The Auto Alliance, Toyota, General Motors, BorgWarner, Global Automakers, and Volkswagen advocated to expand the full-size pickup truck hybrid incentives to all hybrid vehicles.³²⁵⁹ They argued that prices for all hybrid-drive technologies are projected to remain high and consumer demand for these vehicles is still slow to increase.³²⁶⁰ They asserted that expanding the full-size pickup truck hybrid incentive to all hybrid vehicles will help encourage investments in hybrid technology and continue to help manufacturers address their compliance challenges.³²⁶¹ Similarly, these commenters reported that the current market, fueled by consumer demand for SUVs and lower than expected gas prices, is not conducive to consumer acceptance of or demand for electric vehicles.³²⁶² For these reasons, they stated their belief that it is important to support adjustments and expansion of the current incentives to promote hybrid technologies.

The Auto Alliance, DENSO International, Global Automakers, Fiat Chrysler, and Honda also argued for alternative pathways for the agencies to consider allowing the full-size pickup truck hybrid incentives to be expanded to the light-duty truck segment, but not to all passenger vehicles. They argued that hybrid technology has been slow to be applied in the light-duty truck segment, but has been broadly applied to passenger cars.³²⁶³

Toyota, Global Automakers, and the Auto Alliance suggested the incentives for light-duty trucks should amount to 20 grams/mile.³²⁶⁴ Global Automakers added that in addition to expanding full-size pickup truck hybrid incentives to light trucks, the agency should consider a smaller incentive for hybrid electric passenger vehicles as well.³²⁶⁵ The Auto Alliance and Toyota suggested a 10 grams/mile credit for passenger cars.³²⁶⁶ Volkswagen further requested the hybrid pickup credit to be expanded to all hybrid cars and trucks.³²⁶⁷

Toyota, the Auto Alliance, Electric Drive Transportation Association, Ford, DENSO International, Global Automakers, Fiat Chrysler, and BorgWarner commented that having minimum production percentages for hybrid pickup trucks discourages manufacturers from investing in hybrid technologies. They requested that the agencies consider eliminating the

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

percentage of production requirement and provide incentives in proportion to the value of the technology.³²⁶⁸ Ford stated that the minimum production percentages unfairly penalize larger manufacturers who must produce more pickup trucks to claim the incentives than a smaller volume manufacturer.³²⁶⁹

Ariel Corp. and VNG.co, the Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association commented the pickup truck incentives should be expanded to include natural gas vehicles.³²⁷⁰ They suggested a “Natural Gas Pickup” incentive like the hybrid-electric and performance-based pickup credits, but no minimum production requirement.³²⁷¹

ACEEE and UCS commented that hybrid technology has been around for quite a while and has been applied in every vehicle class. They discouraged the agencies from applying more incentives to these vehicles.³²⁷² Specifically, UCS stated that incentives for electric vehicles are mostly driven by state regulation, and EPA and NHTSA policies are rewarding manufacturers for meeting standards they were already required to meet.³²⁷³ UCS commented that hybrids are not innovators or game-changing vehicles—they are simply one of many strategies by which manufacturers can reduce emissions and should not receive special treatment.³²⁷⁴

CARB commented that incentives for full-size hybrid pickup trucks should remain limited in their scope and that increasing or expanding those incentives can erode emissions benefits.³²⁷⁵ CARB further commented that hybrid electric vehicles (HEVs) are widely available at varying levels of power and performance across vehicle sizes, and CARB does not believe HEVs deserve special treatment in the CO₂ vehicle regulations.

After carefully considering the comments received, EPA and NHTSA are not adopting any new or expanded incentives for hybrid vehicles or full-size pickup trucks. The agencies believe any new or expanded incentives would likely not result in any further emissions benefits or fuel economy improvements since an increase in sales volume would not be expected. The agencies agree with CARB and ACEEE, and UCS that hybrids are a well-established technology

that has already been applied to a wide range of vehicles and, as such, no further incentives are warranted at this time. Further, the agencies believe that incentivizing manufacturers to implement specific technologies is inappropriate, as manufacturer fuel economy performance should represent actual fuel consumption. The agencies believe any new or expanded incentives would likely not result in any further emissions benefits or fuel economy improvements beyond those measured during testing. Manufacturers did not provide sufficient evidence to support their position in a manner that leads the agencies to conclude otherwise.

2. Flexibilities for Air Conditioning Efficiency

A/C systems are virtually standard automotive accessories, and more than 95 percent of new cars and light trucks sold in the U.S. are equipped with mobile A/C systems. A/C system usage places a load on an engine, which results in additional tailpipe CO₂ emissions and fuel consumption; the high penetration rate of A/C systems throughout the light-duty vehicle fleet means that efficient systems can significantly impact the total energy consumed and CO₂ emissions. A/C systems also have non-CO₂ emissions associated with refrigerant leakage.³²⁷⁶ Manufacturers can improve the efficiency of A/C systems through redesigned and refined A/C system components and controls.³²⁷⁷ That said, such improvements are not measurable or recognized using 2-cycle test procedures, since A/C is turned off during 2-cycle testing. Any A/C system efficiency improvements that reduce load on the engine and improve fuel economy is therefore not measurable on those tests.

The CO₂ and CAFE programs include flexibilities to account for the real world CO₂ emissions and fuel economy improvements associated with improved A/C systems and to include the improvements for compliance.³²⁷⁸ The total of A/C efficiency credits is calculated by summing the individual credit values for each efficiency improving technology used on a vehicle, as specified in the A/C credit menu. The total A/C efficiency credit sum for each vehicle is capped at 5.0 grams/mile for cars and 7.2 grams/mile for trucks. Additionally, the off-cycle credit program contains credit earning opportunities for technologies that reduce the thermal loads on a vehicle from environmental conditions (solar loads or parked interior air temperature).³²⁷⁹ These technologies are listed on a thermal control menu that provides a

³²⁷⁶ See Section V for further details. Notably, manufacturers cannot claim CAFE-related benefits for reducing A/C leakage or switching to an A/C refrigerant with a lower global warming potential. While these improvements reduce GHG emissions consistent with the purpose of the CAA, they generally do not impact fuel economy and, thus, are not relevant to the CAFE program.

³²⁷⁷ The approach for recognizing potential A/C efficiency gains is to utilize, in most cases, existing vehicle technology/componentry, but with improved energy efficiency of the technology designs and operation. For example, most of the additional A/C-related load on an engine is because of the compressor, which pumps the refrigerant around the system loop. The less the compressor operates, the less load the compressor places on the engine resulting in less fuel consumption and CO₂ emissions. Thus, optimizing compressor operation with cabin demand using more sophisticated sensors, controls, and control strategies is one path to improving the efficiency of the A/C system. For further discussion of A/C efficiency technologies, see Section II.D of the NPRM and Chapter 6 of the accompanying PRIA.

³²⁷⁸ See 40 CFR 86.1868-12.

³²⁷⁹ See 40 CFR 86.1869-12(b).

predefined improvement value for each technology. If a vehicle has more than one thermal load improvement technology, the improvement values are added together, but subject to a cap of 3.0 grams/mile for cars and 4.3 grams/mile for trucks.

EPA requested comment on the A/C caps and on whether A/C efficiency technologies and off-cycle thermal control technologies should be combined under a single cap, since the technologies directly interact with each other. That is, improved thermal control results in reduced A/C loads for the more efficient A/C technologies. If the thermal credits were removed from the off-cycle menu, they would no longer be counted against the 10 grams/mile menu cap discussed above, representing a way to provide more room under the menu cap for other off-cycle technologies. Specifically, EPA sought comment on replacing the current off-cycle thermal efficiency capped value of 10 grams/mile, with separate caps of 8 grams/mile for cars and 11.5 grams/mile for trucks.

Comments concerning the A/C caps were received from the Auto Alliance, DENSO, Fiat Chrysler, and Volkswagen. DENSO commented that A/C efficiency credits earned through the off-cycle petition process should not count toward the A/C credit cap. If A/C credits granted through the off-cycle petition process are no longer counted toward the A/C credit cap, it stated that manufacturers would be significantly incentivized to develop new and innovative technologies.³²⁸⁰ Fiat Chrysler requested that certain A/C credits for electrical technologies (*i.e.*, A/C blower motor controls that limit wasted electrical energy) be transferred to the off-cycle credit list.³²⁸¹ Volkswagen further supported the removal of the thermal control technology credit caps and suggested that implementing caps at the fleet average level, rather than per-vehicle, could be less constraining.³²⁸² DENSO pointed to an NREL study which found that A/C improvements were greater than previously thought possible. Therefore, it requested the agencies consider increasing the A/C credit cap.³²⁸³

Similarly, the Auto Alliance and Fiat Chrysler suggested raising the cap on A/C efficiency and thermal control technology by 64 percent and combine them under a single cap.³²⁸⁴ Additionally, they proposed increasing A/C efficiency and thermal control technology credits by up to 64 percent.³²⁸⁵ They also proposed that the agencies create new regulatory provisions to handle additional new A/C and thermal technologies.³²⁸⁶

As with increasing the credit caps, manufacturers and suppliers were generally supportive of higher credit caps, or no caps at all, for this combined technology group. However, EPA has decided not to adopt any changes to the caps, including combining the A/C efficiency and

³²⁸⁶ *See, e.g.*, Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

thermal controls menu, due to the uncertainty regarding the menu credit values. Additional uncertainty exists for these technology groups because there are likely synergistic effects between A/C efficiency and thermal technologies that would need to be further considered in determining appropriate credit levels if the two groups of technologies are combined under a single cap. Data is not currently available to consider these effects. Therefore, the agencies are not making any changes to the flexibilities for A/C efficiency improvements in the CO₂ or CAFE program, but may perform research to understand better the relationship between A/C efficiency and thermal technologies that may lead to a different approach in future rulemakings.

3. Flexibilities for Off-Cycle Technologies

“Off-cycle” technologies are those that reduce vehicle fuel consumption and CO₂ emissions in the real world, but for which the fuel consumption reduction benefits cannot be measured or cannot be fully measured under the 2-cycle test procedures (city, highway or correspondingly FTP, HFET) used to determine compliance with the fleet average standards. The CAFE city and highway test cycles, collectively referred to as the 2-cycle laboratory compliance tests (or 2-cycle tests), were developed in the early 1970s. The city test simulates city driving in the Los Angeles area at that time. The highway test simulates driving on secondary roads (not expressways). The cycles are effective in measuring improvements in most fuel economy improving technologies; however, they are unable to measure or underrepresent certain fuel economy improving technologies because of limitations in the test cycles. For example, off-cycle technologies that improve emissions and fuel economy at idle (such as “stop start” systems) and those technologies that improve fuel economy to the greatest extent at expressway speeds (such as active grille shutters which improve aerodynamics) receive less than their real-world benefits in the 2-cycle compliance tests.

Starting with MY 2008, EPA began employing a “five-cycle” test methodology to measure fuel economy for the purpose of improving new car window stickers (labels) and giving consumers better information about the fuel economy they could expect under real-world driving conditions.³²⁸⁷ However, for CO₂ and CAFE compliance, EPA continues to use the established “two-cycle” test methodology.³²⁸⁸ As learned through development of the “five-cycle” methodology and prior rulemakings, there are technologies that provide real-world CO₂ emissions and fuel consumption improvements, but those improvements are not fully reflected on the “two-cycle” test. EPA established the off-cycle credit program to provide an appropriate level of CO₂ credit for technologies that achieve CO₂ reductions, but are normally not chosen as a CO₂ control strategy because their CO₂ benefits are not measured on the specified 2-cycle test.

Currently, EPA has three compliance pathways, and intends substantially to streamline the processes for using off-cycle compliance flexibilities. The first approach allows manufacturers to gain credits without having to prove the benefits of the technologies on a case-

³²⁸⁷ <https://www.epa.gov/vehicle-and-fuel-emissions-testing/dynamometer-drive-schedules>.

³²⁸⁸ The city and highway test cycles, commonly referred to together as the 2-cycle tests are laboratory compliance tests required by law for CAFE and are also used for determining compliance with the GHG standards.

by-case basis. A predetermined list or “menu” of credit values for specific off-cycle technologies exists and became effective starting in MY 2014.³²⁸⁹ This pathway allows manufacturers to use credit values established by EPA for a wide range of off-cycle technologies, with minimal or no data submittal or testing requirements.³²⁹⁰ Specifically, EPA established a menu with a number of technologies that have real-world CO₂ and fuel consumption benefits not measured, or not fully measured, by the two-cycle test procedures, and those benefits were reasonably quantified by the agencies at that time. For each of the pre-approved technologies on the menu, EPA established a quantified default value that is available without additional testing. Manufacturers must demonstrate that they were in fact using the menu technology, but not required to conduct testing to quantify the technology’s effects, unless they wish to receive a credit larger than the default value. The default values for these off-cycle credits were largely determined from research, analysis, and simulations, rather than from full vehicle testing, which would have been both cost and time prohibitive. EPA generally used conservative predefined estimates to avoid any potential credit windfall.³²⁹¹

For off-cycle technologies not on the pre-defined technology list, or obtained through petitioning, EPA created a second pathway which allows manufacturers to use 5-cycle testing to demonstrate and justify off-cycle CO₂ credits.³²⁹² EPA established this alternative for a manufacturer to demonstrate the benefits of the technology using 5-cycle testing. The additional emissions tests allow emission benefits to be demonstrated over some elements of real-world driving not captured by the CO₂ compliance tests, including high speeds, rapid accelerations, and cold temperatures. Under this pathway, manufacturers submit test data to EPA, and EPA determines whether there is sufficient technical basis to approve the off-cycle credits. No public comments are required for manufacturers seeking credits using the EPA picklist menu or using 5-cycle testing.

The third pathway EPA designed for gaining off-cycle credits allows manufacturers that believe their specific off-cycle technology, either on the EPA picklist menu or not, achieves larger improvements to apply for greater credits and fuel consumption improvement values with

³²⁸⁹ See 40 CFR 86.1869-12(b).

³²⁹⁰ The Technical Support Document (TSD) for the 2012 final rule for MYs 2017 and beyond provides technology examples and guidance with respect to the potential pathways to achieve the desired physical impact of a specific off-cycle technology from the menu and provides the foundation for the analysis justifying the credits provided by the menu. The expectation is that manufacturers will use the information in the TSD to design and implement off-cycle technologies that meet or exceed those expectations in order to achieve the real-world benefits of off-cycle technologies from the menu.

³²⁹¹ While many of the assumptions made for the analysis were conservative, others were “central.” For example, in some cases, an average vehicle was selected on which the analysis was conducted. In that case, a smaller vehicle may presumably deserve fewer credits whereas a larger vehicle may deserve more. Where the estimates are central, it would be inappropriate for the agencies to grant greater credit for larger vehicles, since this value is already balanced by smaller vehicles in the fleet. The agencies take these matters into consideration when applications are submitted to modify credits on the menu.

³²⁹² See 40 CFR 86.1869-12(c). EPA proposed a correction for the 5-cycle pathway in a separate technical amendments rulemaking. See 83 FR 49344 (Oct. 1, 2019). EPA is not approving credits based on the 5-cycle pathway pending the finalization of the technical amendments rule.

supporting data using a case-by-case demonstration approach. This third pathway allows manufacturers to seek EPA approval, through a notice and comment process, to use an alternative methodology other than the menu or 5-cycle methodology for determining the off-cycle technology CO₂ credits.³²⁹³

Due to the uncertainties associated with combining picklist technologies and the fact that some uncertainty is introduced because off-cycle credits are provided based on a general assessment of off-cycle performance, as opposed to testing on the individual vehicle models, EPA established caps that limit the amount of credits a manufacturer may generate using the EPA picklist menu. Off-cycle technology is capped at 10 grams/mile per year on a combined car and truck fleet-wide average basis. EPA also established minimum penetration rates for several of the listed technologies, as a condition for generating credit from the list, as a further way to encourage their adoption. No caps were established for technologies gaining credits through the petitioning or 5-cycle approval methodologies.

a) *Consideration of Eliminating A/C and Off-Cycle Adjustments in the CO₂ and CAFE Programs*

The agencies sought comments in the NPRM on whether to remove the A/C and off-cycle flexibilities from the CAFE program and adjust the stringency levels accordingly based upon concern that the flexibilities might distort the market. Several commenters provided responses concerning the feasibility of removing any of these flexibilities. Commenters included the Auto Alliance, the National Automobile Dealers Association, Global Automakers, the Alliance for Vehicle Efficiency, ACEEE, BorgWarner, Fiat Chrysler, General Motors, International Council on Clean Transportation, Toyota, and UCS. Other comments were received requesting that the agencies look into expanding the flexibilities by including more technologies.

There was widespread support from commenters for retaining these flexibilities for A/C and off-cycle technologies in the CO₂ and CAFE programs. Commenters preferred that the agencies continue to include the flexibilities, believing them to enable real world fuel economy improvements and compliance with CO₂ and CAFE standards with a more cost effective combination of technologies. The agencies agree that these programs achieve real world fuel economy improvements and that keeping the flexibilities may enable more cost effective technology combinations to achieve those real world fuel economy improvements. For MY 2017, manufacturers introduced a wide variety of low-cost technologies through the A/C and off-cycle flexibilities that increased the overall industry's CAFE performance by 1.1 mpg. The agencies also acknowledge that the continued use of these flexibilities under the EPA program since 2012 warrants consideration due to automakers' and suppliers' significant investments in developing the technologies, which could result in stranded capital should the agencies discontinue them and manufacturers choose to remove the technologies. For these reasons, the

³²⁹³ See 40 CFR 86.1869-12(d).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

agencies have decided to continue allowing manufacturers to use the existing flexibilities for A/C efficiency and off-cycle technologies for future model years.

b) Final Decisions in Response to Manufacturers' and Suppliers' Requests

Automakers, trade associations, and auto suppliers recommended several changes to the current off-cycle credit program.³²⁹⁴ Prior to the NPRM, automakers and suppliers suggested changes to the off-cycle program, including:

- Streamlining the program in ways that would give auto manufacturers more certainty and make it easier for manufacturers to earn credits;
- Expanding the current pre-defined off-cycle credit menu to include additional technologies and increasing credit levels where appropriate;
- Eliminating or increasing the credit cap on the pre-defined list of off-cycle technologies and revising the thermal technology credit cap; and
- Creating a role for suppliers directly to seek approval of their technologies.

EPA requested comments on several aspects of the off-cycle credits program and, as discussed below, both EPA and NHTSA are adopting some modest changes, primarily to help streamline and clarify their programs, and to ease the implementation burden for manufacturers and the government. The agencies are not adopting a significant expansion of the programs in this rule, as also discussed below. EPA and NHTSA are taking this relatively conservative approach for their off-cycle programs due to the uncertainty that remains in estimating off-cycle benefits of technologies and the need to remain cautious to help ensure that emissions and fuel economy benefits expected through the off-cycle flexibility are realized in the real-world.

(1) Program Streamlining

EPA requested comments on changes to the off-cycle process that would streamline the program. Currently, under the third pathway, manufacturers submit an application that includes the methodology they used to determine the off-cycle credit value and data, which then undergoes a public notice and comment process prior to an EPA decision regarding the application. Each manufacturer separately submits an application to EPA that must undergo a public notice and comment process even if the manufacturer uses a methodology previously approved by EPA for another manufacturer. For example, under the current program, multiple manufacturers have separately submitted applications for high-efficiency alternators and advanced A/C compressors using similar methodologies and producing similar levels of credits. If manufacturers also seek fuel economy improvement values for the CAFE program, they are also required to send the submissions to NHTSA, as EPA consults with NHTSA in its

³²⁹⁴ See generally Alliance/Global Petition.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

determinations for the CAFE program. NHTSA's involvement is discussed in more detail in Section ~~IX.D.3.b)~~IX.D.3.b).

EPA requested comment on revising the regulations to allow all auto manufacturers to make use of a methodology once it has been approved by EPA under the public process, without subsequent applications from other manufacturers having to undergo the same process. This would reduce redundancy in the current program. This would reduce redundancy in the current program. Manufacturers would need to provide EPA with at least the same level of data and detail for the technology and methodology as the manufacturer that went through the initial public notice and comment process.

EPA received supportive comments for streamlining the approval process from auto manufacturers and suppliers. The Auto Alliance commented that it supports all actions that would shorten the time it takes EPA to evaluate and reach decisions on applications through the off-cycle alternative methodology pathway, and that manufacturers should be allowed to use common data from applications that have already been approved.³²⁹⁵ Such common data would include ambient conditions, general consumer behavior data, and general operating and performance data for the same off-cycle technologies. Global Automakers also commented that EPA should streamline efforts to avoid reduplication of applications in situations where multiple automakers have submitted petitions for the same technology and recommended blanket approval for applications using the same specific technologies and calculation and measurement procedures.³²⁹⁶ General Motors commented that when a credit for a new technology is approved for one manufacturer, the EPA decision document announcing that approval can serve as a guidance document that assigns a credit value or calculation methodology for the technology for all manufacturers without requiring duplicative testing.³²⁹⁷ MEMA commented that it would be sufficient to uphold the integrity of the off-cycle program to require the next vehicle manufacturer's application to provide at least the same level of data and details as the original vehicle manufacturer application and to validate the level of credit the next vehicle manufacturer is applying for based on how the technology is applied in its fleet.³²⁹⁸

ACEEE commented that any streamlining of the process by which automakers petition for off-cycle credits must maintain the requirement that a thorough methodology show real-world benefits and ensure adequate opportunity for public review.³²⁹⁹ International Council on Clean Transportation (ICCT), while not commenting on this specific request for comment,

³²⁹⁵ Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³²⁹⁹ ACEEE, Detailed Comments, NHTSA-2018-0067-12122.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

commented that the program should remain unchanged until potential changes can be further analyzed.³³⁰⁰

After considering the comments, consistent with its proposal, EPA is streamlining the approval process as follows: once a methodology for a specific off-cycle technology has gone through the public notice and comment process and is approved for one manufacturer, other manufacturers may follow the same methodology to collect data on which to base their off-cycle credits. Once a methodology is approved, other manufacturers may submit applications citing the approved methodology, but those manufacturers must provide their own necessary test data, modeling, and calculations of credit value specific to their vehicles, and any other vehicle-specific details pursuant to that methodology, to assess an appropriate credit value. This is similar to what occurred, for example, with the advanced A/C compressor, where one manufacturer applied for credits with data collected through bench testing and vehicle testing and subsequent manufacturers applied for credits following the same methodology, but by submitting test data specific to their vehicle models. However, those subsequent applications previously required a public notice and comment process. For future applications, as long as the testing is conducted using the previously-approved methodology, EPA will evaluate the credit application and issue a decision with no additional notice and comment, since the first application that established the methodology was subject to notice and comment.

EPA is not providing blanket approval for a specific credit value, nor amending the requirement that manufacturers collect necessary data or perform modeling or other analyses on their specific vehicle models as the basis for the credit. However, once a methodology has been fully vetted and approved through the public process, EPA believes additional public review of the identical methodology is unnecessarily duplicative. In EPA's experience thus far (for example with high-efficiency alternators and advanced A/C compressors for which EPA has received applications from several manufacturers based on the same methodology), additional public review has yielded no additional substantive public comments. EPA believes this change in the program will help reduce the time necessary for review of applications. EPA will maintain the option to seek additional public comment in cases where the agency believes a new application deviates from a previously approved methodology or raises new issues on which the agency believes it is prudent to seek comment.

EPA also requested comment on revising the regulations to allow EPA to, in effect, add technologies to the pre-approved credit menu without going through a subsequent rulemaking. For example, if one or more manufacturers submit applications with sufficient supporting data for the same or similar technology, the data from that application(s) could potentially be used by EPA as the basis for adding technologies to the menu. EPA requested comment on revising the regulations to allow EPA to establish through a decision document a credit value, or scalable value as appropriate, and technology definitions or other criteria to be used for determining whether a technology qualifies for the new menu credit. As envisioned in the NPRM, this streamlined process of adding a technology to the menu would involve an opportunity for public

³³⁰⁰ International Council on Clean Transportation, Detailed Comments, NHTSA-2018-0067-11741.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

review but not a formal rulemaking to revise the regulations, allowing EPA to add technologies to the menu in a timely manner, where EPA believes that sufficient data exist to estimate an appropriate credit level for that technology across the fleet.

EPA received supportive comments regarding this proposal from auto manufacturers and suppliers who believe that the change would help streamline the program. EPA also received comments from environmental NGOs suggesting that the program should not be changed at this time. After consideration of these comments, the agencies are not revising the regulations to allow technologies to be added to the menu without a rulemaking because EPA believes that menu-based off-cycle credits should be based on a robust demonstration of the technology, consistent with the regulations. The agencies will retain the option to add technologies to the menu through a rulemaking, similar to the approach being taken for high-efficiency alternators and advanced A/C compressors as discussed below, where sufficient data has been collected from multiple manufacturers and vehicle models on which to base a menu credit. The menu credits are meant to be conservative. The agencies are concerned that basing a menu credit on data from only one or a few manufacturers does not guarantee a robust and accurate credit level representing vehicles across the fleet. At this time, the agencies continue to believe a rulemaking process with full opportunity for public comment remains the best approach for adding technologies to the menu. A rulemaking ensures that all stakeholders including automakers have an opportunity to provide data to support an appropriate and conservative credit level for the fleet. This approach also provides an incentive for manufacturers to, in the meantime, continue to perform testing and provide actual data that could eventually be used to inform a rulemaking process to add a technology to the menu. The agencies want to preserve that element of the program to maintain the integrity of off-cycle credits representing real-world reductions.

(2) *A/C and Off-Cycle Application Process*

The agencies received several comments, in addition to those received in the petitions from the Auto Alliance and Global Automakers, discussed below, on the application process for approving additional A/C and off-cycle credits. Commenters included the Global Automakers, the Auto Alliance, Volkswagen, Edison Electric Institute, Ford, Fiat Chrysler, NCAT, Toyota, General Motors, and DENSO International.

Fiat Chrysler, Ford, Volkswagen, DENSO International, Global Automakers, and the Auto Alliance requested that the agencies respond more quickly to applications for A/C and off-cycle technologies.³³⁰¹ They prefer that petitions be addressed before the close of a model year so manufacturers can have a better idea of what credits they will earn.

The agencies agree that responding to petitions before the end of a model year is beneficial to manufacturers and the government. Manufacturers would have a better idea of the

³³⁰¹ Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943-50; Ford, Detailed Comments, NHTSA-2018-0067-11928-15; Volkswagen, Detailed Comments, NHTSA-2017-0069-0583-13; DENSO, Detailed Comments, NHTSA-2018-0067-11880-5; Global Automakers, Detailed Comments, NHTSA-2018-0067-12032-50; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073-120.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

approved credits, and the government could carry-out its compliance processes more efficiently. EPA structured the A/C and off-cycle programs to make it possible to complete the processes by the end of the model year so manufacturers could submit their final reports within the required deadline, 90 days after the calendar year. However, delays currently exist due to the timing needed to review and approve technologies for the first time and issue *Federal Register* notices seeking public comments. The agencies anticipate these problems will resolve themselves as the off-cycle program reaches maturity and EPA initiates the new streamlining approaches adopted in this final rule, discussed in the previous section.

The agencies are also aware that delays exist because manufacturers frequently submit late applications, new applications, and ask for retroactive credits or FCIVs for off-cycle technologies equipped on previously-manufactured vehicles after the model year has ended. As required under both the CO₂ and CAFE programs, manufacturers are to submit applications for off-cycle credits and FCIVs *before* the beginning of each compliance model year, to enable the agencies to make better informed final decisions before the model year ends. Consequently, NHTSA and EPA are considering incorporating deadlines for manufacturers and other actions the government may take to expedite the processes.

In the meantime, to expedite the process of approvals, the agencies will enforce existing EPA and NHTSA regulations requiring manufacturers to notify and report information on the technologies before the beginning of the model year. Presently, manufacturers must notify EPA in their pre-model year reports, and in their applications for certification, of their intention to generate any A/C and off-cycle credits before the model year, regardless of the methodology for generating credits.³³⁰² Manufacturers choosing to generate credits using the alternative EPA-approval methodology are required to submit a detailed analytical plan to EPA *prior to a model year* in which a manufacturer intends to seek these credits. The manufacturer may seek EPA input on the proposed methodology prior to conducting testing or analytical work, and EPA will provide input on the manufacturer's analytical plan. The alternative demonstration program must be approved in advance by the Administrator. NHTSA has similar provisions for its projections reports in which detailed information on the technologies must be included in those submissions during the month of December before the model year.³³⁰³ NHTSA's provisions also require manufacturers to submit information to NHTSA at the same time as to EPA. Consequently, the eligibility of a manufacturer to gain off-cycle CO₂ credits or CAFE adjustments for a given compliance model year requires appropriate submissions to the agencies. The agencies intend to enforce these provisions starting with the 2020 compliance model year. Manufacturers may resubmit MY 2020 information until May 1, 2020. The agencies will deny any manufacturers' late submissions after that time, including those requesting retroactive credits for previous compliance model years. However, manufacturers who properly submit information ahead of time will be allowed to make corrections to resolve inadvertent errors during or after the model year. The agencies believe that enforcing the existing submission requirements will be the most

³³⁰² See 40 CFR 86.1869(a) and 40 CFR 1843-01.

³³⁰³ See 49 CFR Part 537.7(c)(7) and 49 CFR Part 531.6 and 533.6.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

efficient approach to expedite approvals until new regulatory deadlines or additional requirements can be adopted.

Fiat Chrysler, Volkswagen, Global Automakers, and the Auto Alliance further suggested the EPA issue a *Federal Register* notice for submitted off-cycle applications within 30 days and issue a final decision within 90 days.³³⁰⁴

As mentioned, EPA is addressing the issues raised by commenters by streamlining its required regulatory processes to eliminate the need to submit multiple *Federal Register* notices concerning requests from different manufacturers for the same technology. Under this streamlined process, after a technology is approved for the initial manufacturer(s), EPA will approve any subsequent manufacturer requests for the same technology upon receipt of data submissions validating the benefit specific to their model types.

General Motors, Toyota, NCAT, Fiat Chrysler, Ford, Volkswagen, DENSO, Edison Electric Institute, Global Automakers, and the Auto Alliance further suggested that technologies approved for multiple manufacturers, to the extent additional automakers will have the same requests, be added to the “picklist” to encourage additional implementation of the technology. Doing so would reduce duplicative efforts for the agencies, as well as manufacturers.³³⁰⁵

As mentioned previously, the agencies have decided to allow only new technologies to be added to the picklist through the regular rulemaking processes including the opportunity for notice and public comment.

General Motors, DENSO, Global Automakers, and the Auto Alliance further suggested that suppliers should be allowed to request a “grams per mile” value for their off-cycle technologies. They asserted that this will provide certainty to manufacturers before they buy that technology.³³⁰⁶ Toyota and the Auto Alliance suggested that the agencies could improve efficiency and reduce burdens by creating a “toolbox,” methodologies that manufacturers can apply to the analysis of off-cycle credit opportunities.³³⁰⁷ They stated it would additionally help

³³⁰⁴ Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943; Volkswagen, Detailed Comments, NHTSA-2017-0069-0583; Global Automakers, Detailed Comments, NHTSA-2018-0067-12032; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³³⁰⁵ General Motors, Detailed Comments, NHTSA-2018-0067-11858; Toyota, Detailed Comments, NHTSA-2018-0067-12150; NCAT, Detailed Comments, NHTSA-2018-0067-11969; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943; Ford, Detailed Comments, NHTSA-2018-0067-11928; Volkswagen, Detailed Comments, NHTSA-2017-0069-0583; DENSO, Detailed Comments, NHTSA-2018-0067-11880; Edison Electric Institute, Detailed Comments, NHTSA-2018-0067-11918; Global Automakers, Detailed Comments, NHTSA-2018-0067-12032; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³³⁰⁶ General Motors, Detailed Comments, NHTSA-2018-0067-11858; DENSO, Detailed Comments, NHTSA-2018-0067-11880; Global Automakers, Detailed Comments, NHTSA-2018-0067-12032; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³³⁰⁷ Toyota, Detailed Comments, NHTSA-2018-0067-12150; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturers if the agency would issue guidance letters and decision documents for off-cycle credit approvals.³³⁰⁸

The agencies believe that developing a “toolbox” may not be possible due to the development of new and emerging technologies, and manufacturers’ different approaches for evaluating the benefits of the technologies. The agencies will consider additional guidance, if feasible, as the programs further matures in the approval process of technologies and if the agencies can identify consistent methodologies that may help manufacturers analyze off-cycle technologies.

NCAT and General Motors requested more transparency in the A/C and off-cycle approval process. They suggested that the agencies could provide reports including off-cycle credits approved by vehicle make and model and provide further clarification of data requirements that influenced the decision process.³³⁰⁹

EPA and NHTSA have separate approaches for sharing information on these flexibilities, to provide public transparency. EPA already provides information on the manufacturers, technologies, and credits gained for each model year in its end of the year compliance report. NHTSA plans to share similar information on its PIC and to provide projected data on the market penetration rates of the technologies as soon as it starts receiving information through its new reporting templates for the 2023 compliance model year.

(3) *High Efficiency Alternators and Advanced Air Conditioning (A/C) Compressors*

EPA sought comments on modifying the off-cycle picklist menu to add certain technologies for which EPA has collected sufficient data to set an appropriate credit level. More specifically, EPA received data from multiple manufacturers on high-efficiency alternators and advanced air conditioning (A/C) compressors that could serve as the basis for new menu credits for these technologies.³³¹⁰ EPA requested comments on adding these two technologies to the menu including comments on credit level and appropriate definitions. EPA also requested comments on other off-cycle technologies that EPA could consider adding to the menu including supporting data that could serve as the basis for the credit.

Toyota, General Motors, BorgWarner, Fiat Chrysler, the Auto Alliance, Global Automakers, MECA, DENSO, SAFE, and Volkswagen submitted responses on the off-cycle picklist. General Motors, Volkswagen, Fiat Chrysler, Global Automakers, and the Auto Alliance all supported adding high-efficiency alternators and advanced A/C compressors to the

picklist.³³¹¹ They commented that these technologies have already been approved for off-cycle credits through the petition process multiple times. They contend that it would be less burdensome if the technologies would be added to the pre-approved off-cycle credit list. That said, they were concerned about being constrained by the off-cycle caps.³³¹²

The agencies believe that adding high-efficiency alternators and advanced A/C compressors to the menu is a reasonable step to help streamline the program by allowing manufacturers to select the menu credit rather than continuing to seek credits through the public approval process. Therefore, EPA is revising the regulations to add these two technologies to the menus. The high-efficiency alternator is being added to the off-cycle credits menu, and the advanced A/C compressor with a variable crankcase valve is being added to the menu for A/C efficiency credits. The credit levels are based on data previously submitted by multiple manufacturers through the off-cycle credits application process, and discussed in the NPRM. The high efficiency alternator credit is scalable with efficiency, providing an increasing credit value of 0.16 grams/mile CO₂ per percent improvement as the efficiency of the alternator increases above a baseline level of 67 percent efficiency. The advanced A/C compressor credit value is 1.1 grams/mile for both cars and light trucks.³³¹³

EPA also received comments from the Auto Alliance, Fiat Chrysler, General Motors, Mitsubishi, Gentherm, ITB, and MEMA on a variety of individual technologies that they suggest adding to the menu.³³¹⁴ These commenters provided little data to support their recommended credit levels. The Auto Alliance and Alliance for Vehicle Efficiency further asserted that flexibility mechanisms are increasingly important and there is a need to develop unconventional and non-traditional fuel economy technologies to meet standards.³³¹⁵ They requested additional pre-defined and pre-approved technologies to be included in this regulation.³³¹⁶

The agencies have reviewed manufacturers' requests for adding additional technologies to the picklist and concluded that there is insufficient data in the record at this time on which to

base an appropriate menu credit value for the technologies. Therefore, none of these technologies are being added to the menu at this time. Given the limited data and uncertainty, EPA also does not believe it would be appropriate to add any of the technologies to the menu without an opportunity for public review and comment. Although the agencies are not adding these technologies to the menu at this time, manufacturers may seek off-cycle credits for these technologies through the other program pathways.

(4) *Stop-Start Technology*

In 2014, EPA approved additional credits for the Mercedes-Benz's stop-start system through the off-cycle credit process based on data submitted by Mercedes-Benz on fleet idle time and its system's real-world effectiveness (i.e., how much of the time the system turns off the engine when the vehicle is stopped).³³¹⁷ Prior to proposal, multiple auto manufacturers requested that EPA revise the table menu value for stop-start technology based solely on one input value EPA considered, idle time, in the context of the Mercedes-Benz stop-start system. No manufacturers provided additional data on any of the other factors evaluated during consideration of a conservative credit value for stop-start systems. Stop-start systems vary significantly in hardware, design, and calibration, leading to wide variations in the amount of idle time during which the engine is actually turned off in real-world driving. EPA has learned that some stop-start systems may be less effective in the real-world than the agency estimated in its 2012 rulemaking analysis, for example, due to systems having a disable switch available to the driver, or because stop-start systems can be disabled under certain temperature conditions or auxiliary loads, which would offset the benefits of the higher idle time estimates. EPA requested additional data from manufacturers, suppliers, and other stakeholders regarding a comprehensive update to the stop-start off-cycle credit table value. EPA did not receive any additional real-world system effectiveness data from commenters on which to base an adjusted credit level. MEMA commented that EPA should base an increase in the credit on the agencies' updated estimated effectiveness of stop-start technology in the Draft Technical Assessment Report (TAR), which shows a 67 percent increase in effectiveness.^{3318, 3319} However, EPA notes that this estimate is for system effectiveness over the 2-cycle test procedures and, therefore, is not an appropriate basis to adjust the off-cycle credits. The agencies are not adjusting the menu credits for stop-start systems at this time. Manufacturers may apply for additional credits if they are able to collect data demonstrating a system effectiveness that would serve as the basis for those credits.

(5) *Menu Credit Cap*

The off-cycle menu currently includes a fleetwide cap on credits of 10 grams/mile to address the uncertainty surrounding the data and analysis used as the basis of the menu credits.³³²⁰ Prior to proposal, some stakeholders expressed concern that the current cap may constrain manufacturers' future ability to fully utilize the menu especially if the menu is expanded to include additional technologies, as described above. For example, Global Automakers suggested raising the cap from 10 grams/mile to 15 grams/mile.³³²¹ EPA requested comments on increasing the current cap, for example, from the current 10 grams/mile to 15 grams/mile to accommodate increased use of the menu. EPA also requested comment on a concept that would replace the current menu cap with an individual manufacturer cap that would scale with the manufacturer's average fleetwide target levels. The cap would be based on a percentage of the manufacturer's fleetwide 2-cycle emissions performance, for example at five to ten percent of CO₂ of a manufacturer's emissions fleet-wide target. With a cap of five percent for a manufacturer with a 2-cycle fleetwide average CO₂ level of 200 grams/mile, for example, the cap would be 10 grams/mile.

There was widespread support from automakers and suppliers for removing the cap entirely or raising the cap from 10 grams/mile to 15-20 grams/mile. Toyota, General Motors, BorgWarner, Fiat Chrysler, the Auto Alliance, Global Automakers, MECA, DENSO, SAFE, and Volkswagen submitted responses on the off-cycle cap to EPA.³³²² They argued that the 2-cycle test does not always account for all the benefits a technology provides.³³²³ General Motors, Fiat Chrysler, the Auto Alliance, Global Automakers, and Volkswagen agreed that EPA should remove the 10 grams/mile cap and, if they must keep the cap, increasing it to 15 grams/mile.³³²⁴

Global Automakers commented that, as more technology receives off-cycle credit values, the cap will restrict innovation and therefore EPA should lift the cap now in anticipation of increased use of technologies.³³²⁵ General Motors similarly commented that the cap was an arbitrary limit without any technical justification and that, if the agency was to add emission reduction technologies to the menu these devices could not be effectively incentivized if the 10

grams/mile cap remains in place, since there would be no room under the cap.³³²⁶ General Motors disagreed with the proposal to provide provisional credits that may be taken away if testing does not fully validate the value of the technology. They suggested that as the program continues, manufacturers will continue to find new technologies and will be limited by the cap. They stated that the cap will stifle additional investments for technologies. MEMA commented that if EPA expands the off-cycle technologies menu and continually adds off-cycle technologies to the menu, it is critical that EPA increase or eliminate the cap on the credits gained from the off-cycle menu.³³²⁷

The Auto Alliance argued that putting caps on emerging new technologies will hinder further vehicle investments and improvements. The planning cycle is implemented years out and without a guarantee they will see benefits, the Auto Alliance stated that manufacturers lack incentivization to work toward large technological advances.³³²⁸ The Auto Alliance and Alliance for Vehicle Efficiency further asserted that flexibility mechanisms are increasingly important and there is a need to develop unconventional and non-traditional fuel economy technologies.³³²⁹

ACEEE commented that the off-cycle credit menu cap should not be increased or modified without the agency first defining any other changes it might consider making to the off-cycle credit program and this should be done through a separate NPRM and public review process.³³³⁰ ICCT commented that if the agencies allow more use of off-cycle credits without clear validation of their real-world benefits, the regulations cannot serve their intended objectives to reduce CO₂ and fuel use.³³³¹

EPA also received a few comments warning about the risks of removing the caps and over incentivizing the CAFE and CO₂ programs. ACEEE pointed out that while expanding and updating the flexibilities that incentivize innovation and research is a great method to increase fuel efficiency, it is important to put a time limit on those incentives and carefully design them so manufacturers do not take advantage. ACEEE argued that, if these flexibilities are not implemented thoughtfully, they can end up reducing the program benefits.³³³² UCS commented that, given the potential interaction from multiple incentives, it is important to consider the combined impacts of flexibilities on the overall stringency of the regulation. UCS stated that given the potential for widespread harm, credits within the program should be severely limited, and the agencies' assessment of the impacts of such incentives should be extremely conservative

in order to promote increased environmental benefits of the fuel economy and carbon dioxide emissions standards.³³³³

The agencies are not increasing the 10 grams/mile menu credit cap at this time. EPA established the 10 grams/mile credit cap to address the uncertainty surrounding the data and analysis used as the basis of the menu credits, and agrees with ACEEE, ICCT, and UCS that sufficient uncertainty remains such that increasing the current cap is not justified. As noted in the 2012 final rule, EPA included the fleet-wide cap because the default credit values were based on limited data, and also because the agencies recognized that some uncertainty is introduced when credits are provided based on a general assessment of off-cycle performance as opposed to testing on the individual vehicle models.³³³⁴ That uncertainty has not significantly diminished since the 2012 final rule. Also, over the course of implementing the program, EPA has encountered issues with the regulatory definitions currently in place for some technologies. The regulations specify that manufacturers may claim credits for technologies that meet the regulatory definitions. However, there have been instances where manufacturers have claimed credits for a technological approach that they have argued meets the regulatory definition, but EPA found that the technology was not implemented consistent with the technological approach envisioned when the off-cycle program was established. This has raised questions of whether the credits for the technological approach in question truly represent real-world reductions, and whether the credits should ultimately be allowed. These types of issues have resulted in uncertainty, which can lead to delays in credit calculations, competitive inequities, as well as increased burden on the agency to review and resolve issues. The caps continue to serve as an important measure against the loss of emissions reductions and fuel savings given the uncertainty in the credit values as the program is implemented. Since the agencies are not expanding the menu beyond the two technologies discussed above, the agencies believe there remains enough room under the cap such that the menu may continue to serve its purpose as a source of off-cycle credits. Although a few manufacturers approached the cap limit in MY 2018, the fleet average menu credit was 4.7 grams/mile, less than half the cap value.³³³⁵ If the agencies undertake a rulemaking in the future to modify the menu or regulatory definitions, the agencies may re-evaluate the cap levels at that time. The agencies note that the cap only applies to credits based on the menu. Under the current program, manufacturers may apply for credits beyond the cap through other available pathways based on a demonstration of off-cycle technology emission reduction data for their fleets.

The agencies have decided to continue the option to add technologies to the menu only through the rulemaking process and, for this final rule, have decided to add two new picklist items; one for high-efficiency alternators and another for advanced A/C compressors. No further incentives are being adopted for advanced technology vehicles as discussed previously. The agencies stated that they will only add technologies when sufficient data has been collected from multiple manufacturers and vehicle models on which to base a menu credit. Accordingly, the

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

agencies believe this approach ensures that conservative, robust and accurate credit levels are being added representing vehicles “on average” across the fleet.

Finally, the agencies have been studying how the combination of flexibilities and incentives may adversely affect the stringency of CO₂ and CAFE regulations. The agencies are aware of an instance in which combining incentives for alternative fueled vehicles and incentives for A/C and off-cycle technologies allowed one manufacturer to increase in CAFE fleet performance to a combined average of 516.8 mpg for MY 2017, a curious result. EPA and NHTSA are continuing to evaluate the issue of combining incentives and flexibilities and may address this issue further in the future.

(6) *Eligibility*

Though, in the NPRM, EPA did not explicitly request comment on the eligibility criteria for determining what technologies are eligible for off-cycle credits, EPA received comments on this topic. UCS commented that regulations should be clarified so that the program does not result in unwarranted credits for baseline technologies, noting that in the 2012 final rule EPA stated that technologies integral or inherent to the basic vehicle design were not eligible for credits and specifically excluded technologies identified by the agency as technologies a manufacturer may use to meet the two-cycle CO₂ standards.³³³⁶ ACEEE commented that off-cycle credits should be limited to new and innovative technologies and, that to be eligible for credit, a technology must reduce emissions from the vehicle receiving the credit (as opposed to other vehicles on the road, for example, through system effects of technologies designed for crash avoidance or improving traffic flow).³³³⁷ The Auto Alliance also commented in the area of eligibility, suggesting regulatory changes that would allow off-cycle credits for any technology where the manufacturer could demonstrate an off-cycle emissions benefit.³³³⁸ The Auto Alliance commented that the program is intended to provide credit for technologies that provide more fuel economy and CO₂ emissions reduction benefit in the real-world than is realized in FTP and HFET on-cycle testing and that a baseline technology should be eligible for such credits.

Given the various public comments on eligibility of technologies for off-cycle credits, the agencies are clarifying the regulations regarding technology eligibility, consistent with the intent and EPA’s interpretation of the 2012 rule, as expressed in the preamble to the proposed and final rules. The agencies believe that clarifying the regulations will reduce confusion among manufacturers as to what technologies are eligible and reduce the overall program burden associated with EPA staff giving continued guidance to manufacturers regarding eligibility, as detailed in the 2012 rule preamble. Eligibility was thoroughly addressed in the 2012 final rule preamble, but the regulations were not as clear, which has led to confusion on the part of some manufacturers and delays in reviewing credit applications.³³³⁹ The agencies are not establishing

³³³⁶ UCS, Detailed Comments, NHTSA-2018-0067-12039.

³³³⁷ ACEEE, Detailed Comments, NHTSA-2018-0067-12122.

³³³⁸ Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³³³⁹ 77 FR 62726-36, 62835-37.

a new policy regarding eligibility, only amending the language reflecting the existing policy in the regulations for sake of clarity.

As noted in the 2012 final rule preamble, the goal of the off-cycle credits program is to provide “an incentive for the development and use of additional technologies to achieve real-world reductions in CO₂ emissions.”³³⁴⁰ EPA further stated that the intent of the program is to “provide an incentive for CO₂ and fuel consumption reducing off-cycle technologies that would otherwise not be developed because they do not offer a significant 2-cycle benefit.”³³⁴¹ The regulation at 40 CFR 86.1869-12(a) provides that manufacturers may generate credits for CO₂ reducing technologies “where the CO₂ reduction benefit for the technology is not adequately captured on the Federal Test Procedure and/or Highway Fuel Economy Test.” The regulation continues: “[t]hese technologies must have a measurable, demonstrable, and verifiable real-world CO₂ reduction that occurs outside the conditions of the Federal Test Procedure and the Highway Fuel Economy Test.”

Off-cycle credits are available for technologies that are not utilized when performing FTP and HFET tests because their operation is linked to a condition not found during the 2-cycle testing. For example, heating and cooling systems are not operated during the 2-cycle test, and therefore, efficiency improvements to these systems are not captured at all on the 2-cycle tests. As the 2012 rule’s language indicates, off-cycle credits are not necessarily limited to technologies listed on the menu or off-cycle technologies with no measurable benefit on the FTP and/or HFET. Off-cycle credits may be available for some technologies whose performance is measurable to some extent on the FTP and/or HFET but which perform measurably better off-cycle. Active aerodynamic and stop-start technologies (menu item) are examples. However, there are limits on what the agencies would consider to be an off-cycle technology eligible for credits, as discussed below.

Just as the regulations and preamble to the 2012 final rule listed technologies that the agencies considered to be off-cycle technologies, the preamble also discussed technologies that the agency would not consider off-cycle technologies—i.e., technologies the agencies consider to be “adequately captured” by the FTP and therefore not eligible for off-cycle credits. The preamble specifically noted that engine, transmission, mass reduction, passive aerodynamic design, and base tire technologies are not considered to be off-cycle technologies eligible for credits.³³⁴² These are technologies that are considered to be “integral or inherent to basic vehicle design.”³³⁴³ In response to comments in the final rule, the agencies further clarified that advanced combustion concepts, such as camless engines, variable compression ratio engines, micro air/hydraulic launch assist devices, would not be considered to be eligible for credits.³³⁴⁴ This limitation to eligibility further extends to other engine designs, transmission designs, and

electrification systems not specifically contemplated in the rulemaking, such as Atkinson combustion engines, and 9 and 10 speed transmissions, as well as to other hybrid systems such as 48 Volt technologies. Further, the 2012 final rule preamble stated that technologies included in the agencies' assessment for purposes of developing the standard would not be allowed to generate off-cycle credits and cites the technologies described in Chapter 3 of the 2012 final rule TSD.³³⁴⁵ Finally, off-cycle credits are not available for technologies required to be used by Federal Law or for crash avoidance systems, safety critical systems, or technologies that may reduce the frequency of vehicle crashes.³³⁴⁶

The preamble to the 2012 final rule provides the rationale for what the agency considers an off-cycle technology and, therefore, eligible for credits. Technologies that are integral or inherent to the vehicle are, by necessity, well represented on the 2-cycle test.³³⁴⁷ Examples provided in the preamble are engine, transmission, mass reduction, passive aerodynamic design, and base tire technologies. The control logic for these powertrain components, like the components themselves (i.e. engine and transmission), are constantly active, fully functioning, and operating over the entirety of the FTP and HFET. Similarly, an automatic transmission, regardless of whether it has 6-speeds or 8-speeds, would still be constantly active, fully functioning and operating over the entirety of the FTP and HFET.³³⁴⁸ This would also be true for base engine technologies, advanced combustion concepts, engine components (pistons, valves, camshafts, crankshafts, oil pumps, etc.), and driveline components (individual components of the transmission, axle, and differential).³³⁴⁹

Further, even if these technologies have greater benefits on supplemental test cycles, EPA has explained that it would be difficult to devise accurate A/B testing (i.e., with and without the technology) for these technologies.³³⁵⁰ The 2012 preamble states that "EPA is limiting the off-cycle program to technologies that can be identified as add-on technologies conducive to A/B testing," partly because it would be very difficult accurately to parse out the off-cycle benefits for some integral technologies.³³⁵¹ Because the technology is integral to the vehicle, there would not be an appropriate baseline (i.e., without the technology) vehicle to use for comparison. Vehicles are not built without tires, engines, passive aerodynamics or transmissions.

Also, because these technologies are inherent to the vehicle design, their performance is already reflected in the stringency of the standard and giving credits for these inherent technologies would be a type of double-counting windfall.³³⁵² "[S]ince these methods are integral to basic vehicle design, there are fundamental issues as to whether they would ever

warrant off-cycle credits. Being integral, there is no need to provide an incentive for their use, and (more importantly), these technologies would be incorporated regardless. Granting credits would be a windfall.”³³⁵³ As such, EPA has laid out a clear basis that technological improvements to integral and inherent components are considered to be adequately captured on the FTP and HFET test.

EPA is clarifying the regulations in a manner that is consistent with the intent and our interpretation of the 2012 rule, as expressed in the preambles to the proposed and final rules. The regulations are revised to specify that technologies used primarily to meet the 2-cycle standards are not eligible for off-cycle credits and that only technologies primarily installed for reducing off-cycle emissions would be eligible. The revised regulations specify that the technologies must not be integral or inherent to the basic vehicle design, such as, for example, engine, transmission, mass reduction, passive aerodynamic design, and tire technologies. Exceptions to these general provisions include technologies already specified on the menu, including engine idle stop-start, active aerodynamic improvements, and high-efficiency alternators. These technologies may provide some benefit on the 2-cycle test, but EPA determined in the 2012 rule that they are eligible for off-cycle credits because they are technologies that could be added to vehicles to provide discernable off-cycle reductions.

Regulatory text at 40 CFR 86.1869–12(a) states: “Manufacturers may generate credits for CO₂ reducing technologies where the CO₂ reduction benefit of the technology is not adequately captured on the Federal Test Procedure and/or the Highway Fuel Economy Test,” to which EPA is adding, “such that the technology would not be otherwise installed for purposes of reducing emissions (directly or indirectly) over those test cycles (i.e., on-cycle) for compliance with the [CO₂] standards.” EPA is also adding text to this paragraph of the regulations specifying: “The technologies must not be integral or inherent to the basic vehicle design, such as engine, transmission, mass reduction, passive aerodynamic design, and tire technologies. Technologies installed for non-off-cycle emissions related reasons are also not eligible as they would be considered part of the baseline vehicle design. The technology must not be inherent to the design of occupant comfort and entertainment features except for technologies related to reducing passenger A/C demand and improving A/C system efficiency. Notwithstanding the provisions of this paragraph (a), off-cycle menu technologies included in paragraph (b) of this section remain eligible for credits.”

The agencies believe the above regulatory changes will help reduce confusion over what technologies are eligible for off-cycle credits, refocusing the program on technologies that manufacturers would install on vehicles for purposes of reducing off-cycle emissions rather than obtaining additional credits for technologies installed primarily for 2-cycle emissions reduction or for other reasons not related to emissions. This approach is consistent with the intent of the program as stated in the 2012 final rule to provide an incentive to develop and employ off-cycle technologies not adequately captured on the 2-cycle test procedure.

³³⁵³ See also 76 FR 75024.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Of the technologies recommended by manufacturers to be added to the menu, cooled EGR is an example of a technology that would not be eligible because it is an integral 2-cycle technology that EPA noted in its technology assessment in the MY 2012 rule. Cooled EGR is often an integral component of turbo charged gasoline direct injection engines which is a primary CO₂ reduction strategy used by manufacturers to reduce 2-cycle emissions. The technologies are calibrated to act as a system such that is not possible to separate them in a way that would allow for a clear indication of the off-cycle benefit of cooled EGR as a stand-alone technology.

EPA also received comments from the Auto Alliance regarding several technologies they believe should qualify as active warm-up off-cycle technologies. The Auto Alliance commented that systems that use waste heat from the exhaust gas stream should receive additional credits beyond the menu credits currently established for active engine and transmission warm-up.³³⁵⁴ However, when EPA established the menu credits for active transmission and engine warm-up in the 2012 rule, EPA envisioned waste heat from the exhaust as the primary source of heat to quickly bring the system to operating temperature as the basis for the warm-up technology credits.³³⁵⁵ Therefore, EPA does not believe additional credits, as suggested by the Auto Alliance, are warranted. EPA further notes that the definitions for active engine and transmission warm-up specify that “waste heat” be used in active warm-up technologies in order to qualify for the credits.³³⁵⁶ If a system first directs heat to warm the engine oil or warm the interior cabin, and only then to the engine or transmission, thereby delaying active warm-up, EPA would not view that heat as waste heat since it is serving other purposes during initial vehicle warm-up. EPA would also not consider this approach to be warming up the engine or transmission “quickly” due to the potentially significant delay in warm-up activation. In developing the active warm-up credits, EPA focused on systems using heat from the exhaust as a primary source of waste heat because that heat would be available quickly and also be exhausted by the vehicle and otherwise unused.

EPA allowed for the possible use of other sources of heat such as coolant as the basis for credits as long as those methods would “provide similar performance” as extracting the heat directly from the exhaust system.³³⁵⁷ However, EPA may require manufacturers to demonstrate that the system is based on “waste heat” or heat that is not being preferentially used by the engine or other systems to warm-up other areas like engine oil or the interior cabin. Systems using waste heat from the coolant do not qualify for credits if their operation depends on, and is delayed by, engine oil temperature or interior cabin temperature. As the engine and transmission components are warming up, the engine coolant and transmission oil do not have any ‘waste’ heat available for warming up anything else on the vehicle. During engine and transmission warm-up, the only waste heat source in a vehicle with an internal combustion engine is the

³³⁵⁴ Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

³³⁵⁵ See Joint Technical Support Document: Final Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, EPA-420-R-12-901, August 2012, p. 5-96 - 5-100.

³³⁵⁶ 40 CFR 86.1869-12(b)(4)(v) and (vi).

³³⁵⁷ See Joint Technical Support Document: Final Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, p. 5-99, EPA-420-R-12-901, August 2012.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

engine exhaust as the transmission and coolant have not reached warmed-up operating temperature and therefore do not have any heat to share. Conserving heat in a transmission is not a rapid transmission warm-up using waste heat. Unless the component with lubricating oil and coolant is operating at its fully warmed-up design temperature, by EPA's definition, that component does not have any waste heat available for transfer from the lubricating oil or coolant to any other device until it has reached its fully warmed-up operating temperature (i.e. the temperature when the cooling system is enabled). A qualifying system may involve a second cooling loop that operates independent of the primary coolant system and is not dependent on or otherwise delayed by, for example, cabin temperature. Evaluating whether such systems qualify for menu credits often requires additional information regarding system design to understand better how the system uses waste heat. Given the complexity of these systems and the need to sometimes consider the details of how a system operates, EPA is not making any changes to the menu regarding warm-up technologies.

The Auto Alliance further commented that active transmission bypass valves should qualify for active transmission warm-up credits.³³⁵⁸ The Auto Alliance commented that traditional transmission oil coolers are always active and sized for extreme or worst-case hot ambient conditions. The coolers will, in colder ambient conditions, keep the transmission temperatures well outside of their most efficient operating range. The bypass valve circumvents the cooler when the transmission is relatively cold preserving the transmission heat, so the transmission warms more quickly. EPA disagrees that this type of approach should be eligible for active transmission warm-up because it does not use waste heat to add heat to the transmission. Instead, it prevents useful heat already present in the transmission from being unnecessarily removed. Also, EPA does not view this type of bypass valve as an off-cycle technology but rather as part of a good engineering design of a transmission cooler system. Many vehicles already are designed with transmission cooler bypass valves. EPA does not believe existing coolers qualify as warm-up technologies simply because they are disabled under cold conditions. This approach does not represent the addition of a new off-cycle warm-up technology but the disabling of an existing cooling technology.

Although the agencies did not consider changes to the program to allow credits for safety-related technologies and autonomous vehicle technologies in the proposal, comments were received both in favor of and not in favor of allowing such credits.³³⁵⁹ The agencies note that the rationale for not allowing off-cycle credits for safety-related or crash avoidance technologies has not changed since the 2012 rule and, therefore, in the proposed rule the agencies did not consider making any changes to allow off-cycle credits for safety-related technologies.³³⁶⁰ The agencies continue to believe that there is a very significant distinction between technologies providing direct and reliably quantifiable improvements to fuel economy and CO₂ emission reductions, and technologies which provide those improvements by indirect means, where the improvement is not reliably quantifiable, and may be speculative (or in many

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

instances, non-existent), or may provide benefit to other vehicles on the road more than for themselves. The agencies also continue to believe that the advancement of crash-related and crash avoidance systems specifically is best left to NHTSA's exercise of its vehicle safety authority.

Auto manufacturers and suppliers also commented that EPA should adopt "eco-innovation" credits approved in the European Union (EU) vehicle CO₂ reduction program as part of the off-cycle credits program.³³⁶¹ No data was provided as to why the credits would be appropriate for the U.S. vehicle fleet. EPA did not consider or request comment on the EU credits program and does not believe the credit levels would necessarily be appropriate for the U.S. fleet given the very different vehicle use and driving patterns between Europe and the U.S. Thus, there is no assurance that the credits would be based on real-world emissions reductions.

EPA received comments from the Auto Alliance and Global Automakers that EPA should automatically award credits if the agency does not take final action within 90 days of receiving a request for credits.³³⁶² Regarding these comments, EPA does not believe such a provision is in keeping with maintaining the integrity of the off-cycle credits program. As discussed above, EPA often requires time to sort through complex issues to determine if the technologies meet the regulatory requirements for receiving credits and whether the credits have been quantified appropriately. In some instances, EPA has received public comments and manufacturer rebuttals to those comments that takes additional time to consider before making a final decision. EPA's goal continues to be to evaluate applications for credits in as timely a manner as is possible given the issues that must be addressed and within the resources available. While EPA's need carefully to consider applications may slow down the approval process or result in credits not being approved, it remains paramount to ensure credits are not provided to technologies that do not provide actual off-cycle benefits, and thereby do not meet the regulations. In the past, longer time frames for EPA review have not caused manufacturers to lose credits where credits are determined by EPA to be warranted under the regulations. EPA believes that the changes EPA is making to the program will help streamline the program and reduce confusion, thus helping to reduce the time necessary to evaluate applications and provide final decisions to manufacturers.

(7) *Supplier Role in the Off-Cycle Credits Program*

Prior to proposal, EPA heard from many suppliers and their trade associations about an interest in allowing suppliers to have a formal, regulatorily defined role in the off-cycle credits program.³³⁶³ EPA requested comment on providing a pathway for suppliers, along with at least one auto manufacturer partner, to submit off-cycle applications for EPA approval. As described in the proposal, under such an approach, an application submitted by a supplier and vehicle manufacturer would establish a credit and/or methodology for demonstrating credits that all auto

³³⁶¹ See, e.g., Mitsubishi, Detailed Comments, NHTSA-2018-0067-12056.

³³⁶³ 83 FR 43461.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturers could then use in their subsequent applications. EPA requested comment on requiring that the supplier be partnered in a substantive way with one or more auto manufacturers to ensure that there is a practical interest in the technology prior to EPA investing resources in the approval process. The supplier application would be subject to public review and comment prior to an EPA decision. However, once approved, subsequent auto manufacturer applications requesting credits based on the supplier methodology would not be subject to public review. Under this proposal, the credits would be available provisionally for a limited period of time, allowing manufacturers to implement the technology and collect data on their vehicles in order to support a continuation of credits for the technology in the longer term. The proposal would also provide that the provisional credits could be included under the menu credit cap since they would be based on a general analysis of the technology rather than manufacturer-specific data.

Auto manufacturers' and suppliers' comments were generally supportive of an expanded role for suppliers in the off-cycle credit program. The Auto Alliance supported allowing a supplier to lead the application process but did not support the provisional credit concept since the follow-up testing conducted by manufacturers may not support the level of credits initially claimed by the supplier, resulting in a lower than anticipated credit.³³⁶⁴ Instead, the Auto Alliance suggested a separate cap for supplier-based credits and noted that manufacturers could submit their own data if they wanted to pursue credits levels that exceeded the cap. General Motors similarly disagreed with the provisional credits that might be rescinded if subsequent testing does not fully validate the value of the technology.³³⁶⁵ MEMA supported the request for comments regarding a supplier-led process but did not support requiring that suppliers have an auto manufacturer partner.³³⁶⁶ MEMA commented that there would be no incentive for a supplier to go through the product/technology development process, collect the necessary data, and undertake the full application process for a product/technology that would not generate manufacturer interest.

EPA is not adopting revisions to the regulations to broaden the role of suppliers in the off-cycle credit program at this time. EPA believes such an approach would require additional study and comments regarding the appropriate means of integrating manufacturer data with supplier data in order to ensure the validity of the credits and the integrity of the program. In light of these issues, EPA believes additional discussions with interested parties and an opportunity for public comment, both of which are beyond the scope of this rulemaking, are needed. EPA continues to believe such an approach could encourage the further development of off-cycle technologies, but must be done in a reasonable way that ensures the credits are based on real-world emissions reductions. Under the approach suggested by the Auto Alliance, manufacturers could claim supplier-based credits indefinitely and EPA may never receive any manufacturer data substantiating the credits unless that data supported a credit that exceeded that

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

established through the supplier process. EPA is concerned such a one-way ratchet approach may result in the loss of emissions benefits and undermining the integrity of the off-cycle credit program. EPA also remains concerned about the increased volume of credit applications EPA would need to evaluate including potentially frivolous requests making dubious claims regarding emissions benefits for technologies that manufacturers would have no interest in using. EPA understands MEMA's perspective on the issue of requiring a manufacturer partner, but a supplier-only process would potentially open the door to many requests such that the agency would need to expend considerable additional resources. EPA notes that nothing in the current regulations prevents collaboration between manufacturers and suppliers. Suppliers can and do team with a manufacturer to support the manufacturer's application for credits including providing supporting data and analysis.

(8) *Other Considerations*

Avista Oil commented that EPA should provide an opportunity for credits based on the use of recycled engine oil. Avista Oil commented that there are CO₂ emissions reductions associated with the use of recycled used engine oil and that vehicle manufacturers should be awarded credits for the use of recycled oil. Avista Oil's comment is not within the scope of the rulemaking. The off-cycle credits program focuses on providing credits for technologies that, when applied to the vehicle, the result is lower quantifiable real-world emissions from the vehicle. According to Avista Oil's comment, their recycled oil technology benefits are associated with the recycling process rather than lowering vehicle emissions on the road. Therefore, EPA would not view the technology as eligible for off-cycle credits, and EPA did not propose any other credit specific to the use of recycled engine oil.

Several commenters recommended that EPA raise the credit caps and credit values for thermal controls based on recent work by the National Renewable Energy Lab (NREL). Commenters suggested that credit values should be raised by 64 percent. In response, as discussed in the preamble, EPA is retaining the current menu credit caps and menu credit values due to uncertainties involved with the emissions projections and estimated credit values. Manufacturers may generate additional credits through the off-cycle credits program using the other two pathways by providing individual vehicle data. EPA recognizes additional modeling analysis has been performed by NREL that indicates the potential benefit of all thermal technologies including glazing. EPA designed the thermal control program and related caps based on previous NREL work and applied the thermal caps at the current levels to account for the wide range of uncertainties -- including the uncertainty of the benefit from the combination of thermal technologies and the uncertainty highlighted by the different credit levels across the NREL studies. EPA believes the separate current thermal menu program cap and AC efficiency program cap continue to be reasonable for application across the fleet given these uncertainties.

Enhanced Protective Glass Automotive Association (EPGAA) and Vitro commented that the regulations established by the 2012 rule included an oversight in defining the baseline T_{ts} (the metric used to evaluate thermal reflectivity of glass). EPGAA commented that there was an omission in the case of trucks, where the regulations do allow the use of privacy glass in locations other than the windshield and the front doors. The commenter discussed that the reference baseline glass for trucks, SUVs, and CUVs should have already included privacy glass

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

for some of the rearward windows. In response, EPA recognized when the thermal credit program was finalized in 2012 that some of the vehicles within the reference fleet upon which the credits were based were already composed of vehicles with this type of thermal reflective glass. However, the agency found it difficult to estimate what portion of the fleet contained privacy glass and what the Tts rating was for privacy glass across the fleet. Because of this lack of specificity in the fleet composition and glass ratings, we determined that the most appropriate approach was to allow credit for any glass meeting the finalized Tts requirements, and the total thermal cap was designed to account for this and other uncertainties.

Ford and others commented that thermal control technology credit caps should be implemented on a fleet average basis rather than on a “per VIN” basis. These commenters argued that the per VIN basis creates a reporting burden that is misaligned with the current reporting structure and creates program complexity and unnecessary workload. In response, EPA continues to believe that applying the thermal control credit cap on a per vehicle (per VIN) basis is appropriate due to the synergistic effects among these technologies. The CO₂ reduction potential of applying thermal control technologies is limited within any given vehicle. The program has been implemented in this manner since MY2014, and manufacturers have in fact reported the necessary information to generate thermal control credits.

Gentherm, GM, MEMA, and The ITB Group commented that cooled seats should be added to the menu based on the approved GM off-cycle credits application and NREL study. EPA and NHTSA are not adding cooled seat technology to the menu because we have received data from only a single manufacturer. By contrast, for the technologies EPA and NHTSA are adding to the menu in this final rule, we have assessed data from multiple manufacturers. EPA notes however that the streamlining provisions being finalized in this action should facilitate other manufacturers in being able to apply for off-cycle credits by using GM’s methodology.

Finally, on October 1, 2018, EPA proposed a technical correction separate from the SAFE Vehicles rulemaking for the off-cycle credits pathway based on 5-cycle testing (83 FR 49344). This proposal would correct an error in the regulations established as part of the 2012 final rule. Some commenters expressed their support for the correction as part of their SAFE Vehicles rule comments. EPA notes that this correction continues to be part of a separate rulemaking and is not being addressed in the SAFE Vehicles final rule.

c) Final Decisions on the 2016 Alliance/Global Petition

(1) Retroactive A/C and Off-Cycle CAFE adjustments

In 2016, the Alliance and Global submitted a petition for rulemaking, which included requests that: (1) NHTSA allow retroactive credits for A/C and off-cycle incentives for MYs 2012 to 2016; and (2) NHTSA and EPA revisit the average A/C efficiency benefit calculated by EPA applicable to MYs 2012 through 2016. The Alliance/Global argued that A/C efficiency improvements were not properly acknowledged in the CAFE program, and that manufacturers had exceeded the A/C efficiency improvements estimated by the agencies. The petitioners requested that EPA also amend its regulations such that manufacturers would be entitled to additional A/C efficiency improvement benefits retroactively. The petitioners also argued that

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NHTSA incorrectly stated the agency had taken off-cycle adjustments into consideration when setting standards for MYs 2017 through 2025, but not for MYs 2010-2016. The Alliance/Global further contended that because neither NHTSA nor EPA considered off-cycle adjustments in formulating the stringency of the MY 2012-2016 standards, NHTSA should retroactively grant manufacturers off-cycle adjustments for those model years as EPA did. Doing so, they said, would maintain consistency between the agencies' programs.

Of the two agencies, EPA was the first to establish an off-cycle technology program. For MYs 2012 through 2016, EPA allowed manufacturers to request off-cycle credits for "technologies that achieve [CO₂] reductions that are not reflected on current test procedures..."³³⁶⁷ In the subsequent MY 2017 and later rulemaking, NHTSA joined EPA and included an off-cycle program for CAFE compliance. The Alliance/Global petition cited a statement in the MYs 2012-2016 final rule as affirmation that NHTSA took off-cycle adjustments into account in formulating the MYs 2012-2016 stringencies, and therefore should allow manufacturers to earn off-cycle benefits in model years that have already passed.

In the NPRM, NHTSA tentatively decided to retain the structure of the existing A/C efficiency program and not extend it to MYs 2010 through 2016. For the rulemaking for MYs 2012 through 2016, NHTSA determined it was unable to consider improvements manufacturers made to passenger car A/C efficiency in calculating CAFE compliance.^{3368, 3369} However, EPA did consider passenger car improvements to A/C efficiency for that timeframe. To allow manufacturers to build one fleet that complied with both EPA and NHTSA standards, the CAFE and CO₂ standards were offset to account for the differences borne out of A/C efficiency improvements. Specifically, the agencies converted EPA's grams/mile standards to NHTSA mpg (CAFE) standards. EPA then estimated the average amount of improvement manufacturers were expected to earn via improved A/C efficiency. From there, NHTSA took EPA's converted mpg standard and subtracted the average improvement attributable to improvement in A/C efficiency. NHTSA set its standard at this level to allow manufacturers to comply with both standards with similar levels of technology.³³⁷⁰

Likewise, EPA tentatively decided not to modify its regulations to change the way to account for A/C efficiency improvements. EPA believed this was appropriate as manufacturers decided what fuel economy-improving technologies to apply to vehicles based on the standards as finalized in 2010.³³⁷¹ This included deciding whether to apply traditional tailpipe technologies, A/C efficiency improvements, or both. Granting A/C efficiency adjustments to

³³⁶⁷ 75 FR 25341, 25344 (May 7, 2010). EPA had also provided an option for manufacturers to claim "early" off-cycle credits in the 2009-2011 time frame.

³³⁶⁸ At that time, NHTSA stated "[m]odernizing the passenger car test procedures, or even providing similar credits, would not be possible under EPCA as currently written." 75 FR 25557 (May 7, 2010).

³³⁶⁹ 74 FR 49700 (Sept. 28, 2009).

³³⁷⁰ *Id.*

³³⁷¹ In the MY 2017 and later rulemaking, NHTSA reaffirmed its position it would not extend A/C efficiency improvement benefits to earlier model years. 77 FR 62720 (Oct. 15, 2012).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturers retroactively could result in arbitrarily varying levels of adjustments granted to manufacturers, similar to the Alliance/Global request regarding retroactive off-cycle adjustments. Thus, the existing A/C efficiency improvement structure for MYs 2010 through 2016 will remain unchanged.

NHTSA also tentatively decided manufacturers should not be granted retroactive off-cycle adjustments for MYs 2010 through 2016, and presented a number of clarifications to justify the denial. In particular, Alliance/Global pointed to a general statement where NHTSA, while discussing consideration of “the effect of other motor vehicle standards of the Government on fuel economy,” stated that that rulemaking resulted in consistent standards across the program.³³⁷² The Alliance/Global petition took this statement as a blanket assertion that NHTSA’s consideration of all “relevant technologies” included off-cycle technologies. To the contrary, as quoted above, NHTSA explicitly stated it had not considered these off-cycle technologies.³³⁷³

The fact that NHTSA had not taken off-cycle adjustments into consideration in setting its MYs 2012-2016 standards makes granting the Alliance/Global request inappropriate. Doing so could result in a question as to whether the MY 2012-2016 standards were maximum feasible under 49 U.S.C. 32902(b)(2)(B). If NHTSA had considered industry’s ability to earn off-cycle adjustments—an incentive that allows manufacturers to utilize technologies other than those that were being modeled as part of NHTSA’s analysis—the agency might have concluded more stringent standards were maximum feasible. Additionally, granting off-cycle adjustments to manufacturers retroactively raises questions of equity. NHTSA issued its MYs 2012-2016 standards without an off-cycle program, and manufacturers had no reason to anticipate that NHTSA would allow the use off-cycle technologies to meet fuel economy standards. Therefore, manufacturers made fuel economy compliance decisions with the expectation that they would have to meet fuel economy standards using on-cycle technologies. Generating off-cycle adjustments retroactively would arbitrarily reward some (and potentially disadvantage other) manufacturers for compliance decisions they made without the knowledge such technologies would be eligible for NHTSA’s off-cycle program. Thus, NHTSA tentatively decided to deny Alliance/Global’s request for retroactive off-cycle adjustments.

It is worth noting that in the MYs 2017 and later rulemaking, NHTSA and EPA did include off-cycle technologies in establishing the stringency of the standards. As Alliance/Global noted, NHTSA and EPA limited their consideration to stop-start and active aerodynamic features because of limited technical information on these technologies.³³⁷⁴ At that time, the agencies stated they “have virtually no data on the cost, development time necessary,

³³⁷² *Id.*

³³⁷³ Likewise, EPA stated it had not considered off-cycle technologies in finalizing the MYs 2012-2016 rule.

“Because these technologies are not nearly so well developed and understood, EPA is not prepared to consider them in assessing the stringency of the CO₂ standards.” *Id.* at 25438.

³³⁷⁴ Alliance/Global Petition at 7.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturability, etc. [sic] of these technologies. The agencies thus cannot project that some of these technologies are feasible within the 2017-2025 timeframe.”³³⁷⁵

As described above, NHTSA first allowed manufacturers to generate off-cycle technology fuel consumption improvement values equivalent to CO₂ off-cycle credits in MY 2017.³³⁷⁶ In finalizing the rule covering MYs 2017 and later, NHTSA declined to retroactively extend its off-cycle program to apply to model years 2012 through 2016,³³⁷⁷ explaining “NHTSA did not take [off-cycle credits] into account when adopting the CAFE standards for those model years. As such, extending the credit program to the CAFE program for those model years would not be appropriate.”³³⁷⁸

In the NPRM, NHTSA and EPA sought any further comments on the tentative denials of the retroactive requests in the Alliance/Global. The Auto Alliance and Fiat Chrysler provided additional comments on the tentative denial of the petition requests from the Alliance/Global. The commenters cited that the widening gap between the regulatory standards and actual industry-wide new vehicle average fuel economy that has become evident since 2016, despite the growing use of improvement “credits” from various flexibility mechanisms, such as off-cycle technology credits, mobile air conditioner efficiency credits, mobile air conditioner refrigerant leak reduction credits and credits from electrified vehicles.³³⁷⁹ The commenters believe that applying retroactive credits for the new flexibilities for MYs 2012 to 2016 can address the current compliance deficiencies.

Upon consideration of the issue, NHTSA is finalizing its decision to deny any retroactive off-cycle adjustments in the CAFE program for MYs 2012-2016. As mentioned in the NPRM, NHTSA is concerned about the negative impact of allowing retroactive credits, which could undermine the stringency of the MYs 2012-2016 standards. EPA is finalizing its decision not to modify its regulations to change the benefits for A/C efficiency improvements. As mentioned by EPA, the current approach creates uniformity and objectivity in determining A/C efficiency benefits. Consequently, because EPA is maintaining the current A/C determination methodology and NHTSA already considered those A/C adjustments in its MYs 2012-2016 CAFE standards, NHTSA is also finalizing its decisions in this rule to deny any retroactive A/C adjustments in the CAFE program for MYs 2012-2016.

(2) *Petition Requests on A/C Efficiency and Off-Cycle Program Administration*

As discussed above, NHTSA and EPA jointly administer the off-cycle program. The 2016 Alliance/Global petition requested that EPA and NHTSA make various adjustments to the off-cycle program; specifically, the petitioners requested that the agencies should:

- re-affirm that technologies meeting the stated definitions are entitled to the off-cycle credit at the values stated in the regulation;
- re-acknowledge that technologies shown to generate more emissions reductions than the pre-approved amount are entitled to additional credit;
- confirm that technologies not in the null vehicle set but which are demonstrated to provide emissions reductions benefits constitute off-cycle credits; and
- modify the off-cycle program to account for unanticipated delays in the approval process by providing that applications based on the 5-cycle methodology are to be deemed approved if not acted upon by the agencies within a specified timeframe (for instance 90 days), subject to any subsequent review of accuracy and good faith.³³⁸⁰

With respect to Alliance/Global's request regarding off-cycle technologies that demonstrate emissions reductions greater than what is allowable from the menu, this final rule retains that capability. As was the case for MYs 2017-2021, a manufacturer may still apply for FCIVs and CO₂ credits beyond the values listed on the menu, provided the manufacturer demonstrates the CO₂ and fuel economy improvement.³³⁸¹ This includes the two-alternative processes for demonstrating CO₂ reductions and fuel economy improvement for gaining benefits using either the 5-cycle or alternative approval methodologies.³³⁸²

The agencies have considered Alliance/Global's requests to streamline aspects of the A/C efficiency and off-cycle programs in response to the issues outlined above. Among other things, Alliance/Global requested that the agencies consider providing for a default acceptance of petitions for off-cycle credits after a specified period of time, provided that all required information has been provided, to accelerate the processing of off-cycle credit requests. While the agencies agree that the A/C efficiency and off-cycle program should incorporate programmatic improvements, there are significant concerns with the concept of approving petition requests by default because such requests may not address program issues like uncertainty in quantifying program benefits, or general program administration.

Based on its consideration of the issues raised by the Alliance/Global, EPA has adopted in this final rule new processes for streamlining the compliance mechanisms for approving off-cycle and A/C petition as discussed in the preceding section.

³³⁸⁰ Alliance/Global Petition at 20.

³³⁸¹ 77 FR 62837 (Oct. 15, 2012).

³³⁸² 40 CFR 86.1869-12.

(3) *Other EPA Responses to Alliance Requests*

One issue raised in the Alliance/Global Automakers June 2016 petition (item 6 titled “Refrain from Imposing Unnecessary Restrictions on the Use of Credits”) for EPA’s consideration concerns how credits are managed within the CO₂ program. The Alliance and Global Automakers suggested that EPA allow more flexibility in using credits generated under the various credit programs such as air conditioning or off-cycle credits by allowing them to be carried forward or back independently. Under this approach, a manufacturer would be allowed, for example, to carry their air conditioning credits back to cover a previous deficit while running a deficit in a current model year. The Alliance referred to this petition request in their comments, noting they believe the request “remains pertinent in the context of this rulemaking.”

In response, EPA did not raise this issue or any related programmatic changes in the proposal and therefore these comments are not within the scope of the rulemaking. EPA notes the GHG and CAFE programs are harmonized on the aggregation of credits.

The automakers’ petition also requested that EPA correct the multiplier equation in the regulations so that manufacturers may generate the intended number of credits (item 8, “Correct the Multiplier for BEVs, PHEVs, FCVs, and CNGs”). This request concerns an error in the regulations established in the 2012 Final Rule that results in manufacturers generating fewer than intended for MY 2017-2021 vehicles in some cases. In October 2018, in response to this petition request, EPA issued a proposed rule separate from the SAFE Vehicles NPRM to correct the error in the previously established regulations. EPA will continue to address this issue and related comments in that separate rulemaking. CAFE does not include multiplier credits and therefore this is not a harmonization issue.

4. *Specialty Vehicles with Low Mileage (SVLM)*

In response to the NPRM, Volkswagen submitted comments seeking to adopt a new flexibility for specialty vehicles with low mileage (SVLM).³³⁸³ The flexibility would apply to specialty vehicles produced at low volumes and produced for infrequent use. They argued these specialty vehicles do not approach the vehicle miles traveled of typical vehicles. They requested that NHTSA and EPA allow the SVLM flexibility for vehicles that demonstrate limited predicted driving use. The flexibility would allot each manufacturer a limited annual production of 5,000 SVLM vehicles. It was also proposed that, within this limited product volume, each SVLM would retain its footprint derived performance target (per model type), but would utilize a modified VMT for determining any credits or debits associated with the performance of these vehicles within the manufacturer’s fleet.

The agencies have considered the request from Volkswagen for credits or debits and fuel economy adjustments for SVLM vehicles and are denying the request. The agencies note that Congress prescribed alternative (reduced) CAFE standards for low-volume manufacturers,

³³⁸³ Volkswagen, Detailed Comments, NHTSA-2017-0069-0583.

codified in 49 CFR part 525. Low-volume manufacturers' vehicles are often high-end sports cars which do not have significant fuel savings technologies and are not typically driven by their owners for long distances. Congress limited this exemption to manufacturers of fewer than 10,000 passenger automobiles.³³⁸⁴ EPA has a parallel program for low-volume manufacturers. The flexibility proposed by Volkswagen would be in addition to this existing exemption, but Volkswagen does not identify a source of authority for it. The agencies also have a number of questions about how specifically a SVLM concept might be implemented, such as whether every manufacturer would simply identify the 5,000 vehicles with the lowest projected VMT or lowest fuel economy and therefore qualify for credits for 5,000 vehicles every model year, or whether there should be additional criteria for vehicles to be included. The NPRM did not seek comment on a SVLM concept and the agencies did not receive other comments on the requested program. Therefore, the agencies are denying the request for the SVLM concept suggested by Volkswagen.

E. CO₂ and CAFE Compliance Issues Not Addressed in the NPRM

1. CO₂ and CAFE Adjustments for 5-cycle Testing

EPA and NHTSA received several comments requesting that the agencies revise current CAFE test procedures to use EPA's 5-cycle test procedures in place of the 2-cycle test procedures that have been largely unchanged since the inception of the CAFE program, or offset measured 2-cycle test fuel economy and CO₂ emissions for CO₂ and CAFE compliance. Walter Kreucher commented "some technologies (Hybrid Electric) have penalties on the road that are not reflected on the tests used to determine CAFE compliance. ...If the Agencies want to provide adjustment factors for A/C and other 'Off-Cycle' conditions it must do so in both the positive and negative direction" (sic).³³⁸⁵ AVE commented that the agencies should use 5-cycle procedures rather than 2-cycle procedures, arguing that the 5-cycle model better demonstrates real-world driving conditions and would lead to a more simplified credit allocation system.³³⁸⁶ BorgWarner echoed those comments, stating that the 5-cycle test is more accurate than the 2-cycle test and would reduce the need for credit adjustments.³³⁸⁷ Jeremy Michalek commented that the fuel economy values the public sees reflected on vehicles for purchase (e.g., on the Monroney label or in new car advertising) is calculated from the 5-cycle test; updating the 2-cycle test to capture more of the vehicle's fuel efficiency factors would allow for better consistency and a more accurate fuel efficiency measure.³³⁸⁸ The Auto Alliance proposed that the EPA revise its methodology for calculating off-cycle improvements when using the 5-cycle methodology by subtracting the 2-cycle benefit from the 5-cycle benefit to ensure credits are calculated properly.³³⁸⁹

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The NPRM did not seek comment on revising test procedures to use 5-cycle test procedures in place of 2-cycle test procedures, either entirely or broadly. Such a change would require extensive assessment and analysis to consider how changes could be implemented and what standards might be maximum feasible for CAFE and appropriate and reasonable for CO₂ for new test procedures. There has been no analysis conducted to estimate the impacts of such a change. The agencies also did not propose to modify the off-cycle calculation for the 5-cycle measurement methodology as part of this rulemaking. Therefore, making these requested changes is outside the scope of this rulemaking.

2. National Zero Emissions Vehicle Concept

Although the agencies did not discuss or request comment on a National Zero Emissions Vehicle (NZEV) program concept, several organizations commented on that topic. Some discussed ideas from a task force that was formed by the governors of nine States who signed a memorandum of understanding (MOU) committing to undertake joint cooperative actions to build a robust market for ZEVs under their individual state programs. Collectively, these States have committed to having at least 3.3 million ZEVs operating on their roadways by 2025. ZEVs include battery-electric vehicles (BEVs), plug-in hybrid electric vehicles (PHEVs), and hydrogen fuel-cell electric vehicles (FCEVs). Comments on an NZEV concept were received from General Motors, CARB, Edison Electric Institute, Honda, NCAT, Workhorse Group, and Volvo.

General Motors offered comments supporting an NZEV program, stating that it continues to expect California to be the leader of the EV market but hopes a national effort will be put forth, making the U.S. a global leader in EV technology development and deployment.³³⁹⁰ General Motors stated it believes an NZEV program would further U.S. national security interests, make the U.S. more competitive with China, which already has an NZEV program, and reduce U.S. dependence on foreign petroleum. General Motors requested that EPA incentivize EV deployment, including providing credits for autonomous EVs and EVs that are used in rideshare programs.³³⁹¹ General Motors outlined their proposed NZEV program which would include increasing ZEV requirements annually, establishing credit banks for manufacturers based on national ZEV sales, and ZEV multipliers for vehicles over 5,250 lbs., autonomous vehicles using EV, and EVs in rideshare programs. General Motors also proposed that requirements would be revisited if EV battery cell were not available at the costs Argonne National Lab forecasts by 2025. General Motors also suggested implementing a Zero Emissions Task Force that would promote complementary policies. General Motors acknowledged that the NZEV program would have to be subject to acceleration or delay depending on how quickly technologies are incentivized like battery cost.

CARB recommended a national ZEV multiplier, stating that a national incentive would help ensure ZEVs and PHEVs were being produced for sale beyond the ten States that have ZEV

³³⁹⁰ General Motors, Detailed Comments, NHTSA-2018-0067-11858.

³³⁹¹ General Motors, Detailed Comments, NHTSA-2018-0067-11858.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

programs.³³⁹² The Edison Electric Institute supported increasing stringency of fuel economy and CO₂ standards and incorporating policies from ZEV States to create a “One National Program.”³³⁹³ Workhorse Group commented that a national ZEV mandate, where agencies progressively increase the mandated percentage of electric vehicles in every fleet, merits serious consideration by the agencies. They contended that an NZEV would have to work with the current State ZEV mandates and not preempt the progress already made.³³⁹⁴ Volvo, and Honda were proponents of incorporating ZEV standards into a national program. Volvo requested nationwide credits for ZEVs since there are 40 States without ZEV mandates.³³⁹⁵ Honda mentioned that incorporating California’s ZEV credits into the national program would reduce compliance costs for manufacturers while incentivizing technological development.³³⁹⁶ NCAT recommended in their comment that EPA provide enhanced credits for EVs, PHEVs, and FCVs that are more stringent than California (and other States) ZEV mandates, making the national program credits “additional” to state ZEV compliance credits.³³⁹⁷

Northeast States for Coordinated Air Use Management (NESCAUM) commented that an aggressive reduction in emissions will not occur without national ZEV standards which will drive development of advanced clean vehicle technologies.³³⁹⁸

The NPRM did not propose or request comment on an NZEV concept or program, as such, and establishing such a program would be outside the scope of this rulemaking. Such a concept would require thorough assessment and full rulemaking notice and comment. There are also policy questions about what the appropriate level of potential incentives should be and whether certain technologies should receive greater incentives than other technologies, and if so, on what basis and by what amounts. Also, for the CAFE program, incentives for technologies are almost entirely prescribed by statute, and there are questions about how the CAFE program could implement an NZEV program in alignment with EPCA and EISA. Therefore, the agencies have decided not to implement an NZEV program as part of this rulemaking.

3. CO₂ In-Use Requirements

Current in-use regulations outlined in 86.1845-04 provide flexibility in determining the applicable number of test vehicles per test group. Each large volume manufacturer is provided the flexibility to employ small volume sampling allowances for a limited number of total annual production units. In response to the NPRM, Volkswagen is proposing to modify 86.1845-04 to provide a separate, additional small volume sampling allowance allocation of annual production volume for a manufacturer’s plug-in hybrid vehicles. This additional allowance would only be

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

applicable through the 2025 model year and would only be applicable to CO₂ testing requirements under the in use regulations.

The basis for this flexibility is rooted in the continuing evolution and development of traction drive battery cell chemistries and battery management systems. This ongoing development is aimed at continuously improving such features as energy density, power, cost, and durability. As such, the engineering processes for understanding and quantifying long-term performance are still developing and subject to reevaluation as new chemistries are examined. Manufacturers such as Volkswagen have allocated significant capital in battery testing to ensure that performance is maintained for consumers and are also providing longer term battery warranty provisions.

Volkswagen believes that the targeted flexibility will provide additional time to continue evaluating chemistries and reduce administrative testing burdens for a very limited production allocation per manufacturer. This provision will further support plug-in hybrid technology development and deployment. Volkswagen proposed modifying 86.1845-04 table SO4-07 footnote 2, to read as follows:

² Total annual production of groups eligible for testing under small volume sampling plan is capped at a maximum of 14,999 vehicle 49 or 50 state annual sales, or a maximum of 4,500 vehicle California only sales per model year, per large volume manufacturer. Through model year 2025, a separate total annual production of plug-in hybrid electric vehicle groups shall be eligible for testing under small volume sampling plan as described above. This allocation shall only be applicable to exhaust CO₂ emission standards under this subpart.³³⁹⁹

Regarding comments from VW on CO₂ in-use requirements, EPA did not consider the change recommended by VW in the proposal and is not finalizing such a change. EPA believes the current program provides enough flexibility. EPA's general approach for this final rule is also to avoid providing incentives or other unique flexibilities to specific technologies.

F. Medium- and Heavy-Duty Fuel Efficiency Technical Amendments

NHTSA proposed in the NPRM to make minor technical revisions to correct typographical mistakes and improper references adopted in the agency's 2016 Phase 2 medium- and heavy-duty fuel efficiency rule.³⁴⁰⁰ The proposed changes were as follows:

- NHTSA heavy-duty vehicles and engine fuel consumption credit equations. In each credit equation in 49 CFR 535.7, the minus-sign in each multiplication factor was omitted in the final version of the rule sent to the *Federal Register*. For example, the credit equation in Part 535.7(b)(1) should be specified as, Total MY Fleet FCC

³³⁹⁹ See EPA-HQ-OAR-2018-0283-5689-A1, p.32.

³⁴⁰⁰ 81 FR 73478 (Oct. 25, 2016).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(gallons) = (Std - Act) × (Volume) × (UL) × (10-2) instead of (102), as currently exists. NHTSA proposed to correct these omissions.

- The CO₂ to gasoline conversion factor: In 49 CFR 535.6(a)(4)(ii) and (d)(5)(ii), NHTSA provides the methodology and equations for converting the CO₂ FELs/FCLs for heavy-duty pickups and vans (gram per mile) and for engines (grams per hp-hr) to their gallon-of-gasoline equivalence. In each equation, NHTSA proposed to correct the conversion factor to 8,887 grams per gallon of gasoline fuel instead of a factor of 8,877 as currently specified.
- Curb weight definition: In 49 CFR 523.2, the reference in the definition for curb weight is incorrect. NHTSA proposed to correct the definition to incorporate a reference to 40 CFR 86.1803 instead of 49 CFR 571.3.

No public comments were received in response to NHTSA's proposed technical corrections. Therefore, NHTSA is finalizing these amendments and incorporating them into its heavy-duty regulations.

X. Regulatory Notices and Analyses

A. Executive Order 12866, Executive Order 13563

Executive Order 12866, "Regulatory Planning and Review" (58 FR 51735, Oct. 4, 1993), as amended by Executive Order 13563, "Improving Regulation and Regulatory Review" (76 FR 3821, Jan. 21, 2011), provides for making determinations whether a regulatory action is "significant" and therefore subject to the Office of Management and Budget (OMB) review and to the requirements of the Executive Order. One comment requested that the agencies provide "a far more robust cost/benefit analysis as required by Executive Order (EO) 12866 and Office of Management and Budget Circular A-4."³⁴⁰¹ The NPRM and this final rule satisfy the requirements of Executive Order 12866, "Regulatory Planning and Review" (58 FR 51735, Oct. 4, 1993), as amended by Executive Order 13563, "Improving Regulation and Regulatory Review" (76 FR 3821, Jan. 21, 2011). Under these Executive Orders, this action is an "economically significant regulatory action" because it is likely to have an annual effect on the economy of \$100 million or more. Accordingly, EPA and NHTSA submitted this action to the OMB for review and any changes made in response to OMB recommendations have been documented in the docket for this action. The benefits and costs of this proposal are described

³⁴⁰¹ See Anonymous Comment, Docket No. EPA-HQ-OAR-2018-0283-3896, at 4-5 (footnote and citation omitted).

As an example, the comment critiqued the NPRM's discussion of the "diminishing returns" of fuel economy benefits, alleging that the discussion "is not backed by reference to data or studies regarding how this conclusion was made." *Id.* at 5. Contrary to the comment's allegation, the conclusion is supported by the analysis from U.S. Energy Information Administration's (EIA's) Annual Energy Outlook (AEO) that was cited in the discussion. *Id.* As noted in the NPRM, the EIA—the statistical and analytical agency within the U.S. Department of Energy (DOE)—is the nation's premier source of energy information, and every fuel economy rulemaking since 2002 (and every joint CAFE and CO₂ rulemaking since 2009) has applied fuel price projections from EIA's AEO. *Id.* at 42992 n.24.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

above and in the Final Regulatory Impact Analysis (FRIA), which is located in the docket and on the agencies' websites.

B. DOT Regulatory Policies and Procedures

The rule is also significant within the meaning of the Department of Transportation's Regulatory Policies and Procedures. The benefits and costs of this proposal are described above and in the FRIA, which is located in the docket and on NHTSA's website.

C. Executive Order 13771 (Reducing Regulation and Controlling Regulatory Costs)

This rule is an E.O. 13771 deregulatory action. Per OMB Memorandum M-17-21, because this rule is deregulatory, it is not required to be offset by two deregulatory actions, as one comment suggested.³⁴⁰² Details on the estimated cost savings of this proposed rule can be found in FRIA, which is located in the docket and on the agencies' websites.

D. Executive Order 13211 (Energy Effects)

Executive Order 13211 applies to any rule that: (1) is determined to be economically significant as defined under E.O. 12866, and is likely to have a significant adverse effect on the supply, distribution, or use of energy; or (2) that is designated by the Administrator of the Office of Information and Regulatory Affairs as a significant energy action. If the regulatory action meets either criterion, the agencies must evaluate the adverse energy effects of the rule and explain why the regulation is preferable to other potentially effective and reasonably feasible alternatives considered.

The rule establishes passenger car and light truck fuel economy standards and tailpipe carbon dioxide and related emissions standards. An evaluation of energy effects of the action and reasonably feasible alternatives considered is provided in NHTSA's EIS and in the FRIA. To the extent that EPA's CO₂ standards are substantially related to fuel economy and, accordingly, petroleum consumption, the EIS and FRIA analyses also provide an estimate of impacts of EPA's rule.

E. Environmental Considerations

1. National Environmental Policy Act (NEPA)

Concurrently with this final rule, NHTSA is releasing a Final Environmental Impact Statement (FEIS), pursuant to the National Environmental Policy Act, 42 U.S.C. 4321-4347, and implementing regulations issued by the Council on Environmental Quality (CEQ), 40 CFR part 1500, and NHTSA, 49 CFR part 520. NHTSA prepared the FEIS to analyze and disclose the potential environmental impacts of the proposed CAFE standards and a range of alternatives. The FEIS analyzes direct, indirect, and cumulative impacts and analyzes impacts in proportion to

³⁴⁰² Anonymous Comment, Docket No. EPA-HQ-OAR-2018-0283-3896, at 8.

their significance. It describes potential environmental impacts to a variety of resources, including fuel and energy use, air quality, climate, land use and development, hazardous materials and regulated wastes, historical and cultural resources, noise, and environmental justice. The FEIS also describes how climate change resulting from global carbon emissions (including CO₂ emissions attributable to the U.S. light duty transportation sector under the alternatives considered) could affect certain key natural and human resources. Resource areas are assessed qualitatively and quantitatively, as appropriate, in the FEIS.

Some commenters provided feedback on the “flaws” they identified in the CAFE model, concluding that because it played a significant role in modeling for the DEIS, the DEIS itself was flawed and should be withdrawn and reissued.³⁴⁰³ The agencies address the comments regarding the CAFE model above in this preamble and in the FRIA. Ultimately, the findings on potential environmental impacts presented in the FEIS are of the same level of intensity and significance as those presented in the DEIS. While in some cases, the directionality of potential air quality emissions changed, the overall impact was generally small. NHTSA concludes that the CAFE model results, as used in the FEIS, do not result in the FEIS providing significant new information for the decisionmaker or the public compared to the DEIS.³⁴⁰⁴ NHTSA therefore concludes that a supplemental DEIS is not required.

NHTSA also performed a national-scale photochemical air quality modeling and health benefit assessment for the FEIS; it is included as Appendix E. The purpose of this assessment was to use air quality modeling and health-related benefits analysis tools to examine the potential air quality-related consequences of the alternatives considered in its Draft Environmental Impact Statement (DEIS). In a comment on the DEIS, the South Coast Air Quality Management District stated that performing the photochemical modeling for the FEIS “comes too late for the public to be able to comment on that analysis,” and that the EIS must be recirculated to allow such public comment.³⁴⁰⁵ However, NHTSA publicly stated its intent to conduct the analysis as part of the FEIS in its scoping notice published on July 26, 2017.³⁴⁰⁶ The agency noted that this approach was consistent with past practice and resulted from the substantial time required to complete such an analysis. NHTSA also announced that, due to the substantial lead time required, the analysis would be based on the modeling of the alternatives presented in the DEIS, not of the alternatives as presented in the FEIS. NHTSA received no public comments in response to the scoping notice addressing this analytical approach, and the agency proceeded accordingly.

³⁴⁰³ States of California, Connecticut, Delaware, Hawaii, Iowa, Illinois, Maine, Maryland, Minnesota, North Carolina, New Jersey, New Mexico, New York, Oregon, Rhode Island, Vermont, and Washington; the Commonwealths of Massachusetts, Pennsylvania, and Virginia; the District of Columbia; and the Cities of Los Angeles, New York, Oakland, San Francisco, and San Jose (“California *et al.*—Detailed NEPA Comments”), Docket No. NHTSA-2017-0069-0625, at 6-11; Environmental Defense Fund, Docket No. NHTSA-2018-0067-11996, at 3-4; and Center for Biological Diversity, *et al.*, Docket No. NHTSA-2018-0067-12123, at 19.

³⁴⁰⁴ 40 CFR 1502.9(c)(1)(ii).

³⁴⁰⁵ South Coast Air Quality Management District, Docket No. NHTSA-2018-0067-5666, at 10. *See also* North Carolina Department of Environmental Quality, Docket No. NHTSA-2018-0067-12025, at 35-37.

³⁴⁰⁶ NHTSA, “Notice of Intent to Prepare an Environmental Impact Statement for Model Year 2022–2025 Corporate Average Fuel Economy Standards,” 82 FR 34740, 34743 fn. 15 (Jul. 26, 2017).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Furthermore, while photochemical modeling provides spatial and temporal detail for estimating changes in ambient levels of air pollutants and their associated impacts on human health and welfare, the analysis affirms the estimates that appear in the EIS and does not provide significant new information for the decisionmaker or the public. For these reasons, NHTSA concludes that inclusion of the photochemical modeling and health benefit assessment in the FEIS is appropriate, and recirculation of the EIS is not required.

NHTSA has considered the information contained in the FEIS in making the final decision described in this final rule.³⁴⁰⁷ This preamble and final rule constitute NHTSA's Record of Decision (ROD) under 40 CFR 1505.2 for its promulgation of CAFE standards for MYs 2021-2026. NHTSA has authority to issue its FEIS and ROD simultaneously pursuant to 49 U.S.C. 304a(b) and U.S. Department of Transportation, Office of Transportation Policy, *Guidance on the Use of Combined Final Environmental Impact Statements/Records of Decision and Errata Sheets in National Environmental Policy Act Reviews* (April 25, 2019).³⁴⁰⁸ NHTSA has determined that neither the statutory criteria nor practicability considerations preclude simultaneous issuance.

As required by the CEQ regulations,³⁴⁰⁹ this final rule (as the ROD) sets forth the following: (1) The agency's decision (Sections V and VIII above); (2) alternatives considered by NHTSA in reaching its decision, including the environmentally preferable alternative (Sections V, VII, and VIII above); (3) the factors balanced by NHTSA in making its decision, including essential considerations of national policy (Section VIII.B above); (4) how these factors and considerations entered into its decision (Section VIII.B above); and (5) the agency's preferences among alternatives based on relevant factors, including economic and technical considerations and agency statutory missions (Section VIII.B.4 above). This section also briefly addresses mitigation³⁴¹⁰ and whether all practicable means to avoid or minimize environmental harm from the alternative selected have been adopted.

In the DEIS and in the FEIS, the agency identified a Preferred Alternative. In the DEIS, the Preferred Alternative was identified as Alternative 1 (0.0 Percent Annual Increase in Fuel Economy, MYs 2021-2026), which were the standards the agency proposed in the NPRM. In the FEIS, the Preferred Alternative was identified as Alternative 3 (1.5 Percent Annual Increase in Fuel Economy, MYs 2021-2026). As the FEIS notes, under the Preferred Alternative, on an mpg basis, the estimated annual increases in the average required fuel economy levels between MYs 2021 and 2026 is 1.5 percent for both passenger cars and light trucks.³⁴¹¹ After carefully

³⁴⁰⁷ The FEIS is available for review in the public docket for this action and in Docket No. NHTSA-2017-0069.

³⁴⁰⁸ The guidance is available at <https://www.transportation.gov/sites/dot.gov/files/docs/mission/transportation-policy/permittingcenter/337371/feis-rod-guidance-final-04302019.pdf>.

³⁴⁰⁹ 40 CFR 1505.2.

³⁴¹⁰ See 40 CFR 1508.20(b) ("Mitigation includes ... (b) Minimizing impacts by limiting the degree or magnitude of the action and its implementation...")

³⁴¹¹ Because the standards are attribute-based, average required fuel economy levels, and therefore rates of increase in those average mpg values, depend on the future composition of the fleet, which is uncertain and subject to

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

reviewing and analyzing all of the information in the public record, the FEIS, and comments submitted on the DEIS and the NPRM, NHTSA has decided to finalize the Preferred Alternative described in the FEIS for the reasons described in this ROD.

NHTSA has considered environmental considerations as part of its balancing of the statutory factors to set maximum feasible fuel economy standards. As a result, the agency has limited the degree or magnitude of the action as appropriate in light of its statutory responsibilities. NHTSA's authority to promulgate fuel economy standards does not allow it to regulate criteria pollutants from vehicles or refineries, nor can NHTSA regulate other factors affecting those emissions, such as driving habits. Consequently, NHTSA must set CAFE standards but is unable to take further steps to mitigate the impacts of these standards. Chapter 9 of the FEIS provides a further discussion of mitigation measures in the context of NEPA.

One commenter states that NHTSA, at a minimum, "must include a thorough discussion of all reasonable mitigation measures and detail the appropriate agencies that could implement such measures."³⁴¹² As examples, the commenter listed: "creating tax breaks for transit and biking, expanding transportation demand management programs for federal employees, implementing a social marketing campaign regarding VMT reduction, increasing dedicated funding for transit and active modes, requiring VMT as a performance measure for federal funding, and providing NEPA guidance on evaluating VMT impacts of federal projects." Each of the examples listed is beyond NHTSA's statutory authority. Furthermore, documenting the myriad measures that could reduce VMT or address criteria pollutant or carbon dioxide emissions would provide no added benefit to the decisionmaker or the public. Each of these actions requires their own extensive cost-benefit analysis, are beyond the purview of this action, and are beyond the legal responsibility of NHTSA. NHTSA concludes that the commenter's request is beyond the bounds of NEPA's "rule of reason."³⁴¹³

Another commenter disputes NHTSA's conclusion that it lacks statutory authority to mitigate the impacts of its CAFE standards. Specifically, the commenter cites to its very authority to set fuel economy standards: "It is axiomatic that fuel efficiency standards set at levels of the No Action Alternative or at more stringent levels would eliminate the additional pollution created by the proposed freeze."³⁴¹⁴ This, however, mischaracterizes mitigation as nothing more than a choice among alternatives. NHTSA is already considering a range of reasonable alternatives and has concluded that alternatives more stringent than the No Action Alternative are beyond reasonable. Furthermore, NHTSA disputes that more stringent fuel economy standards will axiomatically lead to lower levels of criteria pollutant emissions. In fact,

change. When NHTSA describes a percent increase in stringency, we mean in terms of shifts in the *footprint functions* that form the basis for the *actual* CAFE standards (as in, on a gallon per mile basis, the CAFE standards change by a given percentage from one model year to the next).

³⁴¹² California *et al.*—Detailed NEPA Comments, Docket No. NHTSA-2017-0069-0625, at 31.

³⁴¹³ Dep't of Transp. v. Pub. Citizen, 541 U.S. 752, 772 (2004).

³⁴¹⁴ Center for Biological Diversity, *et al.*, Docket No. NHTSA-2018-0067-12123, at 55-56.

because of the rebound effect, higher levels of stringency may result in higher VMT, which may result in criteria pollutant emission increases.

The North Carolina Department of Environmental Quality commented that the proposed changes to the CAFE standards could undermine the integrity of many of the assumptions in various NEPA documents across the United States, in part because EPA required the use of the MOVES2014 model (or a subsequent revision) for transportation conformity determinations.³⁴¹⁵ That version of MOVES incorporates CAFE and CO₂ standards based on the agencies' actions in 2012 and does not reflect the actions being finalized in this rule. The implication of the commenter's assertion, however, is that neither NHTSA nor EPA could take any regulatory action regarding CAFE or CO₂ standards, regardless of whether such action was to increase or decrease such standards. Clearly neither agency can be paralyzed from undertaking its statutory obligations because of the independent NEPA obligations related to other ongoing Federal actions. For those actions, responsible officials may need to assess whether this final rule triggers the need for a supplemental NEPA document. However, it is not unique for Federal agencies to take actions or for new information to become available that affects the underlying inputs in models, such as EPA's MOVES model, on which NEPA and conformity analyses rely. Over time, those models will be updated to reflect these actions and information. EPA is responsible for approving the availability of models for the use in State implementation plans and transportation conformity analyses. EPA will evaluate and address, as appropriate, the impact of this action on future SIP approval actions. Currently approved emission factor models remain approved for SIPs and transportation conformity analyses, and EPA will work with DOT on the appropriate implementation of Federal requirements based on current and available information.

2. Clean Air Act (CAA) as Applied to NHTSA's Action

The CAA (42 U.S.C. 7401 et seq.) is the primary Federal legislation that addresses air quality. Under the authority of the CAA and subsequent amendments, EPA has established National Ambient Air Quality Standards (NAAQS) for six criteria pollutants, which are specifically identified pollutants that have recognized adverse effects on ambient air quality and that can accumulate in the atmosphere as a result of human activity. EPA is required to review each NAAQS every five years and to revise those standards as may be appropriate considering new scientific information.

The air quality of a geographic region is usually assessed by comparing the levels of criteria air pollutants found in the ambient air to the levels established by the NAAQS (taking into account, as well, the other elements of a NAAQS: averaging time, form, and indicator). Concentrations of criteria pollutants within the air mass of a region are measured in parts of a pollutant per million parts (ppm) of air or in micrograms of a pollutant per cubic meter ($\mu\text{g}/\text{m}^3$) of air present in repeated air samples taken at designated monitoring locations using specified

³⁴¹⁵ North Carolina Department of Environmental Quality, Docket No. NHTSA-2018-0067-12025, at 37. *See also* Southern Environmental Law Center, EPA-HQ-OAR-2018-0283-0887, at 2-4.

types of monitors. These ambient concentrations of each criteria pollutant are compared to the levels, averaging time, and form specified by the NAAQS in order to assess whether the region's air quality is in attainment with the NAAQS.

When the measured concentrations of a criteria pollutant within a geographic region are below those permitted by the NAAQS, EPA designates the region as an attainment area for that pollutant, while regions where concentrations of criteria pollutants exceed Federal standards are called nonattainment areas. Former nonattainment areas that are now in compliance with the NAAQS are designated as maintenance areas. Each State with a nonattainment area is required to develop and implement a State Implementation Plan (SIP) documenting how the region will reach attainment levels within time periods specified in the CAA. For maintenance areas, the SIP must document how the State intends to maintain compliance with the NAAQS. When EPA revises a NAAQS, each State must revise its SIP to address how it plans to attain the new standard.

No Federal agency may “engage in, support in any way or provide financial assistance for, license or permit, or approve” any activity that does not “conform” to a SIP or Federal Implementation Plan after EPA has approved or promulgated it.³⁴¹⁶ Further, no Federal agency may “approve, accept, or fund” any transportation plan, program, or project developed pursuant to title 23 or chapter 53 of title 49, U.S.C., unless the plan, program, or project has been found to “conform” to any applicable implementation plan in effect.³⁴¹⁷ The purpose of these conformity requirements is to ensure that Federally sponsored or conducted activities do not interfere with meeting the emissions targets in SIPs, do not cause or contribute to new violations of the NAAQS, and do not impede the ability of a State to attain or maintain the NAAQS or delay any interim milestones. EPA has issued two sets of regulations to implement the conformity requirements:

(1) The Transportation Conformity Rule³⁴¹⁸ applies to transportation plans, programs, and projects that are developed, funded, or approved under title 23 or chapter 53 of title 49, U.S.C.

(2) The General Conformity Rule³⁴¹⁹ applies to all other federal actions not covered under transportation conformity. The General Conformity Rule establishes emissions thresholds, or *de minimis* levels, for use in evaluating the conformity of an action that results in emissions increases.³⁴²⁰ If the net increases of direct and indirect emissions are lower than these thresholds, then the project is presumed to conform and no further conformity evaluation is required. If the net increases of direct and indirect emissions exceed any of these thresholds, and the action is not otherwise exempt, then a conformity determination is required. The conformity determination

can entail air quality modeling studies, consultation with EPA and state air quality agencies, and commitments to revise the SIP or to implement measures to mitigate air quality impacts.

The CAFE standards and associated program activities are not developed, funded, or approved under title 23 or chapter 53 of title 49, United States Code. Accordingly, this action and associated program activities are not subject to the Transportation Conformity Rule. Under the General Conformity Rule, a conformity determination is required where a Federal action would result in total direct and indirect emissions of a criteria pollutant or precursor originating in nonattainment or maintenance areas equaling or exceeding the rates specified in 40 CFR 93.153(b)(1) and (2). As explained below, NHTSA's action results in neither direct nor indirect emissions as defined in 40 CFR 93.152.

The General Conformity Rule defines direct emissions as "those emissions of a criteria pollutant or its precursors that are caused or initiated by the Federal action and originate in a nonattainment or maintenance area and occur at the same time and place as the action and are reasonably foreseeable."³⁴²¹ Because NHTSA's action would set fuel economy standards for light duty vehicles, it would cause no direct emissions consistent with the meaning of the General Conformity Rule.³⁴²²

Indirect emissions under the General Conformity Rule are "those emissions of a criteria pollutant or its precursors (1) that are caused or initiated by the federal action and originate in the same nonattainment or maintenance area but occur at a different time or place as the action; (2) that are reasonably foreseeable; (3) that the agency can practically control; and (4) for which the agency has continuing program responsibility."³⁴²³ Each element of the definition must be met to qualify as indirect emissions. NHTSA has determined that, for purposes of general conformity, emissions that may result from its final fuel economy standards would not be caused by NHTSA's action, but rather would occur because of subsequent activities the agency cannot practically control. "[E]ven if a Federal licensing, rulemaking, or other approving action is a required initial step for a subsequent activity that causes emissions, such initial steps do not mean that a Federal agency can practically control any resulting emissions."³⁴²⁴

As the CAFE program uses performance-based standards, NHTSA cannot control the technologies vehicle manufacturers use to improve the fuel economy of passenger cars and light trucks. Furthermore, NHTSA cannot control consumer purchasing (which affects average achieved fleetwide fuel economy) and driving behavior (i.e., operation of motor vehicles, as measured by VMT). It is the combination of fuel economy technologies, consumer purchasing,

³⁴²¹ 40 CFR 93.152.

³⁴²² *Dep't of Transp. v. Pub. Citizen*, 541 U.S. at 772 ("[T]he emissions from the Mexican trucks are not 'direct' because they will not occur at the same time or at the same place as the promulgation of the regulations."). NHTSA's action is to establish fuel economy standards for MY 2021–2026 passenger car and light trucks; any emissions increases would occur in a different place and well after promulgation of the final rule.

³⁴²³ 40 CFR 93.152.

³⁴²⁴ 40 CFR 93.152.

and driving behavior that results in criteria pollutant or precursor emissions. For purposes of analyzing the environmental impacts of the alternatives considered here and under NEPA, NHTSA has made assumptions regarding all of these factors. The agency's FEIS predicts that increases in air toxic and criteria pollutants would occur in some nonattainment areas under certain alternatives. However, the standards and alternatives do not mandate specific manufacturer decisions, consumer purchasing, or driver behavior, and NHTSA cannot practically control any of them.³⁴²⁵

In addition, NHTSA does not have the statutory authority to control the actual VMT by drivers. As the extent of emissions is directly dependent on the operation of motor vehicles, changes in any emissions that result from NHTSA's CAFE standards are not changes the agency can practically control or for which the agency has continuing program responsibility. Therefore, the final CAFE standards and alternative standards considered by NHTSA would not cause indirect emissions under the General Conformity Rule, and a general conformity determination is not required.

As this analysis was presented in the NPRM, some commenters disagreed with NHTSA's conclusion. One commenter cited two reasons for concluding that the General Conformity Rule applies to NHTSA's action.³⁴²⁶ First, the commenter argues that NHTSA used "inappropriate modeling" in its analysis. However, this is irrelevant to the agency's analysis, which is based on the Federal regulations and the applicable case law. Second, the commenter asserts that NHTSA "cannot have it both ways" by alleging that it cannot control the technologies that automobile manufacturers would use or consumer purchasing behavior, yet justifies its rulemakings based on consumer purchasing and emissions implications.^{3427, 3428} The rulemaking analysis presents a feasible pathway for manufacturers to comply with the rules, based on a series of assumptions about consumer behavior; it is not sufficiently foreseeable to trigger application of the General Conformity Rule. Furthermore, NHTSA cannot directly control these behaviors, and the chain of causation is too attenuated to be responsible for the resulting emissions. Another commenter stated that NHTSA has continuing program responsibility for motor vehicle criteria pollutant emissions because it "retain[s] authority to revise [its] standards in a way that affects future emission levels."³⁴²⁹ However, NHTSA disagrees with this assertion. First, the agency does not have statutory authority to regulate criteria pollutant emissions from motor vehicles. Second, the

³⁴²⁵ See, e.g., *Dep't of Transp. v. Pub. Citizen*, 541 U.S. 752, 772-73 (2004); *S. Coast Air Quality Mgmt. Dist. v. Fed. Energy Regulatory Comm'n*, 621 F.3d 1085, 1101 (9th Cir. 2010).

³⁴²⁶ *California et. al.*—Detailed NEPA Comments, Docket No. NHTSA-2017-0069-0625, at 21-22.

³⁴²⁷ The commenter also quotes *CBD v. NHTSA*, 538 F.3d at 1217, for the proposition that NHTSA's regulations are the proximate cause of the emissions because they allow particular fuel economy levels that "translate directly into particular tailpipe emissions." However, that quote was referencing carbon dioxide emissions, which are predictable based on fuel used. NHTSA can directly regulate fuel economy for passenger cars and light trucks. On the other hand, criteria pollutant emissions are more significantly impacted by VMT, technology choices, and other factors that are not directly within the control of NHTSA.

³⁴²⁸ See also Joint Submission from the States of California *et al.* and the Cities of Oakland *et al.*, Docket No. NHTSA-2018-0067-11735, at 35.

³⁴²⁹ *Id.*

fact that NHTSA could establish CAFE standards for separate, future motor vehicles does not establish continuing program responsibility over emissions that could result from the vehicles regulated by this action.

NHTSA and EPA further discuss their obligations under the General Conformity Rule, and further address comments received, in Section VI.6.D.3 above.

3. National Historic Preservation Act (NHPA)

The NHPA (54 U.S.C. 300101 *et seq.*) sets forth government policy and procedures regarding “historic properties”—that is, districts, sites, buildings, structures, and objects included on or eligible for the National Register of Historic Places. Section 106 of the NHPA requires Federal agencies to “take into account” the effects of their actions on historic properties.³⁴³⁰ In the NPRM, the agencies concluded that the NHPA is not applicable to this rulemaking because the promulgation of CAFE and CO₂ emissions standards for light duty vehicles is not the type of activity that has the potential to cause effects on historic properties.

Two commenters wrote that “[c]limate change and air pollution imperil historic properties throughout the country via direct degradation, sea level rise, fire, flood, and other forms of harm.” Therefore, the commenters concluded that NHTSA and EPA must consult with the relevant Federal and State authorities and fully disclose any impacts to historic properties.³⁴³¹ However, as this final rule establishes CAFE and CO₂ standards that increase each year for MYs 2021–2026, this action will result in reductions in climate change-related impacts and most air pollutants compared to the absence of regulation. Furthermore, any impacts to particular historic properties that could be related to emissions changes associated with this rulemaking are not reasonably certain to occur, would be *de minimis* in their level of impact if they did occur, and are too attenuated to be attributed directly to this action. (*See also* Section X.E.6 below.) There is no evidence that the changes in air pollution or CO₂ emissions associated with this rulemaking, in and of themselves, would alter the characteristics of a historic property qualifying it for inclusion in or eligibility for the National Register.³⁴³² Nevertheless, NHTSA includes a brief, qualitative discussion of the impacts of the alternatives on historical and cultural resources in Section 7.3 of the FEIS. For the foregoing reasons, the agencies continue to conclude that any potential impacts have been accounted for in the associated analyses of this rulemaking and that no consultation is required under the NHPA.

4. Fish and Wildlife Conservation Act (FWCA)

The FWCA (16 U.S.C. 2901 *et seq.*) provides financial and technical assistance to States for the development, revision, and implementation of conservation plans and programs for

³⁴³⁰ Section 106 is now codified at 54 U.S.C. 306108. Implementing regulations for the Section 106 process are located at 36 CFR part 800.

³⁴³¹ CARB, Docket No. NHTSA-2018-0067-11873, at 411; California *et. al.*—Detailed NEPA Comments, Docket No. NHTSA-2017-0069-0625, at 30.

³⁴³² 36 CFR 800.16(i).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

nongame fish and wildlife. In addition, the Act encourages all Federal departments and agencies to utilize their statutory and administrative authorities to conserve and to promote conservation of nongame fish and wildlife and their habitats. The agencies conclude that the FWCA is not applicable to this final rule because this rulemaking does not involve the conservation of nongame fish and wildlife and their habitats. NHTSA has, however, conducted a qualitative review in its FEIS of the related direct, indirect, and cumulative impacts, positive or negative, of the alternatives on potentially affected resources, including nongame fish and wildlife and their habitats.

5. Coastal Zone Management Act (CZMA)

The Coastal Zone Management Act (16 U.S.C. 1451 *et seq.*) provides for the preservation, protection, development, and (where possible) restoration and enhancement of the Nation's coastal zone resources. Under the statute, States are provided with funds and technical assistance in developing coastal zone management programs. Each participating State must submit its program to the Secretary of Commerce for approval. Once the program has been approved, any activity of a Federal agency, either within or outside of the coastal zone, that affects any land or water use or natural resource of the coastal zone must be carried out in a manner that is consistent, to the maximum extent practicable, with the enforceable policies of the State's program.³⁴³³

In the NPRM, the agencies concluded that the CZMA is not applicable to this rulemaking because this rulemaking does not involve an activity within, or outside of, the Nation's coastal zones that affects any land or water use or natural resource of the coastal zone. CARB commented that California's coast is vulnerable to sea level rise from climate change and that the proposal would exacerbate that threat. Therefore, the commenter claimed that the proposal violated California's policies and obligations in its management program to preserve, protect, and enhance its coastline.³⁴³⁴ However, in its FEIS, NHTSA estimates that the sea-level rise in 2100 associated with Alternative 1 (0 percent annual average increase for both passenger cars and light trucks for MYs 2021–2026), the least stringent alternative considered, would be 0.7 mm. Such a level is too small to have any meaningful impact on land or water use or a natural resource of the coastal zone. Furthermore, as this final rule establishes CAFE and CO₂ standards that increase each year for MYs 2021–2026, this action will result in reductions in sea level rise resulting from climate change compared to the absence of regulation. Therefore, the agencies continue to conclude that the CZMA is not applicable to this rulemaking. NHTSA has, however, conducted a qualitative review in its FEIS of the related direct, indirect, and cumulative impacts, positive or negative, of the alternatives on potentially affected resources, including coastal zones.

³⁴³³ 16 U.S.C. 1456(c)(1)(A).

³⁴³⁴ CARB, Docket No. NHTSA-2018-0067-11873, at 411.

6. Endangered Species Act (ESA)

Under Section 7(a)(2) of the Endangered Species Act (ESA), Federal agencies must ensure that actions they authorize, fund, or carry out are “not likely to jeopardize the continued existence” of any Federally listed threatened or endangered species (collectively, “listed species”) or result in the destruction or adverse modification of the designated critical habitat of these species.³⁴³⁵ In general, if a Federal agency determines that an agency action may affect a listed species or designated critical habitat, it must initiate consultation with the appropriate Service — the U.S. Fish and Wildlife Service (FWS) of the Department of the Interior (DOI) and/or the National Oceanic and Atmospheric Administration’s National Marine Fisheries Service (NMFS) of the Department of Commerce (together, “the Services”), depending on the species involved — in order to ensure that the action is not likely to jeopardize the species or destroy or adversely modify designated critical habitat.³⁴³⁶ Under this standard, the Federal agency taking action evaluates the possible effects of its action and determines whether to initiate consultation.³⁴³⁷

In the NPRM, the agencies noted that they had considered the effects of the proposed standards and alternatives in light of applicable ESA regulations, case law, and guidance to determine what, if any, impact there might be to listed species or designated critical habitat. The agencies also considered the discussion in the DEIS, where NHTSA incorporated by reference its response to a public comment on page 9-101 of the MY 2017–2025 CAFE Standards Final EIS.³⁴³⁸ Based on that assessment, the agencies determined that the actions of setting CAFE and CO₂ emissions standards did not require consultation under Section 7(a)(2) of the ESA. Accordingly, the agencies wrote that they had concluded their review of this action under Section 7 of the ESA.

Several commenters disagreed with the agencies’ assessment. In general, commenters stated that the agencies’ proposed action would increase emissions of CO₂ and criteria air pollutants (e.g., nitrogen oxide [NO_x] and sulfur dioxide [SO₂]³⁴³⁹), that these emissions would have direct or indirect (i.e., through climate change) impacts on listed species and critical

³⁴³⁵ 16 U.S.C. 1536(a)(2).

³⁴³⁶ See 50 CFR 402.14.

³⁴³⁷ See 50 CFR 402.14(a) (“Each Federal agency shall review its actions at the earliest possible time to determine whether any action may affect listed species or critical habitat.”)

³⁴³⁸ For the MY 2017–2025 CAFE rulemaking, NHTSA concluded that a Section 7(a)(2) consultation was not required because any potential for a specific impact on particular listed species and their habitats associated with emission changes achieved by that rulemaking were too uncertain and remote to trigger the threshold for such a consultation. In the Draft EIS, NHTSA wrote that this conclusion, based on the discussion and analysis cited, applied to the current rulemaking.

³⁴³⁹ In fact, in Section 4.2.1.1 of NHTSA’s FEIS, the agency reports that any of the action alternatives would result in decreased emissions of sulfur dioxide in 2025, 2035, and 2050 compared to the No Action Alternative.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

habitats, that the threshold for a finding of “may affect” is extremely low, and that the agencies therefore have a duty to consult with the Services under the ESA.³⁴⁴⁰

In light of these comments, the agencies re-evaluated their obligations under the ESA and applicable regulations, case law, and guidance. Ultimately, for the following reasons, the agencies arrive at the same conclusion. Although there is a general association between the actions undertaken in this final rule and environmental impacts described in this preamble and the FEIS, the agencies’ actions result in no effects on listed species or designated critical habitat and therefore do not require consultation under Section 7(a)(2) of the ESA. Furthermore, the agencies lack sufficient discretion or control to bring these actions under the consultation requirement of the ESA. The agencies’ review under the ESA is concluded.

a) The Agencies’ Actions Have No Effects on Listed Species or Critical Habitat and Do Not Trigger ESA Consultation

Commenters have stated that CO₂ and criteria air pollutant emissions are relevant to Section 7(a)(2) consultation because of the potential impacts of climate change or the pollutants themselves on listed species or critical habitat. The agencies have considered the potential impacts of this action to listed species or designated critical habitat of these species and concludes that any such impacts cannot be attributed to the agencies’ actions (e.g., they are too uncertain and attenuated). Because the agencies conclude there are “no effects,” Section 7(a)(2) consultation is not required. The agencies base this conclusion both on the language of the Section 7(a)(2) implementing regulations and on the long history of actions and guidance provided by DOI.

The Section 7(a)(2) implementing regulations require consultation if a Federal agency determines its action “may affect” listed species or critical habitat.³⁴⁴¹ The recently revised regulations define “effects of the action” as “all consequences to listed species or critical habitat that are caused by the proposed action, including the consequences of other activities that are caused by the proposed action. A consequence is caused by the proposed action if it would not

³⁴⁴⁰ See Center for Biological Diversity, Earthjustice, Natural Resources Defense Council, and Sierra Club, Docket Nos. NHTSA-2017-0069-0605 and NHTSA-2018-0067-12127; Center for Biological Diversity, Sierra Club, and Public Citizen, Inc., Docket No. NHTSA-2018-0067-12378; Center for Biological Diversity, Earthjustice, Environmental Law and Policy Center, Natural Resources Defense Council, Public Citizen, Inc., Safe Climate Campaign, Sierra Club, Southern Environmental Law Center, and Union of Concerned Scientists, Docket No. NHTSA-2018-0067-12123, at 69; States of California, Connecticut, Delaware, Hawaii, Iowa, Illinois, Maine, Maryland, Minnesota, New Jersey, New Mexico, New York, North Carolina, Oregon, Rhode Island, Vermont, and Washington, the Commonwealths of Massachusetts, Pennsylvania, and Virginia, the District of Columbia, and the Cities of Los Angeles, New York, Oakland, San Francisco, and San Jose, Docket Nos. NHTSA-2018-0067-11735, at 47-48; and California Air Resources Board, Docket Nos. NHTSA-2018-0067-11873, at 411.

³⁴⁴¹ 50 CFR 402.14(a). The Services recently issued a final rule revising the regulations governing the ESA Section 7 consultation process. 84 FR 44976 (Aug. 27, 2019). The effective date of the new regulations was subsequently delayed to October 28, 2019. 84 FR 50333 (Sep. 25, 2019). As discussed in the text above, the agencies believe that their conclusion would be the same under both the current and prior regulations.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

occur *but for* the proposed action and it is *reasonably certain to occur*.³⁴⁴² The revised definition made explicit a “but for” test and the concept of “reasonably certain to occur” for all effects.³⁴⁴³ However, in the preamble to the final rule, the Services emphasized that the “but for” test and “reasonably certain to occur” are not new or heightened standards.³⁴⁴⁴ In this context, “‘but for’ causation means that the consequence in question would not occur if the proposed action did not go forward In other words, if the agency fails to take the proposed action and the activity would still occur, there is no ‘but for’ causation. In that event, the activity would not be considered an effect of the action under consultation.”³⁴⁴⁵

The revised ESA regulations also provide a framework for determining whether consequences are caused by a proposed action and are therefore “effects” that may trigger consultation. The regulations provide in part:

To be considered an effect of a proposed action, a consequence must be caused by the proposed action (*i.e.*, the consequence would not occur but for the proposed action and is reasonably certain to occur). A conclusion of reasonably certain to occur must be based on clear and substantial information, using the best scientific and commercial data available. Considerations for determining that a consequence to the species or critical habitat is not caused by the proposed action include, but are not limited to:

- (1) The consequence is so remote in time from the action under consultation that it is not reasonably certain to occur; or
- (2) The consequence is so geographically remote from the immediate area involved in the action that it is not reasonably certain to occur; or
- (3) The consequence is only reached through a lengthy causal chain that involves so many steps as to make the consequence not reasonably certain to occur.³⁴⁴⁶

³⁴⁴² 50 CFR 402.02 (emphasis added), as amended by 84 FR 44976, 45016 (Aug. 27, 2019).

³⁴⁴³ The Services’ prior regulations defined “effects of the action” in relevant part as “the direct and indirect effects of an action on the species or critical habitat, together with the effects of other activities that are interrelated or interdependent with that action, that will be added to the environmental baseline.” 50 CFR 402.02 (as in effect prior to Oct. 28, 2019). Indirect effects were defined as “those that are caused by the proposed action and are later in time, but still are reasonably certain to occur.” *Id.*

³⁴⁴⁴ 84 FR at 44977 (“As discussed in the proposed rule, the Services have applied the ‘but for’ test to determine causation for decades. That is, we have looked at the consequences of an action and used the causation standard of ‘but for’ plus an element of foreseeability (*i.e.*, reasonably certain to occur) to determine whether the consequence was caused by the action under consultation.”).

³⁴⁴⁵ *Id.* We note that as the Services do not consider this to be a change in their longstanding application of the ESA, this interpretation applies equally under the prior regulations (which were effective through October 28, 2019, and the current regulations).

³⁴⁴⁶ 50 CFR 402.17(b).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The regulations go on to make clear that the action agency must factor these considerations into its assessments of potential effects.³⁴⁴⁷

DOI, the agency charged with co-administering the ESA, previously evaluated whether CO₂ emissions associated with a specific proposed Federal action triggered ESA Section 7(a)(2) consultation. The agencies have reviewed the long history of actions and guidance provided by DOI. To that point, the agencies incorporate by reference Appendix G of the MY 2012-2016 CAFE standards EIS.³⁴⁴⁸ That analysis relied on the significant legal and technical analysis undertaken by FWS and DOI. Specifically, NHTSA looked at the history of the Polar Bear Special Rule and several guidance memoranda provided by FWS and the U.S. Geological Survey. Ultimately, DOI concluded that a causal link could not be made between CO₂ emissions associated with a proposed Federal action and specific effects on listed species; therefore, no Section 7(a)(2) consultation would be required.

Subsequent to the publication of that Appendix, a court vacated the Polar Bear Special Rule on NEPA grounds, though it upheld the ESA analysis as having a rational basis.³⁴⁴⁹ FWS then issued a revised Final Special Rule for the Polar Bear.³⁴⁵⁰ In that final rule, FWS provided that for ESA Section 7, the determination of whether consultation is triggered is narrow and focused on the discrete effect of the proposed agency action. FWS wrote, “[T]he consultation requirement is triggered only if there is a causal connection between the proposed action and a discernible effect to the species or critical habitat that is reasonably certain to occur. One must be able to ‘connect the dots’ between an effect of a proposed action and an impact to the species and there must be a reasonable certainty that the effect will occur.”³⁴⁵¹ The statement in the revised Final Special Rule is consistent with the prior guidance published by FWS and remains valid today.³⁴⁵² Likewise, the current regulations identify remoteness in time, geography, and the causal chain as factors to be considered in assessing whether a consequence is “reasonably certain to occur.” If the consequence is not reasonably certain to occur, it is not an “effect of a proposed action” and does not trigger the consultation requirement.

The agencies’ actions establishing CAFE and CO₂ standards for passenger cars and light trucks do not directly affect listed species or critical habitat. The regulations promulgated by the agencies are used to calculate average standards for manufacturers based on the vehicles they produce for sale in the United States. Any potential effects of this action on listed species or

³⁴⁵² See DOI Solicitor’s Opinion No. M-37017, “Guidance on the Applicability of the Endangered Species Act Consultation Requirements to Proposed Actions Involving the Emissions of Greenhouse Gases” (Oct. 3, 2008).

designated critical habitat would be a result of changes to CO₂ or air pollutant emissions that are caused by the individual choices of manufacturers in producing these vehicles and consumers in purchasing and operating those vehicles. The agencies are not requiring, authorizing, funding, or carrying out the operation of motor vehicles (i.e., the proximate cause of downstream emissions), the production or refining of fuel (i.e., a proximate cause of upstream emissions),³⁴⁵³ the use of any land that is critical habitat for any purpose, or the taking of any listed species or other activity that may affect any listed species. Ultimately, the relevant decisions that result in emissions are taken by third parties, and any on-the-ground activities to implement and carry out those decisions are undertaken by such third parties. These decisions are influenced by a complex series of market factors that, though influenced by the agencies' actions, could result in the same series of decisions by consumers that commenters attribute to the agencies' actions (such as increased VMT and therefore increased emissions). This complex and lengthy chain of causality, which is highly dependent on market factors and therefore uncertain, leads the agencies to conclude that the resulting impacts of their actions to listed species or critical habitat do not satisfy the "but for" test or are "reasonably certain to occur."

With regard to climate change, EPA and NHTSA are not able to make a causal link for purposes of Section 7(a)(2) that would "connect the dots" between their actions, vehicle emissions from motor vehicles affected by their actions, climate change, and particular impacts to listed species or critical habitats. The agencies' actions are to set standards that are effectively footprint curves, which are used as part of a complex calculation based on the vehicles produced by manufacturers for sale in the United States to determine a corporate average standard for each manufacturer. This approach, dictated by the Federal statute, gives manufactures significant discretion to design, produce, and sell motor vehicles to meet consumer demand. Because manufacturers could choose to produce more vehicles with larger footprints (and therefore less stringent standards), fleet-average CO₂ emissions could increase year-over-year independently of where the agencies set standards. Or the opposite may be true, and a shift in consumer preferences could lead to increased production of vehicles with smaller footprints (and therefore more stringent standards), resulting in overall declines in CO₂ emissions in the future compared to what the agencies are forecasting. Consumers not only choose which vehicles to purchase across a range of available fuel economies, they also choose how much to operate those vehicles (and therefore the quantity of fuel used and CO₂ emitted) independently of any action undertaken by the agencies.^{3454, 3455}

³⁴⁵³ The agencies note that upstream emissions sources, such as oil extraction sites and fuel refineries, remain subject to the ESA. As future non-federal activities become reasonably certain, Section 7 and/or other sections of the ESA may provide protection for listed species and designated critical habitats. For example, new oil exploration or extraction activity may result in permitting or construction activities that would trigger consultation or other activities for the protection of listed species or designated critical habitat, as impacts may be more direct and more certain to occur.

³⁴⁵⁴ While VMT is affected by the cost of driving associated with fuel economy (i.e., the rebound effect), it is also affected by several market factors, such as economic conditions, that are far beyond the agencies' control.

³⁴⁵⁵ The fact that overall CO₂ emissions are influenced so heavily by consumer preferences and behavior further supports the agencies' conclusion that impacts are not "reasonably certain to occur."

Even with so many third parties in the causal chain making independent choices influenced by independent factors, the mechanics of climate change itself further breaks the chain of causality in this case. Climate change is a global phenomenon, impacted by greenhouse gas emissions that could occur anywhere throughout the world. As these gases accumulate in the atmosphere, radiative forcing increases, resulting in various potential impacts to the global climate system (e.g., warming temperatures, droughts, and changes in ocean pH). These changes could directly or indirectly impact listed species and/or designated critical habitat over time. Although this is a simplified explanation of a complex phenomenon subject to a significant degree of scientific study, it illustrates that the potential climate change-related consequences of this rulemaking on listed species and designated critical habitat are not “reasonably certain to occur” under any of the three tests in the ESA regulations and listed above. Not only are the consequences geographically and temporally remote from the emissions that result from regulated vehicles, the chain of causality is simply too lengthy and complex. Because impacts to listed species and designated critical habitat result from climate shifts that, in and of themselves, result from the accumulation over time of greenhouse gas emissions from anywhere in the world, there is simply no way to “connect the dots” between the emissions from a regulated vehicle and those impacts. While the potential impacts of climate change have been well-documented, there is no degree of certainty that this action (as distinct from any other source of CO₂ emissions) would be the cause of any particular impact to listed species or critical habitats. Because greenhouse gas emissions continue to occur from other sectors within the U.S. and from other sources globally, there is simply no scientific way to apportion any impact to a listed species or designated critical habitat to the agencies’ actions.³⁴⁵⁶

One comment to the NPRM documented the potential impacts of climate change on Federally protected species and included a five-page table of species listed during 2006 to 2015 for which the commenters claim climate change was a listing factor.³⁴⁵⁷ This conflates the requirements of ESA Section 4 (governing ESA listing) and ESA Section 7 (addressing the obligations of Federal agencies). Section 4 requires FWS or NMFS to assess all threats to species regardless of the origin of those threats. 16 U.S.C. § 1533(a)(1). In contrast, the focus of Section 7(a)(2) is narrower and requires agencies to assess only effects on species that are attributable to the specific agency action. 16 U.S.C. § 1536(a)(2). Thus, that climate change was considered as a factor in a determination to list a species does not speak to the separate inquiry of whether the specific agency action is impacting a listed species. Here, the agencies believe this comment inappropriately attributes the entire issue of climate change, including all CO₂ emissions no matter which sector generated them, to NHTSA and EPA’s actions. As explained above, however, the link between a specific agency action that may result in some contribution to climate change and the effects on a specific listed species is too remote to trigger Section

³⁴⁵⁶ See 50 CFR 402.17(b) (“A conclusion of reasonably certain to occur must be based on clear and substantial information, using the best scientific and commercial data available.”)

³⁴⁵⁷ Center for Biological Diversity, Sierra Club, and Public Citizen, Inc., Docket No. NHTSA-2018-0067-12378, at 25-30.

7(a)(2) consultation. This is true even to the extent the commenter only intends to suggest that the agencies' actions would exacerbate the impacts of climate change.^{3458, 3459}

As noted above, for consultation to be required, there must exist a sufficient nexus between the agency activity and the impact on listed species that the ESA intends to avoid. The Services have defined that nexus as “but for” causation. However, there is no “but for” causation associated with this final rule as the impacts of climate change will occur regardless of this action. In fact, even if the agencies were to set CAFE and CO₂ standards at levels that would eliminate all CO₂ emissions from motor vehicles made available for sale in the United States, the impacts of climate change are still projected to occur due to emissions from other sectors in the United States and other sources globally. Changes to tailpipe greenhouse gas emissions or associated upstream emissions related to this rulemaking and the alternatives considered would be very small compared to global CO₂ emissions, which would continue. The agencies also note that because third parties (as described above) undertake most of the decisions that result in emissions, increased greenhouse gas emissions could occur regardless of the agencies' actions in this final rule. This further demonstrates the lack of “but for” causality in this case.

Criteria air pollutant emissions from passenger cars and light trucks differ from greenhouse gas emissions in many ways. Most significantly, because passenger cars and light trucks are subject to gram-per-mile emissions standards for criteria pollutants, more fuel-efficient (and, correspondingly, less CO₂-intensive) vehicles are not, from the standpoint of air quality, “cleaner” vehicles. Therefore, to the extent that CAFE and CO₂ standards lead to changes in overall quantities of vehicular emissions that impact air quality, these are dominated by induced changes in highway travel. Changes in overall fuel consumption do lead to changes in emissions from “upstream” processes involved in supplying fuel to vehicles. Depending on how total vehicular emissions and total upstream emissions change in response to less stringent standards, overall emissions could increase or decrease.

While small in magnitude, net impacts could also vary considerably among different geographic areas depending on the locations of upstream emission sources and where changes in highway travel occur. This is important because of another significant difference between criteria air pollutant emissions and greenhouse gas emissions: criteria air pollutant emissions are localized whereas CO₂ emissions contribute to global climate change no matter where they occur. As reported in Section 4.1.1 of the FEIS, concentrations of many air pollutants emitted

³⁴⁵⁸ Such a broad interpretation of the ESA would ensnare every Federal action that resulted in even an additional ounce of additional carbon dioxide emissions into the Section 7(a)(2) consultation process. *See, e.g.*, 78 FR 11766, 11785 (Feb. 20, 2013) (“Without the requirement of a causal connection between the action under consultation and effects to species, literally every agency action that contributes CO₂ emissions to the atmosphere would arguably result in consultation with respect to every listed species that may be affected by climate change.”).

³⁴⁵⁹ The agencies also disagree that, for purposes of compliance with the ESA, this action would exacerbate climate change impacts on listed species or critical habitat. This final rule establishes CAFE and CO₂ standards that increase in stringency on a year-by-year basis. While these standards are less stringent than the standards published in the 2012 rulemaking, the ESA does not serve as a one-way ratchet when agencies use their inherent authority to reconsider decisions that have not yet taken effect.

from motor vehicles are elevated in ambient air within approximately 1,000 to 2,000 feet of major roadways. With meteorological conditions that tend to inhibit the dispersion of emissions, concentrations of traffic-generated air pollutants can be elevated for as much as about 8,500 feet downwind of roads.^{3460, 3461} But this means that impacts of criteria pollutant emissions are highly dependent on where they occur, to a degree much more significant than greenhouse gas emissions. Although the agencies anticipate increased fuel use as a result of this final rule (compared to the standards described in the 2012 final rule), the NHTSA and EPA have no way to know with reasonable certainty where additional fuel extraction and refining will occur. The agencies also cannot calculate with reasonable certainty where changes in highway travel will occur, as those impacts may not be uniform across the country. Therefore, even with the best scientific and commercial data available, the agencies cannot draw conclusions on impacts on listed species or designated critical habitat.

In other words, CAFE and CO₂ standards impact fuel consumption and CO₂ emissions in ways that are direct and unambiguous, and impact air quality in ways that are indirect and ambiguous. Criteria pollutant emissions changes are even less “reasonably certain to occur” than CO₂ emissions changes, and they are certainly more difficult to quantify reliably. All of the conclusions above regarding climate change not only apply to criteria pollutant emissions as well, but do so even more clearly. For example, the causal chain between the agencies’ actions and any impacts to listed species or designated critical habitat is even further attenuated by the fact that independent third parties must choose not only how much to operate their motor vehicles, but where to operate those motor vehicles as well. And the agencies cannot meaningfully distinguish between criteria pollutant impacts caused by other sources and the regulated vehicles, let alone whether the emissions from the regulated vehicles changed meaningfully as a result of this rule. Current modeling tools available are not designed to trace fluctuations in ambient concentration levels of criteria and toxic air pollutants to potential impacts on particular endangered species. The agencies therefore cannot conclude that impacts are “reasonably certain to occur.”³⁴⁶²

Impacts on criteria pollutant emissions as a result of this rule, especially in light of other emissions sources besides the regulated vehicles, are small.³⁴⁶³ Nevertheless, though the agencies anticipate that increases in emissions of some air pollutants may occur, motor vehicles remain subject to emissions standards established by EPA. Furthermore, States are still subject to the National Ambient Air Quality Standards established by EPA under the Clean Air Act.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

These rules, which protect the nation's public health and the environment, would operate to limit the impact of any criteria air pollutant emissions changes that could occur from this action.

Finally, the agencies also note the uncertainty that remains related to changes in total air pollutant and CO₂ emissions as a result of flexibilities associated with the CAFE and CO₂ programs. Both programs allow manufacturers to trade and apply credits they have earned from over-compliance in lieu of meeting their standards for a particular model year, and manufacturers may have planned to rely on credits to comply with the standards for the model years regulated by this action. This could offset any changes in emissions that would result from the agencies' final decision. Furthermore, NHTSA's CAFE program allows manufacturers to pay civil penalties to cover any shortfall in compliance, further offsetting potential improvements in fuel economy (and, therefore, changes in air pollutant and CO₂ emissions) that might have occurred under the augural standards. The existence of these flexibilities further supports the agencies' conclusion that they can establish neither "but for" causation nor a reasonable certainty that impacts will occur on listed species or designated critical habitat.

The agencies have considered this analysis and conclude that any consequence to specific listed species or designated critical habitats from climate change or other air pollutant emissions is too remote and uncertain to be attributable to the agencies' actions here. These consequences are not "effects" for purposes of consultation under Section 7(a)(2). NHTSA and EPA therefore conclude that this final rule has no effect on listed species or their critical habitats.

b) The Agencies Lack Sufficient Discretion or Control to Bring These Actions under the Consultation Requirement of the ESA

[Text Forthcoming]

7. Floodplain Management (Executive Order 11988 and DOT Order 5650.2)

These Orders require Federal agencies to avoid the long- and short-term adverse impacts associated with the occupancy and modification of floodplains, and to restore and preserve the natural and beneficial values served by floodplains. Executive Order 11988 also directs agencies to minimize the impact of floods on human safety, health, and welfare, and to restore and preserve the natural and beneficial values served by floodplains through evaluating the potential effects of any actions the agency may take in a floodplain and ensuring that its program planning and budget requests reflect consideration of flood hazards and floodplain management. DOT Order 5650.2 sets forth DOT policies and procedures for implementing Executive Order 11988. The DOT Order requires that the agency determine if a proposed action is within the limits of a base floodplain, meaning it is encroaching on the floodplain, and whether this encroachment is significant. If significant, the agency is required to conduct further analysis of the proposed action and any practicable alternatives. If a practicable alternative avoids floodplain encroachment, then the agency is required to implement it.

In this rulemaking, the agencies are not occupying, modifying and/or encroaching on floodplains. The agencies, therefore, conclude that the Orders are not applicable to this action.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NHTSA has, however, conducted a review of the alternatives on potentially affected resources, including floodplains, in its FEIS.

8. Preservation of the Nation's Wetlands (Executive Order 11990 and DOT Order 5660.1a)

These Orders require Federal agencies to avoid, to the extent possible, undertaking or providing assistance for new construction located in wetlands unless the agency head finds that there is no practicable alternative to such construction and that the proposed action includes all practicable measures to minimize harm to wetlands that may result from such use. Executive Order 11990 also directs agencies to take action to minimize the destruction, loss, or degradation of wetlands in "conducting Federal activities and programs affecting land use, including but not limited to water and related land resources planning, regulating, and licensing activities." DOT Order 5660.1a sets forth DOT policy for interpreting Executive Order 11990 and requires that transportation projects "located in or having an impact on wetlands" should be conducted to assure protection of the Nation's wetlands. If a project does have a significant impact on wetlands, an EIS must be prepared.

In the NPRM, the agencies noted that they are not undertaking or providing assistance for new construction located in wetlands. The agencies, therefore, concluded that these Orders do not apply to this rulemaking. One commenter disagreed with this conclusion, noting the potential land use impacts of the rule and the agencies' obligation to consider all factors relevant to the proposal's effect on the survival and quality of wetlands.³⁴⁶⁴ The agencies do not believe that it is feasible to establish the requisite causal chain between the impacts of this action and impacts on wetlands, nor would such impacts be reasonably foreseeable as a direct or indirect result of this rulemaking. We therefore continue to conclude that these Orders do not apply to this rulemaking. Regardless, NHTSA addresses the potential effects of the alternatives on resources, including wetlands, in its FEIS.

9. Migratory Bird Treaty Act (MBTA), Bald and Golden Eagle Protection Act (BGEPA), Executive Order 13186

The MBTA (16 U.S.C. 703–712) provides for the protection of certain migratory birds by making it illegal for anyone to "pursue, hunt, take, capture, kill, attempt to take, capture, or kill, possess, offer for sale, sell, offer to barter, barter, offer to purchase, purchase, deliver for shipment, ship, export, import, cause to be shipped, exported, or imported, deliver for transportation, transport or cause to be transported, carry or cause to be carried, or receive for shipment, transportation, carriage, or export" any migratory bird covered under the statute.³⁴⁶⁵

³⁴⁶⁴ Joint Submission from the States of California *et al.* and the Cities of Oakland *et al.*, Docket No. NHTSA-2018-0067-11735, at 46-47.

³⁴⁶⁵ 16 U.S.C. 703(a).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The BGEPA (16 U.S.C. 668-668d) makes it illegal to “take, possess, sell, purchase, barter, offer to sell, purchase or barter, transport, export or import” any bald or golden eagles.³⁴⁶⁶ Executive Order 13186, “Responsibilities of Federal Agencies to Protect Migratory Birds,” helps to further the purposes of the MBTA by requiring a Federal agency to develop a Memorandum of Understanding (MOU) with the Fish and Wildlife Service when it is taking an action that has (or is likely to have) a measurable negative impact on migratory bird populations.

The agencies conclude that the MBTA, BGEPA, and Executive Order 13186 do not apply to this action because there is no disturbance, take, measurable negative impact, or other covered activity involving migratory birds or bald or golden eagles involved in this rulemaking.

10. Department of Transportation Act (Section 4(f))

Section 4(f) of the Department of Transportation Act of 1966 (49 U.S.C. 303), as amended, is designed to preserve publicly owned park and recreation lands, waterfowl and wildlife refuges, and historic sites. Specifically, Section 4(f) provides that DOT agencies cannot approve a transportation program or project that requires the use of any publicly owned land from a public park, recreation area, or wildlife or waterfowl refuge of national, State, or local significance, or any land from a historic site of national, State, or local significance, unless a determination is made that:

(1) There is no feasible and prudent alternative to the use of land, and

(2) The program or project includes all possible planning to minimize harm to the property resulting from the use.

These requirements may be satisfied if the transportation use of a Section 4(f) property results in a de minimis impact on the area.

NHTSA concludes that Section 4(f) is not applicable to this action because this rulemaking is not an approval of a transportation program or project that requires the use of any publicly owned land.

11. Executive Order 12898: “Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations”

Executive Order 12898 (59 FR 7629 (Feb. 16, 1994)) establishes Federal executive policy on environmental justice. It directs Federal agencies, to the greatest extent practicable and permitted by law, to make environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations in the

³⁴⁶⁶ 16 U.S.C. 668(a).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

United States. DOT Order 5610.2(a)³⁴⁶⁷ sets forth the Department of Transportation's policy to consider environmental justice principles in all its programs, policies, and activities.

Environmental justice is a principle asserting that all people deserve fair treatment and meaningful involvement with respect to environmental laws, regulations, and policies. EPA seeks to provide the same degree of protection from environmental health hazards for all people. DOT shares this goal and is informed about the potential environmental impacts of its rulemakings through the NEPA process. One comment on the NPRM claimed that the agencies "failed to recognize the benefits of the existing standards" for disadvantaged communities. Specifically, the commenter claimed that the agencies did not provide an underlying analysis of environmental justice issues and thereby failed to meet the requirements of EO 12898.³⁴⁶⁸ However, the agencies addressed their obligations under EO 12898 in the preamble to the NPRM and in Section 7.5 of the DEIS. The agencies received a number of comments regarding the analysis it presented. NHTSA responds to those comments in Section 10.7 of the FEIS, and the agencies have revised their environmental justice analysis based on the information contained in those comments. The revised analysis is presented here and in the FEIS.

There is evidence that proximity to oil refineries could be correlated with incidences of cancer and leukemia.^{3469, 3470, 3471} Proximity to high-traffic roadways could result in adverse

cardiovascular and respiratory impacts, among other possible impacts.^{3472, 3473, 3474, 3475, 3476, 3477,}

³⁴⁷⁸ Climate change affects overall global temperatures, which could, in turn, affect the number and severity of outbreaks of vector-borne illnesses.^{3479, 3480} In the context of this rulemaking, the environmental justice concern is the extent to which minority and low-income populations could be more exposed or vulnerable to such environmental and health impacts.

Numerous studies have found that some environmental hazards are more prevalent in areas where racial/ethnic minorities and people with low socioeconomic status represent a higher proportion of the population compared with the general population. In addition, compared to non-Hispanic whites, some subpopulations defined by race and ethnicity have been shown to have a greater incidence of some health conditions during certain life stages. For example, in 2014, about 13 percent of Black, non-Hispanic and 24 percent of Puerto Rican children were estimated to have asthma, compared with 8 percent of white, non-Hispanic children.³⁴⁸¹ The agencies have therefore considered areas nationwide that could contain minority and low-income communities who would most likely be exposed to the environmental and health impacts of oil production, distribution, and consumption or the potential impacts of climate change. These include areas where oil production and refining occur, areas near roadways, coastal flood-prone areas, and urban areas that are subject to the heat island effect.³⁴⁸²

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

The following discussion addresses environmental justice implications related to air quality and to climate change and carbon emissions in the context of this final rulemaking. Emissions of air pollutants may be affected by this rulemaking due to changes in fuel use and VMT, which are described above. To the degree to which minority and low-income populations may be present in proximity to the locations described in this section, they may be exposed disproportionately to these emissions changes. In addition, the following analysis also discusses other potential reasons why minority and low-income populations may be susceptible to the health impacts of air pollutants. NHTSA also discusses environmental justice in Chapter 7.5 of its FEIS.

a) Proximity to Oil Production and Refining

As stated above, numerous studies have found that some environmental hazards are more prevalent in areas where minority and low-income populations represent a higher proportion of the population compared with the general population. For example, one study found that survey respondents who were black and, to a lesser degree, had lower income levels, were significantly more likely to live within 1 mile of an industrial facility listed in the EPA's 1987 Toxic Release Inventory (TRI) national database.³⁴⁸³

A meta-analysis of 49 environmental equity studies concluded that evidence of race-based environmental inequities is statistically significant (although the average magnitude of these inequities is small), while evidence supporting the existence of income-based environmental inequities is substantially weaker.³⁴⁸⁴ Considering poverty-based class effects, that meta-analysis found an inverse relationship between environmental risk and poverty, concluding that environmental risks are less likely to be located in areas of extreme poverty.³⁴⁸⁵ However, individual studies may reach contradictory conclusions in relation to race- and income-based inequities across a range of environmental risks. Therefore, the meta-analysis also sought to examine the reasons why conclusions vary across studies of environmental inequity. Possible explanations for why studies reach contrary conclusions include variability in the source of potential environmental risk that the study considers (e.g., the type of facility or the associated level of pollution or risk); variability in the methodology applied to aggregate demographic data and to define the comparison population; and the degree to which statistical models control for other variables that may explain the distribution of potential environmental risk.

To test whether there are disparate impacts from hazardous industrial facilities on racial/ethnic minorities, the disadvantaged, the working class, and manufacturing workers, one

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

study tested the relationship between hazard scores of Philadelphia-area facilities in EPA's Risk-Screening Environmental Indicators (RSEI) database and the demographics of populations near those facilities using multivariate regression.³⁴⁸⁶ This study concluded that racial/ethnic minorities, the most socioeconomically disadvantaged, and those employed in manufacturing suffer a disparate impact from the highest-hazard facilities (primarily manufacturing plants).

Other commissioned reports and case studies provide additional evidence of the presence of low-income and minority populations near industrial facilities and of racial or socioeconomic disparities in exposure to environmental risk, although these sources were not published in peer-reviewed scientific journals.^{3487, 3488, 3489, 3490}

Few studies address disproportionate exposure to environmental risk associated with oil refineries specifically. One study found that the populations surrounding oil refineries are more often minorities, concluding that "56 percent of people living within three miles of [oil] refineries in the United States are minorities – almost double the national average."³⁴⁹¹ Another examined whether findings of environmental inequity varied between coke production plants and oil refineries, both of which are significant sources of air pollution.³⁴⁹² This study concluded that census tracts near coke plants had a disproportionate share of poor and nonwhite residents, and that existing inequities were primarily economic in nature. However, the findings for oil refineries did not strongly support an environmental inequity hypothesis. A more recent study of environmental justice in the oil refinery industry found evidence of environmental injustice as a

Environmental Health Perspectives 112 (1):61–66 (2004). Available at: <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1241798/>. (Accessed: May 31, 2018).

result of unemployment levels in areas around refineries and, to a slightly lesser extent, as a result of income inequality.³⁴⁹³ This study did not test for race-based environmental inequities.

Overall, the body of scientific literature points to disproportionate representation of minority and low-income populations in proximity to a range of industrial, manufacturing, and hazardous waste facilities that are stationary sources of air pollution; although results of individual studies may vary. While the scientific literature specific to oil refineries is limited, disproportionate exposure of minority and low-income populations to air pollution from oil refineries is suggested by other broader studies of racial and socioeconomic disparities in proximity to industrial facilities generally.

The potential increase in fuel production and consumption projected as a result of this rulemaking (compared to the No Action Alternative) could lead to an increase in upstream emissions of criteria and toxic air pollutants due to increased extraction, refining, and transportation of fuel. As described in Section VII.A.4.c.3.b.i, total upstream emissions of criteria and toxic air pollutants in 2035 are projected to increase under all action alternatives compared to the No Action Alternative, with the exception that total upstream emissions of SO₂ are projected to decrease under all action alternatives under the CAFE program (but not under the CO₂ program). As noted, a correlation between proximity to oil refineries and the prevalence of minority and low-income populations is suggested in the scientific literature. To the extent that minority and low-income populations live closer to oil refining facilities, these populations may be more likely to be adversely affected by these emissions. However, the magnitude of the change in emissions relative to the baseline is minor and would not be characterized as high and adverse.

b) Proximity to High-Traffic Roadways

Studies have more consistently demonstrated a disproportionate prevalence of minority and low-income populations living near mobile sources of pollutants. In certain locations in the United States, for example, there is consistent evidence that populations or schools near roadways typically include a greater percentage of minority or low-income residents.^{3494, 3495, 3496,}

^{3497, 3498, 3499, 3500} In California, studies demonstrate that minorities and low-income populations are disproportionately likely to live near a major roadway or in areas of high traffic density compared to the general population.^{3501, 3502} A study of traffic, air pollution, and socio-economic status inside and outside the Minneapolis-St. Paul metropolitan area similarly found that populations on the lower end of the socioeconomic spectrum and minorities are disproportionately exposed to traffic and air pollution and at higher risk for adverse health outcomes.³⁵⁰³ Near-road exposure to vehicle emissions can cause or exacerbate health conditions such as asthma.^{3504, 3505, 3506, 3507} One study demonstrated that students at schools in Michigan closer to major highways had a higher risk of respiratory and neurological disease and were more likely to fail to meet state educational standards, after controlling for other variables.³⁵⁰⁸ In general, studies such as these demonstrate trends in specific locations in the United States that may be indicative of broader national trends.

Fewer studies have been conducted at the national level, yet those that do exist also demonstrate a correlation between minority and low-income status and proximity to

roadways.^{3509, 3510} For example, one study found that greater traffic volumes and densities at the national level are associated with larger shares of minority and low-income populations living in the vicinity.³⁵¹¹ Another study found that schools with minority and underprivileged³⁵¹² children were disproportionately located within 250 meters of a major roadway.³⁵¹³

As detailed in Section 10.3.8 of the PRIA and Section X.E.11.a.2 of the FRIA, NHTSA and EPA analyzed two national databases that allowed evaluation of whether homes and schools were located near a major road and whether disparities in exposure may be occurring in these environments. The American Housing Survey (AHS) includes descriptive statistics of over 70,000 housing units across the nation. The study survey is conducted every two years by the U.S. Census Bureau. The second database the agencies analyzed was the U.S. Department of Education's Common Core of Data, which includes enrollment and location information for schools across the U.S.

In analyzing the 2009 AHS, the focus was on whether or not a housing unit was located within 300 feet of a "4-or-more lane highway, railroad, or airport."³⁵¹⁴ Whether there were differences between households in such locations compared with those in locations farther from these transportation facilities was analyzed.³⁵¹⁵ Other variables, such as land use category, region of country, and housing type, were included. Homes with a nonwhite householder were found to be 22 to 34 percent more likely to be located within 300 feet of these large transportation facilities than homes with white householders. Homes with a Hispanic householder were 17 to 33 percent more likely to be located within 300 feet of these large transportation facilities than homes with non-Hispanic householders. Households near large transportation facilities were, on average, lower in income and educational attainment, more

³⁵¹⁴ This variable primarily represents roadway proximity. According to the Central Intelligence Agency's World Factbook, in 2010, the United States had 6,506,204 km of roadways, 224,792 km of railways, and 15,079 airports. Highways thus represent the overwhelming majority of transportation facilities described by this factor in the AHS.

³⁵¹⁵ Bailey, C. (2011) Demographic and Social Patterns in Housing Units Near Large Highways and other Transportation Sources. Memorandum to docket.

likely to be a rental property, and more likely to be located in an urban area compared with households more distant from transportation facilities.

In examining schools near major roadways, the Common Core of Data (CCD) from the U.S. Department of Education, which includes information on all public elementary and secondary schools and school districts nationwide, was examined.³⁵¹⁶ To determine school proximities to major roadways, a geographic information system (GIS) to map each school and roadways based on the U.S. Census's TIGER roadway file was used.³⁵¹⁷ Minority students were found to be overrepresented at schools within 200 meters of the largest roadways, and schools within 200 meters of the largest roadways also had higher than expected numbers of students eligible for free or reduced-price lunches. For example, Black students represent 22 percent of students at schools located within 200 meters of a primary road, whereas Black students represent 17 percent of students in all U.S. schools. Hispanic students represent 30 percent of students at schools located within 200 meters of a primary road, whereas Hispanic students represent 22 percent of students in all U.S. schools.

Overall, there is substantial evidence that the population who lives or attends school near major roadways are more likely to be minority or low income. As described in Section VII.A.4.c.3.b.i, total downstream (tailpipe) emissions of criteria and toxic air pollutants for cars and light trucks in 2035 are projected to remain relatively unchanged or decrease under all action alternatives compared to the No Action Alternative, with the following exceptions: total downstream emissions of SO₂ would increase under all action alternatives under both the CAFE and CO₂ programs; total downstream emissions of acrolein would increase under Alternatives 5, 6, and 7 under the CAFE program (but not under the CO₂ program); and total downstream emissions of acetaldehyde and butadiene would increase under Alternatives 6 and 7 under the CAFE program (but not under the CO₂ program). To the extent minority and low-income populations disproportionately live or attend schools near major roadways, these populations may be more likely to be affected by these emissions. However, because some pollutant emissions are expected to decrease and others are expected to increase, health impacts are mixed. Overall, as the magnitude of the emissions changes is anticipated to be minor compared to total tailpipe emissions for these vehicles, the impacts to minority or low-income populations are not considered high and adverse.

The agencies used the standards that were discussed in the 2012 rulemaking as the baseline for this rulemaking. Therefore, the agencies project increases in certain air pollutants for purposes of this analysis. However, as discussed above, one impact of the standards finalized in this rulemaking is to reduce the up-front cost of new and used vehicles. Low income populations may benefit most from the reduction in cost of acquiring newer vehicles, which generally are more fuel efficient and have lower air pollutant emissions than older vehicles. This cost reduction may have the effect of encouraging the quicker adoption of cleaner vehicles in

³⁵¹⁶ <http://nces.ed.gov/ccd/>.

³⁵¹⁷ Pedde, M.; Bailey, C. Identification of Schools within 200 Meters of U.S. Primary and Secondary Roads. Memorandum to the docket (2011).

low income communities, which could result in air quality and health benefits for those who live or attend school in proximity to the roadways where they are operated. To the degree to which minority populations may also live in proximity to these roadways, they would also experience benefits, thereby mitigating the disparity in racial, ethnic, and economically based exposures.

c) *Other Vulnerabilities to Climate Change and Health Impacts of Air Pollutants*

Some areas most vulnerable to climate change tend to have a higher concentration of minority and low-income populations, potentially putting these communities at higher risk from climate variability and climate-related extreme weather events.³⁵¹⁸ For example, urban areas tend to have pronounced social inequities that could result in disproportionately larger minority and low-income populations than those in the surrounding nonurban areas.³⁵¹⁹ Urban areas are also subject to the most substantial temperature increases from climate change because of the urban heat island effect.^{3520, 3521, 3522} Taken together, these tendencies demonstrate a potential for disproportionate impacts on minority and low-income populations in urban areas. Low-income populations in coastal urban areas, which are vulnerable to increases in flooding as a result of projected sea-level rise, larger storm surges, and human settlement in floodplains, could also be disproportionately affected by climate change because they are less likely to have the means to evacuate quickly in the event of a natural disaster and, therefore, are at greater risk of injury and loss of life.^{3523, 3524}

Independent of their proximity to pollution sources or climate change, locations of potentially high impact, minority and low-income populations could be more vulnerable to the health impacts of pollutants and climate change. Reports from the U.S. Department of Health and Human Services have stated that minority and low-income populations tend to have less access to health care services, and the services received are more likely to suffer with respect to

³⁵²⁴ GCRP (2014).

quality.^{3525, 3526, 3527} Other studies show that low socioeconomic position can modify the health effects of air pollution, with higher effects observed in groups with lower socioeconomic position.^{3528, 3529} Possible explanations for this observation include that low socioeconomic position groups may be differentially exposed to air pollution or may be differentially vulnerable to effects of exposure.³⁵³⁰

In terms of climate change, increases in heat-related morbidity and mortality because of higher overall and extreme temperatures are likely to affect minority and low-income populations disproportionately, partially because of limited access to air conditioning and high energy costs.^{3531, 3532, 3533, 3534} Native American tribes and Alaskan Native villages are also more susceptible to the impacts of climate change, as these groups often disproportionately rely on natural resources for livelihoods, medicines, and cultural and spiritual purposes.³⁵³⁵ Moreover, coastal tribal communities may have to relocate because of sea-level rise, erosion, and permafrost thaw.³⁵³⁶ NHTSA's FEIS provides additional discussion of health and societal

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

impacts of climate change on indigenous communities in Section 8.6.5.2, *Sectoral Impacts of Climate Change*, under *Human Health and Human Security*.

Together, this information indicates that the same set of potential environmental effects (e.g., air pollutants, heat increases, and sea-level rise) may disproportionately affect minority and low-income populations because of socioeconomic circumstances or histories of discrimination and inequity.

As described in Chapter 5 of NHTSA's FEIS, the action alternatives are projected to increase CO₂ emissions from passenger cars and light trucks by 4 to 10 percent by 2100 compared to the No Action Alternative. Impacts of climate change could disproportionately affect minority and low-income populations in urban areas that are subject to the most substantial temperature increases from climate change. These impacts are largely because of the urban heat island effect. Additionally, minority and low-income populations that live in flood-prone coastal areas could be disproportionately affected. However, the contribution of the action alternatives to climate change impacts would be very minor rather than high and adverse. Compared to the annual U.S. CO₂ emissions of 7,193 MMTCO₂e from all sources by the end of the century projected by the GCAM Reference scenario, the action alternatives are projected to increase annual U.S. CO₂ emissions by 0.4 to 1.2 percent in 2100. Compared to annual global CO₂ emissions, the action alternatives would represent an even smaller percentage increase and ultimately, by 2100, are projected to result in percentage increases in global mean surface temperature, atmospheric CO₂ concentrations, and sea level, and decreases in ocean pH, ranging from 0.09 percent to less than 0.01 percent. Any impacts of this rulemaking on low-income and minority communities would be attenuated by a lengthy causal chain; but if one could attempt to draw those links, the changes to climate values would be very small and incremental compared to the expected changes associated with the emissions trajectories in the GCAM Reference scenario.

As reported in Section VII.A.4.c.3.c above, adverse health impacts over the lifetimes of vehicles through MY 2029 are projected to increase nationwide under each of the action alternatives (except Alternative 6 and Alternative 7 under the CAFE program, which show decreases) compared to the No Action Alternative. Increases in these pollutant emissions, however, would be primarily the result of increases in upstream emissions (emissions near refineries, power plants, and extraction sites), while downstream emissions (tailpipe emissions near roadways) are anticipated to decrease or increase by smaller amounts. The health impacts reported in that section occur over a long period of time, would be incremental in magnitude, and would not be characterized as high. Those impacts would also be borne nationwide, so impacts to minority and low-income populations would be smaller.

d) Conclusion

Based on the foregoing, the agencies have determined that this rulemaking (and alternatives considered) would not result in disproportionately high and adverse human health or environmental effects on minority or low-income populations. This rulemaking would set standards nationwide, and although minority and low-income populations may experience some

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

disproportionate effects, in particular locations, the overall impacts on human health and the environment would not be “high and adverse” under EO 12898.

Furthermore, the agencies note that there are no mitigation measures or alternatives available as part of this action that could fulfill the respective statutory missions of the agencies and that would address the considerations discussed in Section VIII (e.g., economic practicability) or avoid or reduce any disproportionate effects in particular locations experienced by minority and low-income populations. The impacts described in this analysis would result from air pollutant and CO₂ emissions that may occur from the levels of stringency selected by the agencies. However, for the reasons described in Section VIII, the agencies cannot select a higher level of stringency. While the agencies have considered the potential impacts described in this analysis, there is a substantial need, based on the overall public interest, to address the costs associated with the standards discussed in the 2012 rulemaking. More stringent alternatives would have severe adverse social and economic costs, as described in Section VIII, and necessitate the level of standards finalized in this rulemaking.

12. Executive Order 13045: “Protection of Children from Environmental Health Risks and Safety Risks”

This action is subject to EO 13045 (62 FR 19885, April 23, 1997) because it is an economically significant regulatory action as defined by EO 12866, and the agencies have reason to believe that the environmental health or safety risks related to this action may have a disproportionate effect on children. Specifically, children are more vulnerable to adverse health effects related to mobile source emissions, as well as to the potential long-term impacts of climate change. Pursuant to EO 13045, NHTSA and EPA must prepare an evaluation of the environmental health or safety effects of the planned regulation on children and an explanation of why the planned regulation is preferable to other potentially effective and reasonably feasible alternatives considered by the agencies. Further, this analysis may be included as part of any other required analysis.

This preamble and NHTSA’s Final EIS discuss air quality, climate change, and their related environmental and health effects, noting where these would disproportionately affect children. The EPA Administrator has also discussed the impact of climate-related health effects on children in the Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act (74 FR 66496, December 15, 2009). In addition, this preamble explains why the agencies’ final standards are preferable to other alternatives considered. Together, this preamble and NHTSA’s Final EIS satisfy the agencies’ responsibilities under EO 13045.

F. Regulatory Flexibility Act

Pursuant to the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*, as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA) of 1996), whenever an agency is required to publish a notice of proposed rulemaking or final rule, it must prepare and make available for public comment a regulatory flexibility analysis that describes the effect of the rule on small entities (*i.e.*, small businesses, small organizations, and small governmental

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

jurisdictions). No regulatory flexibility analysis is required if the head of an agency certifies the rule will not have a significant economic impact on a substantial number of small entities. SBREFA amended the Regulatory Flexibility Act to require Federal agencies to provide a statement of the factual basis for certifying that a rule will not have a significant economic impact on a substantial number of small entities.

Two comments argued that the agencies should prepare a regulatory flexibility analysis and convene a small business review panel to assess the impacts in accordance with the Regulatory Flexibility Act, 5 U.S.C. 601 *et seq.*, as amended by SBREFA.³⁵³⁷ The agencies considered these comments and the impacts of this rule under the Regulatory Flexibility Act and certify that this rule will not have a significant economic impact on a substantial number of small entities. The following is the agencies' statement providing the factual basis for this certification pursuant to 5 U.S.C. 605(b).

Small businesses are defined based on the North American Industry Classification System (NAICS) code.³⁵³⁸ One of the criteria for determining size is the number of employees in the firm. For establishments primarily engaged in manufacturing or assembling automobiles, as well as light duty trucks, the firm must have less than 1,500 employees to be classified as a small business. This rule would affect motor vehicle manufacturers. As shown in [Table X-1](#), the agencies have identified 15 small manufacturers of passenger cars, light trucks, and SUVs of electric, hybrid, and internal combustion engines.³⁵³⁹ The agencies acknowledge that some newer manufacturers may not be listed. However, those new manufacturers tend to have transportation products that are not part of the light-duty vehicle fleet and have yet to start production of light-duty vehicles. Moreover, NHTSA does not believe that there are a "substantial number" of these newer companies.³⁵⁴⁰

Table X-1 - Small Domestic Vehicle Manufacturers

Manufacturers	Founded	Employees ³⁵⁴¹	Estimated Annual Production ³⁵⁴²	Sale Price per Unit
Karma Automotive	2014	625	900	\$130,000

³⁵³⁷ See National Coalition for Advanced Transportation (NCAT) Comment, Docket No. NHTSA-2018-0067-11969, at 64-65; Workhorse Group, Inc. Comment, Docket No. NHTSA-2018-0067-12215, at 1-2.

³⁵³⁸ Classified in NAICS under Subsector 336—Transportation Equipment Manufacturing for Automobile Manufacturing (336111), Light Truck (336112), and Heavy Duty Truck Manufacturing (336120). <https://www.sba.gov/document/support-table-size-standards>.

³⁵³⁹ Two comments pointed out that Workhorse Group Inc. was not listed as a small domestic vehicle manufacturer in Table XII-1 of the proposal. See National Coalition for Advanced Transportation (NCAT) Comment, Docket No. NHTSA-2018-0067-11969, at 64-65; Workhorse Group, Inc. Comment, Docket No. NHTSA-2018-0067-12215, at 1-2. Workhorse Group has been added to the table here, but neither its addition nor the existence of a small number of other new small manufacturers does not alter the conclusion that this rule will not have a significant economic impact on a substantial number of small entities.

NHTSA believes that the rulemaking would not have a significant economic impact on the small vehicle manufacturers because under 49 CFR part 525, passenger car manufacturers making less than 10,000 vehicles per year can petition NHTSA to have alternative standards set for those manufacturers. These manufacturers do not currently meet the 27.5 mpg standard and must already petition the agency for relief. If the standard is raised, it has no meaningful impact on these manufacturers—they still must go through the same process and petition for relief. Given there already is a mechanism for relieving burden on small businesses, which is the purpose of the Regulatory Flexibility Act, a regulatory flexibility analysis was not prepared.

Two comments argued that small manufacturers of electric vehicles would face a significant economic impact because their ability to earn credits would be “substantially diminished.”³⁵⁴³ The method for earning credits applies equally across manufacturers and does not place small entities at a significant competitive disadvantage. In any event, even if the rule had a “significant economic impact” on these small EV manufacturers, the amount of these companies is not “a substantial number.”³⁵⁴⁴ For these reasons, their existence does not alter the agencies’ analysis of the applicability of the Regulatory Flexibility Act. EPA believes this rulemaking would not have a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act, as amended by the Small Business Regulatory Enforcement Fairness Act. EPA is exempting from the CO₂ standards any manufacturer, domestic or foreign, meeting SBA’s size definitions of small business as described in 13 CFR 121.201. EPA adopted the same type of exemption for small businesses in the 2017 and later rulemaking. EPA estimates that small entities comprise less than 0.1 percent of total annual vehicle sales and exempting them will have a negligible impact on the CO₂ emissions reductions

³⁵⁴³ National Coalition for Advanced Transportation (NCAT) Comment, Docket No. NHTSA-2018-0067-11969, at 65; Workhorse Group, Inc. Comment, Docket No. NHTSA-2018-0067-12215, at 2.

³⁵⁴⁴ 5 U.S.C. 605.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

from the standards. Because EPA is exempting small businesses from the CO₂ standards, the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities. Therefore, EPA has not conducted a Regulatory Flexibility Analysis or a SBREFA SBAR Panel for the rule.

EPA regulations allow small businesses voluntarily to waive their small business exemption and optionally to certify to the CO₂ standards. This option allows small entity manufacturers to earn CO₂ credits under the CO₂ program, if their actual fleetwide CO₂ performance is better than their fleetwide CO₂ target standard. However, the exemption waiver is optional for small entities and thus the agency believes that manufacturers opt into the CO₂ program if it is economically advantageous for them to do so, for example in order to generate and sell CO₂ credits. Therefore, EPA believes this voluntary option does not affect EPA's determination that the standards will impose no significant adverse impact on small entities.

G. Executive Order 13132 (Federalism)

Executive Order 13132 requires Federal agencies to develop an accountable process to ensure “meaningful and timely input by State and local officials in the development of regulatory policies that have federalism implications.” The Order defines the term “[p]olicies that have federalism implications” to include regulations that have “substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government.” Under the Order, agencies may not issue a regulation that has federalism implications, that imposes substantial direct compliance costs, unless the Federal government provides the funds necessary to pay the direct compliance costs incurred by State and local governments, or the agencies consult with State and local officials early in the process of developing the proposed regulation. The agencies complied with the Order's requirements.

NHTSA also addressed the federalism implications of its proposal in The Safer Affordable Fuel-Efficient Vehicles Rule Part One: One National Program final rulemaking.³⁵⁴⁵

H. Executive Order 12988 (Civil Justice Reform)

Pursuant to Executive Order 12988, “Civil Justice Reform,”³⁵⁴⁶ NHTSA has considered whether this rulemaking would have any retroactive effect. This proposed rule does not have any retroactive effect.

³⁵⁴⁵ 84 FR 51310 (Sep. 27, 2019).

³⁵⁴⁶ 61 FR 4729 (Feb. 7, 1996).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

I. Executive Order 13175 (Consultation and Coordination With Indian Tribal Governments)

This final rule does not have tribal implications, as specified in Executive Order 13175 (65 FR 67249, November 9, 2000). This rule will be implemented at the Federal level and impose compliance costs only on vehicle manufacturers. Thus, Executive Order 13175 does not apply to this rule. Some comments complained that the agencies have not consulted or coordinated with Native American communities and Indian Tribes in promulgating this rule.³⁵⁴⁷ Executive Order 13175 requires consultation with Tribal officials when agencies are developing policies that have “substantial direct effects” on Tribes and Tribal interests.³⁵⁴⁸ Even accepting the comments’ description of the effects of the rule, they have identified only indirect effects of the standards on Tribal interests.³⁵⁴⁹

J. Unfunded Mandates Reform Act

Section 202 of the Unfunded Mandates Reform Act of 1995 (UMRA) requires Federal agencies to prepare a written assessment of the costs, benefits, and other effects of a proposed or final rule that includes a Federal mandate likely to result in the expenditure by State, local, or Tribal governments, in the aggregate, or by the private sector, of more than \$100 million in any one year (adjusted for inflation with base year of 1995). Adjusting this amount by the implicit gross domestic product price deflator for 2016 results in \$148 million ($111.416/75.324 = 1.48$).³⁵⁵⁰ Before promulgating a rule for which a written statement is needed, section 205 of UMRA generally requires NHTSA and EPA to identify and consider a reasonable number of regulatory alternatives and adopt the least costly, most cost-effective, or least burdensome alternative that achieves the objective of the rule. The provisions of section 205 do not apply when they are inconsistent with applicable law. Moreover, section 205 allows NHTSA and EPA to adopt an alternative other than the least costly, most cost-effective, or least burdensome alternative if the agency publishes with the rule an explanation of why that alternative was not adopted.

This rule will not result in the expenditure by State, local, or Tribal governments, in the aggregate, of more than \$148 million annually, but it will result in the expenditure of that magnitude by vehicle manufacturers and/or their suppliers. In developing this rule, NHTSA and EPA considered a variety of alternative average fuel economy standards lower and higher than

³⁵⁴⁷ See, e.g., CARB Comment, Docket No. NHTSA-2018-0067-11873, at 412; National Tribal Air Association Comment, Docket No. NHTSA-2018-0067-11948, at 4; Keweenaw Bay Indian Community Comment, Docket No. EPA-HQ-OAR-2018-0283-3325, at 1-2; Fond du Lac Band of Lake Superior Chippewa Comment, Docket No. EPA-HQ-OAR-2018-0283-4030, at 3; Sac and Fox Nation, Docket No. EPA-HQ-OAR-2018-0283-4159, at 4-5; The Leech Lake Band of Ojibwe Comment, Docket No. EPA-HQ-OAR-2018-0283-5931, at 4-5.

³⁵⁴⁸ 65 FR 67249, 67249 (Nov. 6, 2000).

³⁵⁴⁹ See, e.g., National Tribal Air Association Comment, Docket No. NHTSA-2018-0067-11948, at 4.

³⁵⁵⁰ Bureau of Economic Analysis, National Income and Product Accounts (NIPA), Table 1.1.9 Implicit Price Deflators for Gross Domestic Product. https://bea.gov/iTable/index_nipa.cfm.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

those previously proposed. The fuel economy standards for MYs 2021-2026 are the least costly, most cost-effective, and least burdensome alternative that achieve the objectives of the rule.

K. Regulation Identifier Number

The Department of Transportation assigns a regulation identifier number (RIN) to each regulatory action listed in the Unified Agenda of Federal Regulations. The Regulatory Information Service Center publishes the Unified Agenda in April and October of each year. The RIN contained in the heading at the beginning of this document may be used to find this action in the Unified Agenda.

L. National Technology Transfer and Advancement Act

Section 12(d) of the National Technology Transfer and Advancement Act (NTTAA) requires NHTSA and EPA to evaluate and use existing voluntary consensus standards in its regulatory activities unless doing so would be inconsistent with applicable law (*e.g.*, the statutory provisions regarding NHTSA's vehicle safety authority, or EPA's testing authority) or otherwise impractical.³⁵⁵¹

Voluntary consensus standards are technical standards developed or adopted by voluntary consensus standards bodies. Technical standards are defined by the NTTAA as "performance-based or design-specific technical specification and related management systems practices." They pertain to "products and processes, such as size, strength, or technical performance of a product, process or material."

Examples of organizations generally regarded as voluntary consensus standards bodies include the American Society for Testing and Materials (ASTM), the Society of Automotive Engineers (SAE), and the American National Standards Institute (ANSI). If the agencies do not use available and potentially applicable voluntary consensus standards, they are required by the Act to provide Congress, through OMB, an explanation of the reasons for not using such standards.

For CO₂ emissions, EPA will collect data over the same tests that are used for the MY 2012-2016 CO₂ standards and for the CAFE program. This unified data collection will minimize the amount of testing done by manufacturers because manufacturers are already required to run these tests. For A/C credits, EPA will use a consensus methodology developed by the Society of Automotive Engineers (SAE) and also a new A/C test. EPA knows of no consensus standard available for the A/C test.

There are currently no voluntary consensus standards that NHTSA administers relevant to today's CAFE standards.

³⁵⁵¹ 15 U.S.C. 272.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

M. Department of Energy Review

In accordance with 49 U.S.C. 32902(j)(2), NHTSA submitted this rule to the Department of Energy for review.

N. Paperwork Reduction Act

The Paperwork Reduction Act (PRA) of 1995, Public Law 104-13,³⁵⁵² gives OMB authority to regulate matters regarding the collection, management, storage, and dissemination of certain information by and for the Federal government. It seeks to reduce the total amount of paperwork handled by the government and the public. NHTSA strives to reduce the public's information collection burden hours each fiscal year by streamlining external and internal processes.

To this end, NHTSA will continue to collect information to ensure compliance with its CAFE program. NHTSA will reinstate its previously-approved collection of information for Corporate Average Fuel Economy (CAFE) reports specified in 49 CFR part 537 (OMB control number 2127-0019), add the additional burden for reporting changes adopted in the October 15, 2012 final rule that recently came into effect (*see* 77 FR 62623), and account for the change in burden in this rule as well as for other CAFE reporting provisions required by Congress and NHTSA. NHTSA is also changing the name of this collection to represent more accurately the breadth of all CAFE regulatory reporting. Although NHTSA is adding additional burden hours to its CAFE report requirement in 49 CFR 537, the agency believes there will be a reduction in the overall paperwork burden due to the standardization of data and the streamlined process.

In compliance with the PRA, the information collection request (ICR) abstracted below was forwarded to OMB for review and comment. The ICR describes the nature of the information collection and its expected burden.

Title: Corporate Average Fuel Economy.

Type of Request: Reinstatement and amendment of a previously approved collection.

OMB Control Number: 2127-0019.

Form Numbers: NHTSA Form 1474 (CAFE Projections Reporting Template) and NHTSA Form 1475 (CAFE Credit Template).

Requested Expiration Date of Approval: Three years from date of approval.

Summary of the collection of information: As part of this rulemaking, NHTSA is reinstating and modifying its previously-approved collection for CAFE-related collections of information. NHTSA and EPA have coordinated their compliance and reporting requirements in

³⁵⁵² Codified at 44 U.S.C. 3501 *et seq.*

an effort not to impose duplicative burdens on regulated entities. This information collection contains three different components: burden related to NHTSA's CAFE reporting requirements; burden related to CAFE compliance, but not via reporting requirements; and information gathered by NHTSA to help inform CAFE analyses. All templates referenced in this section will be available in the rulemaking docket and the NHTSA public information center³⁵⁵³.

1. CAFE Compliance Reports

NHTSA is reinstating³⁵⁵⁴ its collection related to the reporting requirements in 49 U.S.C. 32907, "Reports and tests of manufacturers." In that section, manufacturers are statutorily required to submit CAFE compliance reports to the Secretary of Transportation.³⁵⁵⁵ The reports must state if a manufacturer will comply with its applicable fuel economy standard(s), describe what actions the manufacturer intends to take to comply with the standard(s), and include other information as required by NHTSA. Manufacturers are required to submit two CAFE compliance reports—a pre-model year report (PMY) and a mid-model year (MMY) report—each year. In the event a manufacturer needs to correct previously-submitted information, a manufacturer may need to file additional reports.³⁵⁵⁶

To implement this statute, NHTSA issued 49 CFR part 537, "Automotive Fuel Economy Reports," which adds additional definition to the terms of section 32907. The first report, the PMY report must be submitted to NHTSA before December 31 of the calendar year prior to the corresponding model year and contain manufacturers' projected information for that upcoming model year. The second report, the MMY report must be submitted by July 31 of the given model year and contain updated information from manufacturers based on actual and projected information known midway through the model year. Finally, the last report, a supplementary report, is required to be submitted anytime a manufacturer needs to correct information previously submitted to NHTSA.

Compliance reports must include information on passenger and non-passenger automobiles (trucks) describing the projected and actual fuel economy standards, fuel economy performance values, production sales volumes and information on vehicle design features (*e.g.*, engine displacement and transmission class) and other vehicle attribute characteristics (*e.g.*, track width, wheel base, and other light truck off-road features). Manufacturers submit confidential and non-confidential versions of these reports to NHTSA. Confidential reports differ by

³⁵⁵³ https://one.nhtsa.gov/cafe_pic/CAFE_PIC_Home.htm

³⁵⁵⁴ This collection expired on April 30, 2016.

³⁵⁵⁵ 49 U.S.C. 32907 (delegated to the NHTSA Administrator at 49 CFR 1.95). Because of this delegation, for purposes of discussion, statutory references to the Secretary of Transportation in this section will be discussed in terms of NHTSA or the NHTSA Administrator.

³⁵⁵⁶ Specifically, a manufacturer shall submit a report containing the information during the 30 days before the beginning of each model year, and during the 30 days beginning the 180th day of the model year. When a manufacturer decides that actions reported are not sufficient to ensure compliance with that standard, the manufacturer shall report additional actions it intends to take to comply with the standard and include a statement about whether those actions are sufficient to ensure compliance.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

including estimated or actual production sales information, which is withheld from public disclosure to protect each manufacturer's competitive sales strategies. NHTSA uses the reports as the basis for vehicle auditing and testing, which helps manufacturers correct reporting errors prior to the end of the model year and facilitate acceptance of their final CAFE report by the Environmental Protection Agency (EPA). The reports also help the agency, as well as the manufacturers who prepare them, anticipate potential compliance issues as early as possible, and help manufacturers plan their compliance strategies.

Further, NHTSA is modifying this collection to account for additional information manufacturers are required to include in their reports. In the CAFE standards previously promulgated for MY 2017 and beyond,³⁵⁵⁷ NHTSA allowed for manufacturers to gain additional fuel economy benefits by installing certain technologies on their vehicles beginning with MY 2017.³⁵⁵⁸ These technologies include air-conditioning systems with increased efficiency, off-cycle technologies whose benefits are not adequately captured on the Federal Test Procedure and/or the Highway Fuel Economy Test,³⁵⁵⁹ and hybrid electric technologies installed on full-size pickup trucks. Prior to MY 2017, manufacturers were unable to earn a fuel economy benefit for these technologies, so NHTSA's reporting requirements did not include an opportunity to report them. Now, manufacturers must provide information on these technologies in their CAFE reports. NHTSA requires manufacturers to provide detailed information on the model types using these technologies to gain fuel economy benefits. These details are necessary to facilitate NHTSA's technical analyses and to ensure the agency can perform random enforcement audits when necessary.

In addition to a list of all fuel consumption improvement technologies utilized in their fleet, 49 CFR 537 requires manufacturers to report the make, model type, compliance category, and production volume of each vehicle equipped with each technology and the associated fuel consumption improvement value (FCIV). NHTSA is adding the reporting and enforcement burden hours and cost for these new incentives to this collection. Manufacturers can also petition the EPA and NHTSA, in accordance with 40 CFR 86.1868-12 or 40 CFR 86.1869-12, to gain additional credits based upon the improved performance of any of the new incentivized technologies allowed starting in model year 2017. EPA approves these petitions in collaboration with NHTSA and any adjustments are taken into account for both programs. As a part the agencies' coordination, NHTSA provides EPA with an evaluation of each new technology to ensure its direct impact on fuel economy and an assessment on the suitability of each technology for use in increasing a manufacturer's fuel economy performance. Furthermore, at times, NHTSA may independently request additional information from a manufacturer to support its evaluations. This information along with any research conclusions shared with EPA and NHTSA in the petitions is required to be submitted in manufacturer's CAFE reports.

³⁵⁵⁷ 77 FR 62623 (Oct. 15, 2012).

³⁵⁵⁸ These technologies were not included in the burden for part 537 at the time as the additional reporting requirements would not take effect until years later.

³⁵⁵⁹ *E.g.*, engine idle stop-start systems, active transmission warmup systems, etc.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

NHTSA is also changing the burden hours for its CAFE reporting requirements in 49 CFR part 537 by adjusting the total amount of time spent collecting the required reporting information through the use of a standardized reporting template to streamline the collection process. The standardized template will be used by manufacturers to collect all the required CAFE information under 49 CFR 537.7(b) and (c) and provides a format which ensures accuracy, completeness, and better alignment with the final data provided to EPA.

2. Other CAFE Compliance Collections

NHTSA is adopting a new standardized template for manufacturers buying CAFE credits and for manufacturers submitting credit transactions in accordance with 49 CFR part 536. In 49 CFR part 536.5(d), NHTSA is required to assess compliance with fuel economy standards each year, utilizing the certified and reported CAFE data provided by the EPA for enforcement of the CAFE program pursuant to 49 U.S.C. 32904(e). Credit values are calculated based on the CAFE data from the EPA. If a manufacturer's vehicles in a particular compliance category performs better than its required fuel economy standard, NHTSA adds credits to the manufacturer's account for that compliance category. If a manufacturer's vehicles in a particular compliance category perform worse than the required fuel economy standard, NHTSA will add a credit deficit to the manufacturer's account and will provide written notification to the manufacturer concerning its failure to comply. The manufacturer will be required to confirm the shortfall and must either: submit a plan indicating how it will allocate existing credits or earn, transfer, and/or acquire credits or pay the equivalent civil penalty. The manufacturer must submit a plan or payment within 60 days of receiving notification from NHTSA.

Manufacturers should use the credit transaction template any time a credit transaction request is sent to NHTSA. For example, manufacturers that purchase credits and want to apply them to their credit accounts will use the credit transaction template. The template NHTSA is adopting is a simple spreadsheet that credit entities fill out. When completed, credit entities will have an organized list of credit transactions and will be able to click a button on the spreadsheet to generate a joint transaction letter for trading parties to sign and submit to NHTSA, along with the spreadsheet. Entities trading credits are also required to provide to NHTSA all the confidential information associated with the monetary and non-monetary price of credit trades. NHTSA believes these changes will significantly reduce the burden on manufacturers in managing their CAFE credit accounts and provide better oversight of the CAFE credit program for NHTSA.

Finally, NHTSA is accounting for the additional burden due to existing CAFE program elements. In 49 CFR part 525, small volume manufacturers submit petitions to NHTSA for exemption from an applicable average fuel economy standard and to request to comply with a less stringent alternative average fuel economy standard. In 49 CFR part 534, manufacturers are required to submit information to NHTSA when establishing a corporate controlled relationship with another manufacturer. A controlled relationship exists between manufacturers that control, are controlled by, or are under common control with, one or more other manufacturers. Accordingly, manufacturers that have entered into written contracts transferring rights and responsibilities to other manufacturers in controlled relationships for CAFE purposes are required to provide reports to NHTSA. There are additional reporting requirements for

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

manufacturers submitting carry back plans and when manufacturers split apart from controlled relationships and must designate how credits are to be allocated between the parties.³⁵⁶⁰ Manufacturers with credit deficits at the end of the model year, can carry back future earned credits up to three model years in advance of the deficit to resolve a current shortfall. The carryback plan proving the existence of a manufacturer's future earned credits must be submitted and approved by NHTSA, pursuant to 49 U.S.C. 32903(b).

3. Analysis Fleet Composition

As discussed in Section VI.B, in setting CAFE standards, NHTSA creates an analysis fleet from which to model potential future economy improvements. To compose this fleet, the agency uses a mixture of compliance data and information from other sources to replicate more closely the fleet from a recent model year. While refining the analysis fleet, NHTSA occasionally asks manufacturers for information that is similar to information submitted as part of EPA's final model year report (e.g., final model year vehicle volumes). Periodically, NHTSA may ask manufacturers for more detailed information than what is required for compliance (e.g., what engines are shared across vehicle models). Often, NHTSA requests this information from manufacturers after manufacturers have submitted their final model year reports to EPA, but before EPA processes and releases final model year reports.

Information like this, which is used to verify and supplement the data used to create the analysis fleet, is tremendously valuable to generating an accurate analysis fleet, and setting maximum feasible standards. The more accurate the analysis fleet is, the more accurate the modeling of what technologies could be applied will be. Therefore, NHTSA is accounting for the burden on manufacturers to provide the agency with this additional information. In almost all instances, manufacturers already have the information NHTSA seeks, but it might need to be reformatted or recompiled. Because of this, NHTSA believes the burden to provide this information will often be minimal.

Affected Public: Respondents are manufacturers of engines and vehicles within the North American Industry Classification System (NAICS) and use the coding structure as defined by NAICS including codes 33611, 336111, 336112, 33631, 33631, 33632, 336320, 33635, and 336350 for motor vehicle and parts manufacturing.

Respondent's obligation to respond: Regulated entities are required to respond to inquiries covered by this collection. 49 U.S.C. 32907. 49 CFR part 525, 534, 536, and 537.

Frequency of response: Variable, based on compliance obligation. Please see PRA supporting documentation in the docket for more detailed information.

Average burden time per response: Variable, based on compliance obligation. Please see PRA supporting documentation in the docket for more detailed information.

³⁵⁶⁰ See 49 CFR part 536.

Number of respondents: 23.

4. Estimated Total Annual Burden Hours and Costs:

Table X-2 - Estimated Burden for Reporting Requirements

Applies to:	Manufacturer		Government	
	Hours	Cost	Hours	Cost
Prior Collection	3,189.00	\$24,573.50	975.00	\$31,529.00
Current Collection	4,018.73	\$198,885.02	3,038.00	\$141,246.78
Difference	829.73	\$174,311.52	2,063.00	\$109,717.78

O. Privacy Act

In accordance with 5 U.S.C. 553(c), the agencies solicited comments from the public to inform the rulemaking process better. These comments are posted, without edit, to www.regulations.gov, as described in DOT's system of records notice, DOT/ALL-14 FDMS, accessible through www.transportation.gov/privacy. In order to facilitate comment tracking and response, the agencies encouraged commenters to provide their names, or the names of their organizations; however, submission of names is completely optional.

Regulatory Text

For the reasons discussed in the preamble, the National Highway Traffic Safety Administration amends 49 CFR chapter V as follows:

List of Subjects

49 CFR Part 523, 531, and 533

Fuel economy.

49 CFR Part 536 and 537

Fuel economy, Reporting and recordkeeping requirements.

PART 523 – VEHICLE CLASSIFICATION

1. The authority citation for part 523 continues to read as follows:

Authority: 49 U.S.C 32901; delegation of authority at 49 CFR 1.95.

2. Amend § 523.2 by revising the definitions of “Curb weight” and “Full-size pickup truck” to read as follows:

§ 523.2 Definitions.

* * * * *

Curb weight has the meaning given in 40 CFR 86.1803-01.

* * * * *

Full-size pickup truck means a light truck or medium duty passenger vehicle that meets the specifications in 40 CFR 86.1803-01.

* * * * *

PART 531 – PASSENGER AUTOMOBILE AVERAGE FUEL ECONOMY STANDARDS

3. The authority citation for part 531 is revised to read as follows:

Authority: 49 U.S.C. 32902; delegation of authority at 49 CFR 1.95.

4. Amend § 531.5 by revising the introductory text of paragraph (c), Table III to paragraph (c), and paragraph (d), removing paragraph (e), and redesignating paragraph (f) as paragraph (e) to read as follows:

§ 531.5 Fuel economy standards.

* * * * *

(c) For model years 2012-2026, a manufacturer's passenger automobile fleet shall comply with the fleet average fuel economy level calculated for that model year according to Figure 2 and the appropriate values in Table III.

* * *

TABLE III – PARAMETERS FOR THE PASSENGER AUTOMOBILE FUEL ECONOMY TARGETS, MYS
2012-2026

Model year	Parameters

(d) In addition to the requirements of paragraphs (b) and (c) of this section, each manufacturer shall also meet the minimum fleet standard for domestically manufactured passenger automobiles expressed in Table IV:

[text forthcoming]

* * * * *

5. Amend § 531.6 by revising paragraphs (a) and (b) to read as follows:

§ 531.6 Measurement and calculation procedures.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(a) The fleet average fuel economy performance of all passenger automobiles that are manufactured by a manufacturer in a model year shall be determined in accordance with procedures established by the Administrator of the Environmental Protection Agency under 49 U.S.C. 32904 and set forth in 40 CFR part 600. For model years 2017 to 2026, a manufacturer is eligible to increase the fuel economy performance of passenger cars in accordance with procedures established by the EPA set forth in 40 CFR 600, Subpart F, including any adjustments to fuel economy the EPA allows, such as for fuel consumption improvements related to air conditioning efficiency and off-cycle technologies.

(1) A manufacturer that seeks to increase its fleet average fuel economy performance through the use of technologies that improve the efficiency of air conditioning systems must follow the requirements in 40 CFR 86.1868-12. Fuel consumption improvement values resulting from the use of those air conditioning systems must be determined in accordance with 40 CFR 600.510-12(c)(3)(i).

(2) A manufacturer that seeks to increase its fleet average fuel economy performance through the use of off-cycle technologies must follow the requirements in 40 CFR 86.1869-12. A manufacturer is eligible to gain fuel consumption improvements for predefined off-cycle technologies in accordance with 40 CFR 86.1869-12(b) or for technologies tested using the EPA's 5-cycle methodology in accordance with 40 CFR 86.1869-12(c). The fuel consumption improvement is determined in accordance with 40 CFR 600.510-12(c)(3)(ii).

(b) A manufacturer is eligible to increase its fuel economy performance through use of an off-cycle technology requiring an application request made to the EPA in accordance with 40 CFR 86.1869-12(d). The request must be approved by the EPA in consultation with NHTSA. To expedite NHTSA's consultation with the EPA, a manufacturer shall concurrently submit its

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

application to NHTSA if the manufacturer is seeking off-cycle fuel economy improvement values under the CAFE program for those technologies. For off-cycle technologies that are covered under 40 CFR 86.1869-12(d), NHTSA will consult with the EPA regarding NHTSA's evaluation of the specific off-cycle technology to ensure its impact on fuel economy and the suitability of using the off-cycle technology to adjust the fuel economy performance. NHTSA will provide its views on the suitability of the technology for that purpose to the EPA. NHTSA's evaluation and review will consider:

- (1) Whether the technology has a direct impact upon improving fuel economy performance;
- (2) Whether the technology is related to crash-avoidance technologies, safety critical systems or systems affecting safety-critical functions, or technologies designed for the purpose of reducing the frequency of vehicle crashes;
- (3) Information from any assessments conducted by the EPA related to the application, the technology and/or related technologies; and
- (4) Any other relevant factors.

PART 533 – LIGHT TRUCK FUEL ECONOMY STANDARDS

6. The authority citation for part 533 is revised to read as follows:

Authority: 49 U.S.C. 32902; delegation of authority at 49 CFR 1.95.

7. Amend § 533.5 by revising Table VII to paragraph (a) to read as follows and removing paragraph (k).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

§ 533.5 Requirements.

(a) * * * * *

2026	42.82	27.64	0.000469	0.00410				

8. Amend § 533.6 by revising paragraphs (b) and (c) to read as follows:

§ 533.6 Measurement and calculation procedures.

* * * * *

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(b) The fleet average fuel economy performance of all light trucks that are manufactured by a manufacturer in a model year shall be determined in accordance with procedures established by the Administrator of the Environmental Protection Agency under 49 U.S.C. 32904 and set forth in 40 CFR part 600. For model years 2017 to 2026, a manufacturer is eligible to increase the fuel economy performance of light trucks in accordance with procedures established by the EPA set forth in 40 CFR part 600, Subpart F, including any adjustments to fuel economy the EPA allows, such as for fuel consumption improvements related to air conditioning efficiency, off-cycle technologies, and hybridization and other performance-based technologies for full-size pickup trucks that meet the requirements specified in 40 CFR 86.1803.

(1) A manufacturer that seeks to increase its fleet average fuel economy performance through the use of technologies that improve the efficiency of air conditioning systems must follow the requirements in 40 CFR 86.1868-12. Fuel consumption improvement values resulting from the use of those air conditioning systems must be determined in accordance with 40 CFR 600.510-12(c)(3)(i).

(2) A manufacturer that seeks to increase its fleet average fuel economy performance through the use of off-cycle technologies must follow the requirements in 40 CFR 86.1869-12. A manufacturer is eligible to gain fuel consumption improvements for predefined off-cycle technologies in accordance with 40 CFR 86.1869-12(b) or for technologies tested using the EPA's 5-cycle methodology in accordance with 40 CFR 86.1869-12(c). The fuel consumption improvement is determined in accordance with 40 CFR 600.510-12(c)(3)(ii).

(3) The eligibility of a manufacturer to increase its fuel economy using hybridized and other performance-based technologies for full-size pickup trucks must follow 40 CFR 86.1870-

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

12 and the fuel consumption improvement of these full-size pickup truck technologies must be determined in accordance with 40 CFR 600.510-12(c)(3)(iii).

(c) A manufacturer is eligible to increase its fuel economy performance through use of an off-cycle technology requiring an application request made to the EPA in accordance with 40 CFR 86.1869-12(d). The request must be approved by the EPA in consultation with NHTSA. To expedite NHTSA's consultation with the EPA, a manufacturer shall concurrently submit its application to NHTSA if the manufacturer is seeking off-cycle fuel economy improvement values under the CAFE program for those technologies. For off-cycle technologies that are covered under 40 CFR 86.1869-12(d), NHTSA will consult with the EPA regarding NHTSA's evaluation of the specific off-cycle technology to ensure its impact on fuel economy and the suitability of using the off-cycle technology to adjust the fuel economy performance. NHTSA will provide its views on the suitability of the technology for that purpose to the EPA. NHTSA's evaluation and review will consider:

- (1) Whether the technology has a direct impact upon improving fuel economy performance;
- (2) Whether the technology is related to crash-avoidance technologies, safety critical systems or systems affecting safety-critical functions, or technologies designed for the purpose of reducing the frequency of vehicle crashes;
- (3) Information from any assessments conducted by the EPA related to the application, the technology and/or related technologies; and
- (4) Any other relevant factors.

**PART 535 – MEDIUM- AND HEAVY-DUTY VEHICLE FUEL EFFICIENCY
PROGRAM**

9. The authority citation for part 535 continues to read as follows:

Authority: 49 U.S.C. 32902 and 30101; delegation of authority at 49 CFR 1.95.

10. Amend § 535.6 by revising paragraphs (a)(4)(ii) and (d)(5)(ii) to read as follows:

§ 535.6 Measurement and calculation procedures.

* * * * *

(a) * * *

(4) * * *

(ii) Calculate the equivalent fuel consumption test group results as follows for spark-ignition vehicles and alternative fuel spark-ignition vehicles. CO₂ emissions test group result (grams per mile)/((8,887 grams per gallon of gasoline fuel) × (10⁻²)) = Fuel consumption test group result (gallons per 100 mile).

* * * * *

(d) * * *

(5) * * *

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(ii) Calculate equivalent fuel consumption FCL values for spark-ignition engines and alternative fuel spark-ignition engines. CO_2 FCL value (grams per hp-hr)/((8,887 grams per gallon of gasoline fuel) $\times (10^{-2})$) = Fuel consumption FCL value (gallons per 100 hp-hr).

* * * * *

12. Amend § 535.7 by revising the equations in paragraphs (b)(1), (c)(1), (d)(1), (e)(2), and (f)(2)(iii)(E) to read as follows:

§ 535.7 Averaging, banking, and trading (ABT) credit program.

* * * * *

(b) * * *

(1) * * *

Total MY Fleet FCC (gallons) = (Std – Act) \times (Volume) \times (UL) $\times (10^{-2})$

Where:

Std = Fleet average fuel consumption standard (gal/100 mile).

Act = Fleet average actual fuel consumption value (gal/100 mile).

Volume = the total U.S.-directed production of vehicles in the regulatory subcategory.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

UL = the useful life for the regulatory subcategory. The useful life value for heavy-pickup trucks and vans manufactured for model years 2013 through 2020 is equal to the 120,000 miles. The useful life for model years 2021 and later is equal to 150,000 miles.

* * * * *

(c) * * *

(1) * * *

Vehicle Family FCC (gallons) = (Std – FEL) × (Payload) × (Volume) × (UL) × (10⁻³)

Where:

Std = the standard for the respective vehicle family regulatory subcategory (gal/1000 ton-mile).

FEL = family emissions limit for the vehicle family (gal/1000 ton-mile).

Payload = the prescribed payload in tons for each regulatory subcategory as shown in the following table:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Regulatory subcategory	Payload (Tons)
Vocational LHD Vehicles	2.85
Vocational MHD Vehicles	5.60
Vocational HHD Vehicles	7.5
MDH Tractors	12.50
HHD Tractors, other than heavy-haul Tractors	19.00
Heavy-haul Tractors	43.00

Volume = the number of U.S.-directed production volume of vehicles in the corresponding vehicle family.

UL = the useful life for the regulatory subcategory (miles) as shown in the following table:

Regulatory subcategory	UL (miles)
LHD Vehicles	110,000 (Phase 1) 150,000 (Phase 2)
Vocational MHD Vehicles and tractors at or below 33,000 pounds GVWR	185,000
Vocation HHD Vehicles and tractors at or above 33,000 pounds GVWR	435,000

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

* * * *

(d) * * *

(1) * * *

$$\text{Engine Family FCC (gallons)} = (\text{Std} - \text{FCL}) \times (\text{CF}) \times (\text{Volume}) \times (\text{UL}) \times (10^{-2})$$

Where:

Std = the standard for the respective engine regulatory subcategory (gal/100 hp-hr).

FCL = family certification level for the engine family (gal/100 hp-hr).

CF= a transient cycle conversion factor in hp-hr/mile which is the integrated total cycle horsepower-hour divided by the equivalent mileage of the applicable test cycle. For engines subject to spark-ignition heavy-duty standards, the equivalent mileage is 6.3 miles. For engines subject to compression-ignition heavy-duty standards, the equivalent mileage is 6.5 miles.

Volume = the number of engines in the corresponding engine family.

UL = the useful life of the given engine family (miles) as shown in the following table:

Regulatory Subcategory	UL (miles)
SI and CI LHD Engines	120,000 (Phase 1)
	150,000 (Phase 2)
CI MHD Engines	185,000
CI HHD Engines	435,000

* * * *

(e) * * *

(2) * * *

$$\text{Vehicle Family FCC (gallons)} = (\text{Std} - \text{FEL}) \times (\text{Payload}) \times (\text{Volume}) \times (\text{UL}) \times (10^{-3})$$

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Where:

Std = the standard for the respective vehicle family regulatory subcategory (gal/1000 ton-mile).

FEL = family emissions limit for the vehicle family (gal/1000 ton-mile).

Payload = 10 tons for short box vans and 19 tons for other trailers.

Volume = the number of U.S.-directed production volume of vehicles in the corresponding vehicle family.

UL = the useful life for the regulatory subcategory. The useful life value for heavy-duty trailers is equal to 250,000 miles.

* * * * *

(f) * * *

(2) * * *

(iii) * * *

(E) * * *

Off-cycle FC credits = (CO₂ Credit/CF) × Production × VLM

Where:

CO₂ Credits = the credit value in grams per mile determined in 40 CFR 86.1869-12(c)(3), (d)(1), (d)(2) or (d)(3).

CF = conversion factor, which for spark-ignition engines is 8,887 and for compression-ignition engines is 10,180.

Production = the total production volume for the applicable category of vehicles

VLM = vehicle lifetime miles, which for 2b-3 vehicles shall be 150,000 for the Phase 2

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

program.

The term (CO₂ Credit/CF) should be rounded to the nearest 0.0001

* * * * *

PART 536 – TRANSFER AND TRADING OF FUEL ECONOMY CREDITS

13. The authority citation for part 536 is revised to read as follows:

Authority: 49 U.S.C. 32903; delegation of authority at 49 CFR 1.95.

14. Amend § 536.4 by revising paragraph (c) to read as follows:

§ 536.4 Credits.

* * * * *

(c) Adjustment factor. When traded or transferred and used, fuel economy credits are adjusted to ensure fuel oil savings is preserved. For traded credits, the user (or buyer) must multiply the calculated adjustment factor by the number of shortfall credits it plans to offset in order to determine the number of equivalent credits to acquire from the earner (or seller). For transferred credits, the user of credits must multiply the calculated adjustment factor by the number of shortfall credits it plans to offset in order to determine the number of equivalent credits to transfer from the compliance category holding the available credits. The adjustment factor is calculated according to the following formula:

$$\underline{A} = \frac{VMT_u * MPG_{ae} * MPG_{se}}{VMT_e * MPG_{au} * MPG_{su}}$$

Where:

\underline{A} = Adjustment factor applied to traded and transferred credits. The quotient shall be rounded to 4 decimal places;

* * * * *

15. Amend § 536.5 by revising paragraph (c) and revising paragraph (d)(6) to read as follows:

§ 536.5 Trading infrastructure.

* * * * *

(c) Automatic debits and credits of accounts.

(1) To carry credits forward, backward, transfer credits, or trade credits into other credit accounts, a manufacturer or credit holder must submit a credit instruction to NHTSA. A credit instruction must detail and include:

(i) The credit holder(s) involved in the transaction.

(ii) The originating credits described by the amount of the credits, compliance category and the vintage of the credits.

(iii) The recipient credit account(s) for banking or applying the originating credits described by the compliance category(ies), model year(s), and if applicable the adjusted credit amount(s) and adjustment factor(s).

(iv) For trades, a contract authorizing the trade signed by the manufacturers or credit holders or by managers legally authorized to obligate the sale and purchase of the traded credits.

(2) Upon receipt of a credit instruction from an existing credit holder, NHTSA verifies the presence of sufficient credits in the account(s) of the credit holder(s) involved as applicable and notifies the credit holder(s) that the credits will be debited from and/or credited to the accounts involved, as specified in the credit instruction. NHTSA determines if the credits can be debited or credited based upon the amount of available credits, accurate application of any

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

adjustment factors and the credit requirements prescribed by this part that are applicable at the time the transaction is requested.

(3) After notifying the credit holder(s), all accounts involved are either credited or debited, as appropriate, in line with the credit instruction. Traded credits identified by a specific compliance category are deposited into the recipient's account in that same compliance category and model year. If a recipient of credits as identified in a credit instruction is not a current account holder, NHTSA establishes the credit recipient's account, subject to the conditions described in 49 CFR § 536.5(b), and adds the credits to the newly-opened account.

(4) NHTSA will automatically delete unused credits from holders' accounts when those credits reach their expiry date.

(5) Starting in model year 2021, manufacturers or credit holders issuing credit instructions or providing credit allocation plans as specified in 49 CFR § 536.5(d), must use the NHTSA Credit Template fillable form (OMB Control No. 2127-0019, NHTSA Form 1475). The NHTSA Credit Template is available for download on NHTSA's website. If a credit instruction includes a trade, the NHTSA Credit Template must be signed by managers legally authorized to obligate the sale and/or purchase of the traded credits from both parties to the trade. The NHTSA Credit Template signed by both parties to the trade serves as an acknowledgement that the parties have agreed to trade credits, and does not dictate terms, conditions, or other business obligations of the parties. All parties trading credits must also provide NHTSA the price paid for the credits including a description of any other monetary or non-monetary terms affecting the price of the traded credits, such as any technology exchanged or shared for the credits, any other non-monetary payment for the credits, or any other agreements related to the trade. Manufacturers must submit this information to NHTSA in a PDF document along with the

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Credit Template through the CAFE email, cafe@dot.gov. NHTSA reserves the right to request additional information from the parties regarding the terms of the trade.

(6) NHTSA will consider claims that information submitted to the agency under this section is entitled to confidential treatment under 5 U.S.C. 552(b) and under the provisions of 49 CFR Part 512 if the information is submitted in accordance with the procedures of that part.

* * * * *

(d) * * * * *

(6) Credit allocation plans received from a manufacturer will be reviewed and approved by NHTSA. Starting in model year 2021, use the NHTSA Credit Template (OMB Control No. 2127-0019, NHTSA Form 1475) to record the credit transactions requested in the credit allocation plan. The template is a fillable form that has an option for recording and calculating credit transactions for credit allocation plans. The template calculates the required adjustments to the credits. The credit allocation plan and the completed transaction template must be submitted to NHTSA. NHTSA will approve the credit allocation plan unless it finds that the proposed credits are unavailable or that it is unlikely that the plan will result in the manufacturer earning sufficient credits to offset the subject credit shortfall. If the plan is approved, NHTSA will revise the respective manufacturer's credit account accordingly. If the plan is rejected, NHTSA will notify the respective manufacturer and request a revised plan or payment of the appropriate fine.

PART 537 – AUTOMOTIVE FUEL ECONOMY REPORTS

16. The authority citation for part 537 is revised to read as follows:

Authority: 49 U.S.C. 32907; delegation of authority at 49 CFR 1.95.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

17. Amend § 537.5 by redesignating paragraph (d) as paragraph (e) and adding a new paragraph (d) to read as follows:

§ 537.5 General requirements for reports.

* * * * *

(d) Beginning with model year 2023, each manufacturer shall generate reports required by this part using the NHTSA CAFE Projections Reporting Template (OMB Control No. 2127–0019, NHTSA Form 1474). The template is a fillable form.

(1) Select the option to identify the report as a pre-model year report, mid-model year report, or supplementary report as appropriate;

(2) Complete all required information for the manufacturer and for all vehicles produced for the current model year required to comply with CAFE standards. Identify the manufacturer submitting the report, including the full name, title, and address of the official responsible for preparing the report and a point of contact to answer questions concerning the report.

(3) Use the template to generate confidential and non-confidential reports for all the domestic and import passenger cars and light truck fleet produced by the manufacturer for the current model year. Manufacturers must submit a request for confidentiality in accordance with 49 CFR 512 to withhold projected production sales volume estimates from public disclosure. If the request is granted, NHTSA will withhold the projected production sales volume estimates from public disclosure until all the vehicles produced by the manufacturer have been made available for sale (usually one year after the current model year).

(4) Submit confidential reports and requests for confidentiality to NHTSA on CD-ROM in accordance with Part 537.12. Email copies of non-confidential (i.e., redacted) reports to NHTSA's secure email address: cafe@dot.gov. Requests for confidentiality must be submitted

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

in a PDF or MS Word format. Submit 2 copies of the CD-ROM to: Administrator, National Highway Traffic Administration, 1200 New Jersey Avenue SE, Washington, DC 20590, and submit emailed reports electronically to the following secure email address: cafe@dot.gov;

(5) Confidentiality Requests.

(i) Manufacturers can withhold information on projected production sales volumes under 5 U.S.C. 552(b)(4) and 15 U.S.C. 2005(d)(1). In accordance, the manufacturer must:

(A) Show that the item is within the scope of sections 552(b)(4) and 2005(d)(1);

(B) Show that disclosure of the item would result in significant competitive damage;

(C) Specify the period during which the item must be withheld to avoid that damage; and

(D) Show that earlier disclosure would result in that damage.

(ii) [Reserved]

(e) Each report required by this part must be based upon all information and data available to the manufacturer 30 days before the report is submitted to the Administrator.

18. Amend § 537.6 by revising paragraphs (b) and (c) to read as follows:

§ 537.6 General content of reports.

* * * * *

(b) Supplementary report. Except as provided in paragraph (c) of this section, each supplementary report for each model year must contain the information required by § 537.7(a)(1) and (a)(2), as appropriate for the vehicle fleets produced by the manufacturer, in accordance with § 537.8(b)(1), (2), (3), and (4) as appropriate.

(c) Exceptions. The pre-model year report, mid-model year report, and supplementary report(s) submitted by an incomplete automobile manufacturer for any model year are not

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

required to contain the information specified in § 537.7 (c)(4) (xv) through (xviii) and (c)(5).

The information provided by the incomplete automobile manufacturer under § 537.7(c) shall be according to base level instead of model type or carline.

19. Amend § 537.7 by revising paragraph (a) to read as follows:

§ 537.7 Pre-model year and mid-model year reports.

(a)(1) Provide a report with the information required by paragraphs (b) and (c) of this section for each domestic and import passenger automobile fleet, as specified in part 531 of this chapter, for the current model year.

(2) Provide a report with the information required by paragraphs (b) and (c) of this section for each light truck fleet, as specified in part 533 of this chapter, for the current model year.

(3) For model year 2023 and later, provide the information required by paragraphs (a)(1) and (2) for pre-model and mid-model year reports in accordance with the NHTSA CAFE Projections Reporting Template (OMB Control No. 2127–0019, NHTSA Form 1474). The required reporting template can be downloaded from NHTSA’s website.

* * * * *

20. Amend § 537.7 by revising paragraphs (b)(3), (c)(1), (c)(3), (c)(7)(i), (c)(7)(ii), and (c)(7)(iii) to read as follows:

§ 537.7 Pre-model year and mid-model year reports.

* * * * *

(b) * * * * *

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(3) State the projected required fuel economy for the manufacturer's passenger automobiles and light trucks determined in accordance with 49 CFR 531.5(c) and 49 CFR 533.5 and based upon the projected sales figures provided under paragraph (c)(2) of this section. For each unique model type and footprint combination of the manufacturer's automobiles, provide the information specified in paragraph (b)(3)(i) and (ii) of this section in tabular form. List the model types in order of increasing average inertia weight from top to bottom down the left side of the table and list the information categories in the order specified in paragraphs (b)(3)(i) and (ii) of this section from left to right across the top of the table. Other formats, such as those accepted by the EPA, which contain all the information in a readily identifiable format are also acceptable. For model year 2023 and later, for each unique model type and footprint combination of the manufacturer's automobiles, provide the information specified in paragraph (b)(3)(i) and (ii) of this section in accordance with the CAFE Projections Reporting Template (OMB Control No. 2127-0019, NHTSA Form 1474).

(i) In the case of passenger automobiles:

(A) Beginning model year 2013, base tire as defined in 49 CFR 523.2,

(B) Beginning model year 2013, front axle, rear axle, and average track width as defined in 49 CFR 523.2,

(C) Beginning model year 2013, wheelbase as defined in 49 CFR 523.2, and

(D) Beginning model year 2013, footprint as defined in 49 CFR 523.2.

(E) The fuel economy target value for each unique model type and footprint entry listed in accordance with the equation provided in 49 CFR Parts 531.

(ii) In the case of light trucks:

(A) Beginning model year 2013, base tire as defined in 49 CFR 523.2,

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(B) Beginning model year 2013, front axle, rear axle, and average track width as defined in 49 CFR 523.2,

(C) Beginning model year 2013, wheelbase as defined in 49 CFR 523.2, and

(D) Beginning model year 2013, footprint as defined in 49 CFR 523.2.

(E) The fuel economy target value for each unique model type and footprint entry listed in accordance with the equation provided in 49 CFR Parts 533.

* * * *

(c) * * *

(1) For each model type of the manufacturer's automobiles, provide the information specified in paragraph (c)(2) of this section in tabular form. List the model types in order of increasing average inertia weight from top to bottom down the left side of the table and list the information categories in the order specified in paragraph (c)(2) of this section from left to right across the top of the table. For model year 2023 and later, CAFE reports required by §537, shall for each model type of the manufacturer's automobiles, provide the information in specified in paragraph (c)(2) of this section in accordance with the NHTSA CAFE Projections Reporting Template (OMB Control No. 2127-0019, NHTSA Form 1474) and list the model types in order of increasing average inertia weight from top to bottom.

* * * *

(3) (Pre-model year reports only through model year 2022.) For each vehicle configuration whose fuel economy was used to calculate the fuel economy values for a model type under paragraph (c)(2) of this section, provide the information specified in paragraph (c)(4) of this section in accordance with the NHTSA CAFE Projections Reporting Template (OMB Control No. 2127-0019, NHTSA Form 1474).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

* * * * *

(7) * * *

(i) Provide a list of each air conditioning efficiency improvement technology utilized in your fleet(s) of vehicles for each model year. For each technology identify vehicles by make and model types that have the technology, which compliance category those vehicles belong to and the number of vehicles for each model equipped with the technology. For each compliance category (domestic passenger car, import passenger car, and light truck), report the air conditioning fuel consumption improvement value in gallons/mile in accordance with the equation specified in 40 CFR 600.510-12(c)(3)(i).

(ii) Provide a list of off-cycle efficiency improvement technologies utilized in your fleet(s) of vehicles for each model year that is pending or approved by the EPA. For each technology identify vehicles by make and model types that have the technology, which compliance category those vehicles belong to, the number of vehicles for each model equipped with the technology, and the associated off-cycle credits (grams/mile) available for each technology. For each compliance category (domestic passenger car, import passenger car, and light truck), calculate the fleet off-cycle fuel consumption improvement value in gallons/mile in accordance with the equation specified in 40 CFR 600.510-12(c)(3)(ii).

(iii) Provide a list of full-size pickup trucks in your fleet that meet the mild and strong hybrid vehicle definitions. For each mild and strong hybrid type, identify vehicles by make and model types that have the technology, the number of vehicles produced for each model equipped with the technology, the total number of full-size pickup trucks produced with and without the technology, the calculated percentage of hybrid vehicles relative to the total number of vehicles produced, and the associated full-size pickup truck credits (grams/mile) available for each

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

technology. For the light truck compliance category, calculate the fleet pickup truck fuel consumption improvement value in gallons/mile in accordance with the equation specified in 40 CFR 600.510-12(c)(3)(iii).

* * * * *

21. Amend § 537.8 by revising paragraph (a)(3), paragraph (b)(4) and paragraph (c)(1), and adding paragraphs (a)(4) and (b)(4) to read as follows:

§ 537.8 Supplementary reports.

(a) * * *

(3) For model years through 2022, each manufacturer whose pre-model or mid-model year report omits any of the information specified in § 537.7(b) or (c) shall file a supplementary report containing the information specified in paragraph (b)(3) of this section. Starting model year 2023, each manufacturer whose pre-model or mid-model year report omits any of the information shall resubmit the information with other information required in accordance with the NHTSA CAFE Projections Reporting Template (OMB Control No. 2127–0019, NHTSA Form 1474).

(b) * * *

(4) The supplementary report required by paragraph (a)(4) of this section must contain:

(i) All information omitted from the pre-model or mid-model year reports under § 537.6(c)(2); and

(ii) Such revisions of and additions to the information submitted by the manufacturer in its pre-model or mid-model year reports regarding the automobiles produced during the current

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

model year as are necessary to reflect the information provided under paragraph (b)(4)(i) of this section.

(c)(1) Each report required by paragraph (a)(1), (2), (3), or (4) of this section must be submitted in accordance with § 537.5(c) not more than 45 days after the date on which the manufacturer determined, or could have determined with reasonable diligence, that the report was required.

Environmental Protection Agency

40 CFR Chapter I

For the reasons set forth in the preamble, the Environmental Protection Agency is amending part 86 of title 40, Chapter I of the Code of Federal Regulations as follows:

PART 86—CONTROL OF EMISSIONS FROM NEW AND IN-USE HIGHWAY VEHICLES AND ENGINES

1. The authority citation for part 86 continues to read as follows:

Authority: 42 U.S.C. 7401-7671q.

2. Section 86.1818-12 is amended by revising paragraphs (c)(2)(i)(A) through (C) and (c)(3)(i)(A), (B), and (D), to read as follows:

§86.1818-12 Greenhouse gas emission standards for light-duty vehicles, light-duty trucks, and medium-duty passenger vehicles.

* * * * *

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(c) * * *

(2) * * *

(i) * * *

(A) For passenger automobiles with a footprint of less than or equal to 41 square feet, the gram/mile CO₂ target value shall be selected for the appropriate model year from the following table:

Model year	CO ₂ target value (grams/mile)
2012	244.0
2013	237.0
2014	228.0
2015	217.0
2016	206.0
2017	195.0
2018	185.0
2019	175.0
2020	166.0
2021	161.8
2022	159.0
2023	156.4
2024	153.7

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

2025	151.2
2026 and later	148.6

(B) For passenger automobiles with a footprint of greater than 56 square feet, the gram/mile CO₂ target value shall be selected for the appropriate model year from the following table:

Model year	CO ₂ target value (grams/mile)
2012	315.0
2013	307.0
2014	299.0
2015	288.0
2016	277.0
2017	263.0
2018	250.0
2019	238.0
2020	226.0
2021	220.9

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

2022	217.3
2023	213.7
2024	210.2
2025	206.8
2026 and later	203.4

(C) For passenger automobiles with a footprint that is greater than 41 square feet and less than or equal to 56 square feet, the gram/mile CO₂ target value shall be calculated using the following equation and rounded to the nearest 0.1 grams/mile, except that for any vehicle footprint the maximum CO₂ target value shall be the value specified for the same model year in paragraph (c)(2)(i)(B) of this section:

$$\text{Target CO}_2 = [a \times f] + b$$

Where:

f is the vehicle footprint, as defined in §86.1803; and a and b are selected from the following table for the appropriate model year:

Model year	a	b
2012	4.72	50.5
2013	4.72	43.3
2014	4.72	34.8
2015	4.72	23.4

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

2016	4.72	12.7
2017	4.53	8.9
2018	4.35	6.5
2019	4.17	4.2
2020	4.01	1.9
2021	3.94	0.2
2022	3.88	-0.1
2023	3.82	-0.4
2024	3.77	-0.6
2025	3.71	-0.9
2026 and later	3.65	-1.2

* * * * *

(3) * * *

(i) * * *

(A) For light trucks with a footprint of less than or equal to 41 square feet, the gram/mile CO₂ target value shall be selected for the appropriate model year from the following table:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Model year	CO ₂ target value (grams/mile)
2012	294.0
2013	284.0
2014	275.0
2015	261.0
2016	247.0
2017	238.0
2018	227.0
2019	220.0
2020	212.0
2021	206.6
2022	203.1
2023	199.7
2024	196.3
2025	193.0
2026 and later	189.8

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(B) For light trucks with a footprint that is greater than 41 square feet and less than or equal to the maximum footprint value specified in the table below for each model year, the gram/mile CO₂ target value shall be calculated using the following equation and rounded to the nearest 0.1 grams/mile, except that for any vehicle footprint the maximum CO₂ target value shall be the value specified for the same model year in paragraph (c)(3)(i)(D) of this section:

$$\text{Target CO}_2 = (a \times f) + b$$

Where:

f is the footprint, as defined in §86.1803; and a and b are selected from the following table for the appropriate model year:

Model year	Maximum footprint	a	b
2012	66.0	4.04	128.6
2013	66.0	4.04	118.7
2014	66.0	4.04	109.4
2015	66.0	4.04	95.1
2016	66.0	4.04	81.1
2017	50.7	4.87	38.3
2018	60.2	4.76	31.6
2019	66.4	4.68	27.7
2020	68.3	4.57	24.6

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

2021	73.5	4.51	21.7
2022	74.0	4.44	21.0
2023	74.0	4.38	20.3
2024	74.0	4.31	19.6
2025	74.0	4.25	19.0
2026 and later	74.0	4.18	18.3

* * * * *

(D) For light trucks with a footprint greater than the minimum value specified in the table below for each model year, the gram/mile CO₂ target value shall be selected for the appropriate model year from the following table:

Model year	Minimum footprint	CO ₂ target value (grams/mile)
2012	66.0	395.0
2013	66.0	385.0
2014	66.0	376.0
2015	66.0	362.0
2016	66.0	348.0

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

2017	66.0	347.0
2018	66.0	342.0
2019	66.4	339.0
2020	68.3	337.0
2021	73.5	329.7
2022	74.0	324.4
2023	74.0	319.2
2024	74.0	314.0
2025	74.0	308.9
2026 and later	74.0	303.9

* * * * *

3. Section 86.1866-12 is amended by revising paragraph (a)(2), removing paragraph (a)(3), revising (b) introductory text, revising (b)(1), and revising (b)(2)(i) to read as follows:

§86.1866-12 CO₂ credits for advanced technology vehicles.

* * * * *

(a) * * *

(2) Model years 2017 through 2026: For electric vehicles, plug-in hybrid electric vehicles, and fuel cell vehicles produced for U.S. sale, where “U.S.” means the states and

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

territories of the United States, in the 2017 through 2026 model years, such use of zero (0) grams/mile CO₂ is unrestricted.

(b) For electric vehicles, plug-in hybrid electric vehicles, fuel cell vehicles, dedicated natural gas vehicles, and dual-fuel natural gas vehicles as those terms are defined in §86.1803–01, that are certified and produced for U.S. sale in the specified model years and that meet the additional specifications in this section, the manufacturer may use the production multipliers in this paragraph (b) when determining the manufacturer’s fleet average carbon-related exhaust emissions under §600.512 of this chapter. Full size pickup trucks eligible for and using a production multiplier are not eligible for the performance-based credits described in §86.1870–12(b).

(1) The production multipliers, by model year, for model year 2017 through 2021 electric vehicles and fuel cell vehicles are as follows:

Model year	Production multiplier
2017	2.0
2018	2.0
2019	2.0
2020	1.75
2021	1.5

(2)(i) The production multipliers, by model year, for model year 2017 through 2021 plug-in hybrid electric vehicles and model year 2017 through 2026 dedicated natural gas vehicles and dual-fuel natural gas vehicles are as follows:

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Model year	Production multiplier
2017	1.6
2018	1.6
2019	1.6
2020	1.45
2021	1.3
2022-2026 (dedicated and dual fuel natural gas vehicles only)	2.0

* * * * *

4. Section 86.1868-12 is amended by inserting a row at the bottom of the table in paragraph (a)(2) and by adding paragraph (h)(7) to read as follows:

§86.1868-12 CO₂ credits for improving the efficiency of air conditioning systems.

* * * * *

(a) * * *

(2) * * *

Air conditioning technology	Passenger	Light
	automobiles	trucks
	(g/mi)	(g/mi)

* * * * *		
Advanced technology air conditioning compressor with improved efficiency relative to fixed-displacement compressors achieved through the addition of a variable crankcase suction valve.	1.1	1.1

* * * * *

(h) * * *

(7) *Advanced technology air conditioning compressor* means an air conditioning compressor with improved efficiency relative to fixed-displacement compressors. Efficiency gains are derived from improved internal valve systems that optimize the internal refrigerant flow across the range of compressor operator conditions through the addition of a variable crankcase suction valve.

5. Section 86.1869-12 is amended by revising paragraph (a), by adding paragraphs (b)(1)(ix), (b)(1)(x), (b)(4)(xiii) and (b)(4)(xiv), and by revising paragraph (d)(2) to read as follows:

§86.1869-12 CO₂ credits for off-cycle CO₂ reducing technologies.

* * * * *

(a) Manufacturers may generate credits for CO₂-reducing technologies where the CO₂ reduction benefit of the technology is not adequately captured on the Federal Test Procedure and/or the Highway Fuel Economy Test such that the technology would not be otherwise installed for purposes of reducing emissions (directly or indirectly) over those test cycles for

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

compliance with the GHG standards. These technologies must have a measurable, demonstrable, and verifiable real-world CO₂ reduction that occurs outside the conditions of the Federal Test Procedure and the Highway Fuel Economy Test. These optional credits are referred to as “off-cycle” credits. The technologies must not be integral or inherent to the basic vehicle design, such as engine, transmission, mass reduction, passive aerodynamic design, and tire technologies. Technologies installed for non-off-cycle emissions related reasons are also not eligible as they would be considered part of the baseline vehicle design. The technology must not be inherent to the design of occupant comfort and entertainment features except for technologies related to reducing passenger air conditioning demand and improving air conditioning system efficiency. Notwithstanding the provisions of this paragraph (a), off-cycle menu technologies included in paragraph (b) of this section remain eligible for credits. Off-cycle technologies used to generate emission credits are considered emission-related components subject to applicable requirements and must be demonstrated to be effective for the full useful life of the vehicle. Unless the manufacturer demonstrates that the technology is not subject to in-use deterioration, the manufacturer must account for the deterioration in their analysis. Durability evaluations of off-cycle technologies may occur at any time throughout a model year, provided that the results can be factored into the data provided in the model year report. Off-cycle credits may not be approved for crash-avoidance technologies, safety critical systems or systems affecting safety-critical functions, or technologies designed for the purpose of reducing the frequency of vehicle crashes. Off-cycle credits may not be earned for technologies installed on a motor vehicle to attain compliance with any vehicle safety standard or any regulation set forth in Title 49 of the Code of Federal Regulations. The manufacturer must use one of the three options specified in this section to determine the CO₂ gram per mile credit applicable to an off-cycle technology.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

Note that the option provided in paragraph (b) of this section applies only to the 2014 and later model years. The manufacturer should notify EPA in their pre-model year report of their intention to generate any credits under this section.

(b) * * *

(1) * * *

(ix) *High efficiency alternator*. The credit for a high efficiency alternator for passenger automobiles and light trucks shall be calculated using the following equation, and rounded to the nearest 0.1 grams/mile:

$$Credit\left(\frac{g}{mi}\right) = (VDA_{HEA} - 67) \times 0.16$$

Where:

VDA_{HEA} is the ratio of the alternator output power to the power supplied to the alternator, as measured using the Verband der Automobilindustrie (VDA) efficiency measurement methodology and expressed as a whole number percent from 68 to 100.

* * * * *

(4) * * *

(xiii) *High efficiency alternator* means an alternator where the ratio of the alternator output power to the power supplied to the alternator is greater than 67 percent, as measured using the Verband der Automobilindustrie (VDA) efficiency measurement methodology.

* * * * *

(d) * * *

(2) *Notice and opportunity for public comment*.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(i) The Administrator will publish a notice of availability in the Federal Register notifying the public of a manufacturer's proposed alternative off-cycle credit calculation methodology. The notice will include details regarding the proposed methodology but will not include any Confidential Business Information. The notice will include instructions on how to comment on the methodology. The Administrator will take public comments into consideration in the final determination and will notify the public of the final determination. Credits may not be accrued using an approved methodology until the first model year for which the Administrator has issued a final approval.

(ii) The Administrator may waive these notice and comment requirements for technologies for which EPA has previously approved a methodology for determining credits. To qualify for this waiver, the new application must be substantially identical in form, content, and methodology to the application for a previously approved methodology, and must include the following:

(A) A cite to the appropriate previously approved methodology, including the appropriate Federal Register Notice and any subsequent EPA documentation of the Administrator's decision;

(B) All necessary manufacturer- and vehicle-specific test data, modeling, and credit calculations; and,

(C) Any other vehicle- or technology-specific details required pursuant to the previously approved methodology to assess and support an appropriate credit value.

(iii) A waiver of the notice and comment requirements does not imply a determination that a specific credit value for a given technology is appropriate, and nor does it imply a waiver from the requirements in paragraphs (d)(1) and (e) of this section.

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(iv) The Administrator retains the option to require a notice and opportunity for public comment in cases where a new application deviates in significant respects from a previously approved methodology or raises novel substantive issues.

* * * * *

6. Section 600.113-12 is amended by revising paragraphs (n) introductory text, (n)(1), and (n)(3) to read as follows:

§600.113-12 Fuel economy, CO₂ emissions, and carbon-related exhaust emission calculations for FTP, HFET, US06, SC03 and cold temperature FTP tests.

* * * * *

(n) Manufacturers shall determine CO₂ emissions and carbon-related exhaust emissions for electric vehicles, fuel cell vehicles, and plug-in hybrid electric vehicles according to the provisions of this paragraph (n). Subject to the limitations on the number of vehicles produced and delivered for sale as described in §86.1866 of this chapter, the manufacturer may be allowed to use a value of 0 grams/mile to represent the emissions of fuel cell vehicles and the proportion of electric operation of a electric vehicles and plug-in hybrid electric vehicles that is derived from electricity that is generated from sources that are not onboard the vehicle, as described in paragraphs (n)(1) through (3) of this section. For purposes of labeling under this part, the CO₂ emissions for electric vehicles shall be 0 grams per mile. Similarly, for purposes of labeling under this part, the CO₂ emissions for plug-in hybrid electric vehicles shall be 0 grams per mile for the proportion of electric operation that is derived from electricity that is generated from sources that are not onboard the vehicle. For all 2027 and later model year electric vehicles, fuel

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

cell vehicles, and plug-in hybrid electric vehicles, the provisions of this paragraph (n) shall be used to determine the non-zero value for CREE for purposes of meeting the greenhouse gas emission standards described in §86.1818 of this chapter.

(1) For electric vehicles, but not including fuel cell vehicles, the carbon-related exhaust emissions in grams per mile is to be calculated using the following equation and rounded to the nearest one gram per mile:

$$CREE = CREEUP - CREEGAS$$

Where:

CREE means the carbon-related exhaust emission value as defined in §600.002, which may be set equal to zero for eligible 2012 through 2026 model year electric vehicles as described in §86.1866-12(a) of this chapter.

$$CREE_{UP} = \frac{EC}{GRIDLOSS} \times AVGUSUP, \text{ and}$$

$$CREE_{GAS} = \frac{2478}{8887} \times TargetCO_2,$$

Where:

EC = The vehicle energy consumption in watt-hours per mile, for combined FTP/HFET operation, determined according to procedures established by the Administrator under §600.116-12.

GRIDLOSS = 0.935 (to account for grid transmission losses).

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

AVGUSUP = 0.534 (the nationwide average electricity greenhouse gas emission rate at the powerplant, in grams per watt-hour).

2478 is the estimated grams of upstream greenhouse gas emissions per gallon of gasoline.

8887 is the estimated grams of CO₂ per gallon of gasoline.

TargetCO₂ = The CO₂ Target Value for the fuel cell or electric vehicle determined according to §86.1818 of this chapter for the appropriate model year.

* * * * *

(3) For 2012 and later model year fuel cell vehicles, the carbon-related exhaust emissions in grams per mile shall be calculated using the method specified in paragraph (n)(1) of this section, except that CREEUP shall be determined according to procedures established by the Administrator under §600.111-08(f). As described in §86.1866 of this chapter, the value of CREE may be set equal to zero for 2012 through 2026 model year fuel cell vehicles.

* * * * *

7. Section 600.510-12 is amended by revising paragraphs (c)(2)(vi) introductory text, by inserting paragraph (c)(2)(vii) introductory text, by revising paragraph (c)(2)(vii)(B) introductory text, by revising (j)(2)(v) introductory text, by inserting paragraph (j)(2)(vi) introductory text, and by revising paragraph (j)(2)(vi)(B) introductory text to read as follows:

§600.510-12 Calculation of average fuel economy and average carbon-related exhaust emissions.

* * * * *

(c) * * *

*** EO 12866 Review Draft Do Not Cite, Quote or Release During Review ***

(2) * * *

(vi) For natural gas dual fuel model types, for model years 1993 through 2016, and optionally for 2021 and later model years, the harmonic average of the following two terms; the result rounded to the nearest 0.1 mpg:

* * * * *

(vii) This paragraph (c)(2)(vii) applies to model year 2017 through 2020 natural gas dual fuel model types. Model year 2021 and later natural gas dual fuel model types may use the provisions of paragraph (c)(2)(vi) of this section or this paragraph (c)(2)(vii).

* * * * *

(B) Model year 2017 through 2020 natural gas dual fuel model types must meet the following criteria to qualify for use of a Utility Factor greater than 0.5:
